This is the general Structure of the Flowers of Plants, altho' they are infinite Ways diverſify'd, and to ſuch a Degree, that ſome have no ſenſible *Piſtil*, and others want the *Stamina*; others again have the *Stamina*, but want the *Apices*; and ſome Plants exceed all others in this, that they have no Flowers: But if it be allow'd, that this before-mention'd be the moſt common Structure of Flowers, it will follow, that theſe Parts that ſeem wanting are uſually only leſs apparent.

The Fruit is uſually at the Baſe of the *Piſtillum*; ſo that when the *Piſtillum* falls with the reſt of the Flower, the Fruit appears in the ſtead of it: But oftentimes the *Piſtillum* is the Fruit itſelf; but ſtill they have both the ſame Situation in the Center of the Flower; and the *Petala*, or Flower-leaves, which are diſpos'd around the little *Embryo*, ſeem to be deſign'd only to prepare a fine Juice in the little Veſſels, for the Support of it during the little Time that they laſt, and it requires: But ſome ſuppoſe the chief Uſe of them to be to defend the *Piſtillum*, &c.

The *Apices* of the *Stamina* are ſmall *Capſulæ*, or Bags full of a *Farina* or Duſt, which falls out when the *Capſula* grows ripe, and burſts.

Monſ. *Tournefort* ſuppos'd this Duſt to be only an Excrement of the Food of the Fruit; and the *Stamina* to be but only excretory Ducts, which filtrated this uſeleſs Matter, and thus diſcharg'd the *Embryo*: But Mr. *Morland*, Mr. *Geoffroy*, and others, find nobler Uſes for this Duſt. On their Principle, the *Stamina*, with the *Apices* and *Farina*, make the Male Part of the Plant; and the *Piſtil*, the Female.

Mr. *Morland* ſays, It hath been long ago obſerv'd, that there is in every particular Seed a ſeminal Plant conveniently lodg'd between the two Lobes, which conſtitute the Bulk of the Seed, and are deſign'd for the firſt Nouriſhment of the tender Plant.

But the admirable Dr. *Grew*, to whoſe generous Induſtry and happy Sagacity we are indebted for the beſt Improvements of this Part of Knowledge, is the only Author I can find, who hath obſerv'd, that the *Farina*, or fine Powder, which is at its proper Seaſon, ſhed out of thoſe *Thecæ*, or *Apices ſeminiformes*, [*i. e.* Seed-forming Caſes] which grow at the Top of the *Stamina*, doth ſome Way perform the Office of Male Sperm. But herein, I think, he falls ſhort, in that he ſuppoſes them only to drop upon the Outſide or *Uterus*, or *Vaſculum Seminale*, and to impregnate the included Seed by ſome ſpirituous Emanations, or energetical Impreſs.

That which is now ſubjected to the Diſquiſitions and Cenſure of ſuch whoſe exquiſite Skill doth conſtitute them Judges of ſuch Performances, is, whether it be not more proper to ſuppoſe that the Seeds which come up in their proper *Involucra*, are at the firſt unimpregnated *Ova* (or Eggs) of Animals; that this *Farina* is a *Congeries* of ſeminal Plants, one of which muſt be convey'd into every *Ovum* before it can become prolifick: That the *Stylus*, in Mr. *Ray*'s Language, or the upper Part of the *Piſtillum*, in Mr. *Tournefort*'s, is a Tube deſigned to convey theſe ſeminal Plants into their Neſts in the *Ova*: That there is ſo vaſt a Proviſion made, becauſe of the Odds there are, whether one, of ſo many, ſhall ever find its Way into and thro' ſo narrow a Conveyance.

To make this Suppoſition the more credible, I ſhall lay down the Obſervations I have made upon the Situation of theſe *Stamina* and the *Stylus* in ſome few Species of Plants.

Firſt, In the *Corona Imperialis*, where the *Uterus* or *Vaſculum Seminale* of the Plant ſtands upon the Center of the Flower; and from the Top of this ariſeth the *Stylus*, the *Vaſculum Seminale* and *Stylus* together repreſenting a *Piſtillum*.

Round this are placed ſix *Stamina*; upon the Ends of each of theſe are *Apices*, ſo artfully fixed, that they turn every Way with the leaſt Wind, being in Height almoſt exactly equal to the *Stylus* about which they play, and which in this Plant is manifeſtly open at the Top, as it is hollow all the Way: To which we muſt add, that upon the Top of the *Stylus* there is a Sort of *Tuft* conſiſting of pinguid *Villi*, which I imagined to be placed there to catch and detain the *Farina* as it flies out of the *Thecæ*; from hence, I ſuppoſe, the Wind ſhakes it down the Tube, 'till it reach the *Vaſculum Seminale*.

In the *Caprifolium*, or *Honey-ſuckle*, there riſes a *Stylus* from the Rudiments of a Berry, into which it is inſerted, to the Top of the monopetalous Flower; from the Middle of which Flower are ſent forth ſeveral *Stamina*, that ſhed their *Farina* out of the Caſes upon the Orifice of the *Stylus*, which, in this Plant, is villous or tufted, upon the ſame Account as in the former.

In *Allium*, or *common Garlick*, there ariſes a *tricoccous Uterus*, or Seed-veſſel; in the Center of which is inſerted a ſhort *Stylus*, not reaching ſo high as the *Apices*, which thus over-topping it, have the Opportunity of ſhedding their Globules into an Orifice more eaſily: For which Reaſon, I can diſcern no Tuft upon this (as in the former) to inſure their Entrance, that being provided for, by its Situation juſt under them.

The Reader, I hope, will excuſe me, if I preſent him now with ſome ſuch Reaſonings or Reflections as the foregoing Account doth ſuggeſt, and will ſupport; and I can't but hope to perſuade thoſe that are candid, that I have aſſign'd to the ſeveral Parts of the Flowers I have mention'd, their true and real Uſe.

For nothing can be more natural than to conclude, that where a fine Powder is curiouſly prepar'd, carefully repoſited, and ſhed abroad at a peculiar Seaſon, where there is a Tube ſo planted as to be fit to receive it; and ſuch Care in diſpoſing this Tube, that where it doth not lie directly under the Caſes that ſhed the Powder, it hath a particular *Apparatus* at the End to inſure its Entrance.

Nothing can be more genuinely deduced from any Premiſes, than it may from this, that this Powder, or ſome of it, was deſigned to enter this Tube. If theſe *Stamina* had been only excretory Ducts, as has been hitherto ſuppoſed, to ſeparate the groſſer Parts, and leave the Juice deſigned for the Nouriſhment of the Seed more reſerved, what Need was there to lodge theſe Excrements in ſuch curious Repoſitories? They would have been convey'd any-where, rather than where there was ſo much Danger of their dropping into the *Seed-veſſel* again, as they are here.

Again: The Tube over the Mouth of which they are ſhed, and into which they enter, leads always directly into the Seed-veſſel.

To which we muſt add, that the *Tube* always begins to die when theſe *Thecæ* are empty'd of their Contents: If they laſt any longer, it is only whilſt the Globules, which enter at their Orifice, may be ſuppos'd to have finiſh'd their Paſſage. Now, can we well expect a more convincing Proof of theſe *Tubes* being deſigned to convey theſe *Globules*, than that they wither when there are not more *Globules* to convey?

If I could now ſhew, that the *Ova*, or unimpregnated Seed, are ever to be obſerved without this *ſeminal Plant*, the Proof would ariſe to a Demonſtration; but having not been ſo happy as to obſerve this, I ſhall content myſelf at preſent with ſuggeſting, that hence one would conclude, that the *Petala* of the Flower were rather deſigned to ſever ſuperfluous Juices from what was left to aſcend in the *Stamina*, than the *Stamina* to perform this Office, either for them, or the unimpregnated *Semina*, and obſerve the Analogy between *Animal* and *Vegetable Generation*, as far as was neceſſary there ſhould be an Agreement between them. I ſhall recommend the Inquiry to thoſe Gentlemen who are Maſters of the beſt Microſcopes, and Addreſs in uſing them; tho', in the mean Time, I have made ſome Steps towards a Proof this Sort, and have met with ſome ſuch Hints, as make me not deſpair of being able, in a ſhort Time to give the World even this Satisfaction.

For not to inſiſt upon this, that the *Seminal Plant* always lies in that Part of the Seed which is always neareſt to the Inſertion of this *Stylus*, or ſome Propagation of it into the Seed-veſſels, I have diſcover'd in *Beans*, *Peaſe*, and *Phaſeols*, juſt under one End of what we call the *Eye*, a manifeſt Perforation (diſcernible by the groſſer Sort of magnifying Glaſſes) which leads directly to the *Seminal Plant*, and at which I ſuppoſe the *Seminal Plant* did enter; and I am apt to think, the *Beans* or *Peaſe* that don't thrive well, may be found deſtitute of it.

But I muſt now proceed to deſcribe ſome other Plants, whereby it will appear, that there is a particular Care always exercis'd to convey this Powder, ſo often mention'd, into a *Tube*, which may convey it to the *Ova*.

Now, in *Leguminous Plants*, if we carefully take off the *Petala* of the Flower, we ſhall diſcover the *Pod* or *Siliqua* cloſely cover'd with an involving Membrane, which, about the Top, ſeparates into ſeveral *Stamina*, each fraught with its Quantity of *Farina*; and theſe *Stamina* are cloſely bound upon the Bruſh, which is obſervable at the End of that *Tube*, which here alſo leads directly to the Pod: It ſtands not upright, indeed, but ſo bended as to make near a right Angle with it.

In *Roſes* there ſtands a Column, conſiſting of many *Tubes* cloſely clung together, tho' eaſily ſeparable, each leading to their particular Cell, the *Stamina* in a great Number planted all round about.

In *Tithymalus*, or *Spurge*, there riſes a tricoccous Veſſel, that, whilſt it is ſmall, and not eaſily diſcernible, lies at the Bottom 'till it is impregnated; but afterwards grows up, and ſtands ſo high upon a tall Pedicle of its own, as would tempt one to think, that there were to be no Communion betwixt this and the *Apices*.

In the *Straw-berries* and *Raſp-beries*, the Hairs which grow upon the ripe Fruit, (which, I ſuppoſe, may be ſurprizing to ſome) are ſo many *Tubes* leading each to their particular Seed; and therefore we may obſerve, that in the firſt opening of the Flower there ſtands a Ring of *Stamina* within the *Petala*, and the whole inward *Area* appears like a little Wood of theſe Hairs or Pulp; which when they have receiv'd and convey'd their *Globules*, the Seeds ſwell, and riſe in a carneous Pulp. Thus far Mr. *Morland*.

We may obſerve a Veſſel at the Bottom of the *Piſtil* of the *Lily*, which Veſſel we may call the *Uterus* or *Womb*; in which are three *Ovaries* fill'd with little Eggs or Rudiments of Seed found in the *Ovaria*, which always decay and come to nothing, unleſs impregnated with the *Farina* of the ſame Plant, or ſome other of the ſame Kind: The *Stamina* alſo ſerve for the Conveyance of the Male Seed of the Plant to be perfected in the *Apices*; which, when ripe, burſt forth in little Particles like Duſt: Some of them fall into the Orifice of the *Piſtil*, and are either convey'd thence into the *Utricle*, to fecundify the Female *Ova*, or lodg'd in the *Piſtil*, where, by their magnetick Virtue, they draw the Nouriſhment from the other Parts of the Plant into the *Embryo's* of the Fruit, making them ſwell, grow, *&c.*

In Flowers that turn down, as the *Cyclamen*, and the *Imperial Crown*, the *Piſtil* is much longer than the *Stamina*, that the Duſt may fall from their *Apices* in ſufficient Quantities on the *Piſtil*, for the Buſineſs of Impregnation.

Mr. *Geoffroy* aſſures us, that in all the Obſervations he had made, the cutting off the *Piſtil* before it could be impregnated by the *Farina*, actually render'd the Plant barren for that Seaſon, and the Fruit abortive.

In many Kinds of Plants, as the *Oak*, *Pine*, *Willow*, &c. the Flowers, Mr. *Geoffroy* obſerves, have their *Stamina* and *Apices*, whoſe *Farina* may eaſily impregnate the Rudiments of the Fruit, which are not far off.

Indeed there is ſome Difficulty in reconciling this Syſtem with a certain Species of Plants, which bear Flowers without Fruit; and another Species of the ſame Kind and Denomination, which bear Fruit without Flowers; ſuch are the *Palm*, *Hemp*, *Hop*, *Poplar*, &c. which are hence diſtinguiſh'd into *Male* and *Female*: For how ſhould the *Farina* of the Male here come to impregnate the *Ova* of the Female?

This Difficulty Mr. *Geoffroy* ſolves, by ſuppoſing the Wind to be the Vehicle that conveys the Male *Duſt* to the Female *Uterus*; which is confirm'd by an Inſtance of *Jovianus Pontanus*, of a ſingle Female *Palm-tree* growing in a Foreſt, which never bore Fruit, till having riſen above the other Trees of the Foreſt, and being then in a Condition to receive the *Farina* of the Male by the Wind, it began to bear Fruit in abundance.

As to the Manner wherein the *Farina* fecundifies, Mr. *Geoffroy* advances two Opinions:

1ſt, That the *Farina* being always found of a ſulphurous Compoſition, and full of ſubtil and penetrating Parts, (as appears from its ſprightly Odour) which falling on the Piſtils of the Flowers, there reſolves, and the ſubtileſt Parts of it penetrating the Subſtance of the Piſtil, excite a Fermentation, which putting the latent Juices of the young Fruit in Motion, occaſions the Parts to unfold the young Plant that is inclos'd in the Embryo of the Seed.

In this Hypotheſis, the Plant in Miniature is ſuppos'd to be contain'd in the Seed, and to want only a proper Juice to unfold its Parts, and make them grow.

The ſecond Opinion is, That the *Farina* of the Male Plant is the firſt Germ or *Semen* of the new Plant, and ſtands in need of nothing to enable it to grow or unfold, but a ſuitable *Nidus* with the Juice it finds prepar'd in the Embryo of the Seed or Ovary.

It may be obſerv'd, that theſe two Theories of *Vegetable Generation* bear a ſtrict Analogy to thoſe two of *Animal Generation*, viz. either that the young Animal is in the *Semen Maſculinum*, and only ſtands in need of the Juice of the Matrix to cheriſh and bring it forth; or that the Female *Ovum* contains the Animal, and requires only the Male Seed to excite a Fermentation.

Mr. *Geoffroy* rather takes the proper Seed to be in the *Farina*; inaſmuch as the beſt Microſcopes don't diſcover the leaſt Appearance of any Bud in the little Embryo's of the Grains, when they are examin'd, before the Apices have ſhed their Duſt.

In leguminous Plants, if the *Petala* and *Stamina* be remov'd, and the Piſtil, or that Part which becomes the Pod, be view'd with the Microſcope before the Flower be open, thoſe little, green, tranſparent *Veſiculæ*, which are to become Grains, will appear in their natural Order, yet ſtill ſhewing nothing elſe but the mere Coat or Skin of the Grain.

If you continue to obſerve the Flowers as they advance for ſeveral Days ſucceſſively, you'll find them to ſwell, and by Degrees to become replete with a limpid Liquor; in which, when the *Farina* comes to be ſhed, and the Leaves of the Flower to fall, there may be obſerv'd a little greeniſh Speck or Globule floating about at large.

There is not at firſt any Appearance of an Organization in this little Body; but in time, as it grows, you may begin to diſtinguiſh two little Leaves like two ſmall Horns: As the little Body grows, the Liquor diminiſhes inſenſibly, till at length the Grain becomes quite opake; and upon opening it, the Cavity will be found fill'd with a young Plant in Miniature, conſiſting of a little *Germ* or *Plantula*, a little Root, and the Lobes of the Bean or Pea.

The Manner wherein this Germ of the *Apex* enters the *Veſicula* of the Grain, is not very difficult to determine: For beſides that the Cavity of the Piſtil reaches from the Top to the Embryo's of the Grains, thoſe Grains or *Veſiculæ* have a little Aperture correſponding to the Extremity of the Cavity of the Piſtil, ſo that the ſmall Duſt or *Farina* may eaſily fall, or find an eaſy Paſſage in the Aperture in the Mouth of the Veſſels, which is the Embryo of the Grain.

This Aperture or *Cicatricula* is much the ſame in both Grains, and it is eaſily obſerv'd in Peas, Beans, *&c.* without a Microſcope.

The Root of the little Germ is juſt againſt this Aperture, and it is through this it paſſes out when the little Grain comes to germinate.

Dr. *Patrick Blair*, treating of the *Generation of Plants*, ſays, That a Vegetative Life is common to them, as well as *Animals*; and that the Propagation or Production of the Species is the Effect of the *Vegetative*, not the *Senſitive* Life in Animals, as well as in Plants; and that if there be a Neceſſity of the Concurrence of two different Sexes in *Animals*, at the Begetting or Generating of the Species, the ſame Neceſſity muſt be in *Plants* too: For as a *Cow*, a *Mare*, a *Hen*, a *She-Reptile*, an *Inſect*, &c. cannot produce an Animal without the Male; no more can it be ſuppos'd that a Plant can produce fertile Seed without the Concurrence of the Male Plant, or the Male Parts of the Plant.

Mr. *Ray* ſays, That he will not deny that both Trees and Herbs may produce Fruit, and even come to Maturity, without the Male Seed being ſprinkled upon them. For tho' moſt Birds do not lay Eggs without Congreſs of the Male, yet the Hen often does it without copulating with the Cock; but then theſe Eggs are barren and Wind-Eggs. Juſt ſo, tho' a Female Plant may produce Seed of itſelf, yet that Seed is never fertile. For,

1ſt, As the Work of *Generation* in *Animals* does not proceed from their Animal or Senſitive Life, but from their Vegetative, which being the ſame as in Plants, that Operation muſt be perform'd after the ſame Manner in both: Therefore, as there is a Neceſſity of two different Sexes in Animals, it muſt be ſo too in Plants.

2dly, As paſſive Seminal Matter in Female *Animals* cannot be productive or fertile of itſelf, without being impregnated, animated, or its Particles ſet in Motion and dilated by the active Principles of the Male Seminal Matter; neither can the Female Seed in Plants be render'd fertile, until it be impregnated by the *Farina Fœcundans* from the Male Parts of the Plants.

As to the Flowers of Plants, if they were not aſſiſting to, or if there were not ſome extraordinary Uſe from them in the Perfection of the Seed, they would not be ſo often obſerv'd upon Plants as they are. But ſince there is no Fruit or Seed without a previous Flower; and ſince where the one is obvious, the other is conſpicuous; and ſince one is ſcarce to be obſerved with the naked Eye, neither is the other; this implies a Relation between them, that the one of them is not to be expected without the other.

It is true, there may be Flowers upon a Plant, where the Fruit is ſeldom ſeen, eſpecially in theſe Northern Climates, ſuch as the *Pervinca*, the *Nymphœa alba minima*, and ſeveral others, where the Plant exhauſts the nutritious Juice, in puſhing forth Tendrils, or upon a running Root, which is ſo weakened as not to be able to bring the Fruit to Perfection: But there is no Fruit or Seed to be ſeen, unleſs a Flower has been ſent as a Meſſenger before it, to give Notice of its Approach; tho' it is not always upon the ſame Plant, yet it is ſtill upon ſome other Plant of the ſame Species: for the Flowers are to be ſeen upon diſtinct Plants, different Branches, or different Parts of the Branch from the Fruit, in the *Abies*, *Corylus*, *Nux Juglans*, &c. the *Mercurialis*, *Spinachia*, &c.

But the Fruit never appears, or never begins to increaſe upon theſe Plants, 'till the Flower is ſpent and gone; therefore they muſt ſerve for another Uſe, than to be merely ornamental: for if that were their principal Uſe, they would be always conſpicuous, which they are not, for the moſt part, in apetalous Flowers; and they ſhould always be to be ſeen, and never be hid; which is not ſo in the *Aſarum*, *Hydrocotyle*, &c. where, tho' the Flower is large enough in Proportion to the Fruit, yet it is not to be ſeen unleſs the Leaf be turn'd up, and both Flower and Fruit be narrowly ſearch'd for.

The *Frumenta* and *Gramina* have their ſtaminous Flowers; yet in ſome of them the Flower is ſeldom to be ſeen, unleſs the Spike be ſhaken, and then the *Apices* will appear.

The *Polypodium* and other capillary Plants have regular Flowers, which precede the minute *Capſulæ* or Seed-Veſſels; but neither of them are conſpicuous without a Microſcope.

From theſe Inſtances it appears, that Flowers are not conſtantly a Guard to preſerve the tender Embryo's from the Injuries of the Air; for then the Flowers muſt always have been upon the ſame Pedicle with the Fruit.

Therefore, ſince the Appearance of the Flower is the firſt Step towards the Production of the Seed, whether both be upon the ſame Pedicle or not, it neceſſarily follows, that the one muſt contribute towards the bringing of the other to Perfection.

The Ancients taking Notice, that ſeveral Plants did produce Flowers, and had no Seeds, and that other Plants of the ſame Species, and ſown from the ſame *Seed*, did produce the *Seed* without a previous Flower, they were ready to call the one *Male*, and the other *Female*, without any Notion that the one was aſſiſting to the other; for they look'd upon ſuch Flowers to be only barren; and therefore they call'd thoſe which had Flowers *Female*, and thoſe that produc'd the Fruits *Male* Plants. Thus *Mercurialis* is called *Spicata Fœmina*, and *Teſticulata Mas*. That which produces the Fruit muſt needs be the *Female*, as the Female Animal brings forth the *Fœtus*; and ſo the *Teſticulata* muſt needs be the *Male*, and the *Spicata* the *Female*.

Where-ever the Plants are Annual, theſe, with the Flowers, are ſuch as have the Seed, are always near to each other; but where the Root is Perrennial, and where the Plant is more frequently propagated by the Root than the Seed, the Caſe alters: for there being no need of the Seed to propagate the Plant, there is the leſs need of the Flower to be nearer to the Plant which produces the Seed.

So the *Bryonia* and the *Lupulus* are frequently ſeen to grow, the one to produce the Berry, and the other the *ſquamoſe Fruit*, when the Plants which produce the Male Flowers of the one or the other are at a great Diſtance. And this is ſo far from being an Objection againſt the Neceſſity of two Sexes in Plants, as well as in Animals, that it is an Argument to confirm it; for it ſhews the wonderful Contrivances, in order to preſerve the Species, when the ordinary Means of propagating it by the Seed cannot be ſo conveniently attained.

Theſe, and more that might be produced, being evident Proofs of two Sexes in Plants, as well as in Animals, we ſhall, in the next Place, give ſome Experiments to confirm this in a Negative Way, as has been already done in a Poſitive.

When Plants have been depriv'd of their Male Flowers, or Male Parts in the Flower, they either produc'd no Seed at all, or, if they did, they became abortive, dry'd up, or dwindled away; or, though the Seeds did come to Perfection, they were barren, or did not produce.

Experiment 1ſt: Mr. *Geoffroy* having cut off all the ſtaminous Tufts of Male Flowers from the Top of the Stalk in the *Mayze* or *Turkey Wheat*, as ſoon as they appear'd, and before the Spike loaded with the *Embryo's of the Semen* had put forth from the *Alæ* of the Leaves, ſeveral of theſe *Embryo's* decay'd and dry'd up after they were pretty big; but ſome Grains upon their Pedicles all along the Spike ſwell'd conſiderably, and ſeem'd to be full of the Bud, and were conſequently fertile, while all the others miſcarry'd, and there was not one Spike where the whole Seeds did ripen to the full.

This *Experiment* is a ſufficient Proof of the Uſe of the Male *Flowers* in this Plant; for whatſoever that is which flows from the *Racemi* of theſe *Flowers*, it ſeems it muſt be conducive not only for the Impregnation of the *Seed*, but alſo for the Growth and Impregnation of the *Fruit*.

At preſent we ſhall ſhew, that what Nouriſhment is uſually furniſh'd by the Pedicle to the Embryo's, does not appear to be capable to dilate or expand itſelf, or contribute to the continual Supply of nutritious Particles, unleſs the Embryo's were animated or enliven'd by the Spirit, which ſhould have flow'd from the Male *Flowers*; ſo that they were ſo debilitated and weaken'd, in aſcending from the Body of the Plant towards the Embryo's, before they could arrive at them, that they which otherwiſe might have ſerv'd for the Augmentation and Increaſe of all the Embryo's upon the Spike, could not now do any thing more than contribute to the ripening of a few. And altho' Mr. *Geoffroy* might have imagin'd that theſe few Seeds which came to Perfection were fertile alſo, becauſe they were full of Germs; yet he could not be ſure of that, unleſs he had ſown the ſame Seeds next Seaſon, and try'd whether they would chit or not.

Gardeners who buy *Onion* and *Leek Seed* brought from *Straſburgh*, commonly try the following Experiment: They put a few of the Seeds into a Pot of Water mix'd with Earth, and if they find they begin to ſpring or ſend forth the Seminal Leaf or Fibre of the Root, after a few Days they judge of the Product of it: And notwithſtanding all the Seeds, without this Trial, may ſeem to be productive, being equally firm, hard and ſolid, perhaps not more than one third of them will prove fertile.

And this Barrenneſs may proceed, either becauſe they had never been impregnated by the Male Parts of the Flower, or that they had been too much expos'd to the Air, being ſome time or other too much moiſten'd, and not afterwards been carefully dry'd, or have been kept too long, by which Neglect they loſe their Spirit or Life.

Now, If the Fulneſs, Solidity, and Firmneſs of a Seed is not a ſure Sign of its Fertility, then Mr. *Geoffroy* might have been miſtaken in his Opinion of the Fertility of theſe Seeds in the *Mayze*; ſince he did not make any Trial of it, by committing it to the Ground.

In like manner, as to his ſecond *Experiment* of the *Mercurialis Dioſcoridis*, where he rais'd ſome Plants which had the Fruit, and others which had the ſtamineous Flowers, and remov'd the floriferous Plants before the Flowers were blown, every one of the Seeds upon the fructiferous Plants, except five or ſix, miſcarried; which Seeds were ſo full, that he was perſuaded they were capable of producing new Plants: And the like was found by *Camerarius* in the *Cannabis*. Yet inaſmuch as neither of them try'd the Experiment, by ſowing the ſame Seed the ſecond Year, they could not be ſure but that they might have fail'd in their Expectation.

Mr. *Bobart*, Overſeer of the *Phyſick-Garden* at *Oxford*, many Years ſince, which was before the Doctrine of the different Sexes of Plants was well underſtood, being a Herborizing, found a Plant of the *Lychnis Sylveſtris Simplex*, whoſe Flowers, tho' they had *Stamina*, had no *Apices*: and taking Notice that this was not only in one, but in all the Flowers upon the ſame Plant, he imagin'd it might be a new Species, and therefore mark'd the Plant, and took Care to have it preſerv'd till the Seeds were ripe; and then they being full, hard, and firm, and, to outward Appearance, full of Germ, he ſow'd them in a proper Place in the Garden the next Seaſon; but not a Plant ſprung up from them.

Theſe, and other Inſtances, ſet the Opinion of the different Sexes of Plants upon another Footing than has been received by moſt of our modern Authors: For it imports, that it is not the Nouriſhment of the groſs Subſtance of the Seed itſelf which is hereby meant, nor the Increaſe of the Seed-Veſſel, which is thereby deſign'd; for (as is already obſerv'd) a Hen can lay an Egg, without having before had Congreſs with a Cock; and this, when newly laid, ſhall be of the ſame Bigneſs, Colour, Taſte, and Smell with another Egg which has been cock'd (as they call it) *i. e.* which has been fecundated by the Maſculine Seminal *Materies*: But the Difference will appear, when both are put under the Hen, in order to be hatch'd; for the one ſhall pullulate or chit, and the other ſhall become fœtid and rot.

The Caſe is juſt the ſame with the Seed of a Plant; it may be augmented and increaſed in its Bulk; it may become firm, hard, and ſolid, and have all the Tokens of a perfect Ripeneſs, the Seed-Veſſels may be enlarg'd, and the Pulp or *Parenchyma* of the Fruit may be augmented; and yet the Particles of the Seed may remain crude, indigeſted, and incapable to be explicated and dilated, or ſet in a ſuitable Motion, whereby to protrude the Fibrilla of the Root at one End, and the Seminal Leaves at the other; except it has before received ſome Extraneous Matter or ſome Active Particles from the Male Parts of the Flower, or from the Male Flower itſelf.

In order to confirm the Neceſſity of two Sexes of Plants, as well as in Animals, this familiar Conſideration may be added; That the Fertility or Barrenneſs of any Tree, in the more or leſs fruitful Seaſons, may be known, to ignorant or leſs-curious Perſons, by the Quantity of the Flowers which appear in the Spring-time, and that not only in Trees alone, where the Flower and Fruit are upon one and the ſame Foot-ſtalk, but alſo in ſuch Trees, where the Flowers are upon diſtinct Trees, or ſeparate Places upon the ſame Tree: For it is eaſy to determine, by the *Katkins* or *Juli* upon the *Walnut*, *Filbert*, or *Haſel-trees*, whether ſuch or ſuch Trees will be fertile or barren for the enſuing Seaſon, before any of the Embryo's begin to break, be puſh'd forth, or appear.

Having already treated of the *Male* and *Female Parts* of Flowers, we ſhall next conſider their *Uſe*.

Flowers, in this reſpect, may aptly be divided into that of *Male Flowers*, which (as has been before obſerved) were formerly reputed barren; and the Plants which produced them were alſo called *Female Plants*: Becauſe thoſe Perſons not having any Notion of different Sexes in Plants, they were call'd *Female*, upon Account of their Weakneſs; or if they had any Thought of Sexes in them, it was only alluſive.

The Antients were ignorant of thoſe which are now-a-days call'd *Hermaphrodite Flowers*; and they not having a true Notion of *Sexes* of Plants, could not imagine that the Parts of both Sexes ſhould be in one Flower, upon one and the ſame Foot-ſtalk.

And altho' *Hermaphrodite Animals* bear the leaſt Proportion in the Animal Kingdom, yet *Hermaphrodites* have the greateſt Share in the *Vegetable*; tho' they are not ſo numerous as they have been ſuppos'd to be: For, upon a ſtrict Examination, it will be found, that a great many more Plants have diſtinct Male and Female Flowers, than was formerly believed.

The Neceſſity of different Sexes in Plants having been demonſtrated, and that the Female Seed, tho' it ſhould ripen to the full, cannot be fertile, except it be impregnated by what it receives from the Male Parts of Flowers; we ſhall next explain the Organs of *Generation* in both Sexes.

In the *Animal* Œconomy, there are, beſides thoſe Veſſels that are deſtinated for Nutrition, and the Secretion of the ſeveral Juices in the Body, Spermatick Veſſels, which conſiſt of *Præparantia*, *Differentia*, and *Continentia Semen*. The *Præparantia* in Males are the Blood-veſſels, and the *Teſtes*: The one conveys the Blood; and the other ſeparates the *Semen* from the Blood, and elaborates it.

So likewiſe in *Plants* there are Veſſels that receive the nutritious Particles from the Earth, and convey it to the Extremity of the Plant; ſome of which tend directly to the Leaf, and others to the Flowers.

Thoſe which go to the Foot-ſtalk of the Flower may not improperly be call'd *Spermatick Veſſels*; for 'tis from them that the Seminal Particles in *Male*, *Female*, and *Hermaphrodite Flowers* are ſeparated: Therefore the Foot-ſtalks of the *Hermaphrodite Flowers* are proportionably larger than thoſe either of the *Male* or *Female*; they have a double Office, and contribute ſucceſſively to both.

In thoſe where the *Calyx* becomes the Fruit, the greateſt Supply is furniſh'd to it firſt, and diſtributed in its cortical Parts; as is viſible in the *Roſe*, in which the Foot-ſtalk is ſo far inlarged at firſt, as to be of an equal Bigneſs with the Bud.

After the *Calyx* is thus form'd, the next Diſtribution is to the Inner or Centrical Part of the Flower, which Dr. *Drew* calls *Attire*, and where the *Piſtillum* becomes the Fruit; the *Piſtillum* and *Stylus* are form'd at the ſame time with the *Stamina* and the *Apices*.

The *Stylus* at the very firſt acquires both its due Length and Bigneſs; for the nutritious Particles aſcending in the Center, never ſtop till the *Stylus* is ſtretched out to its full Length; and in ſuch as are furniſh'd with a peculiar *Apex*, that is form'd firſt: The Neck of the *Stylus*, or that Part next to it, is the biggeſt; from thence it gradually decreaſes in its Groſſneſs, till it comes to the *Piſtillum*. This is eaſily perceiv'd by thoſe who will take the Pains to open the Bud of a *Lily*, *Tulip*, &c. before they are half blown.

The *Stamen* is furniſhed next with an extraordinary Supply of the nutritious Particles before the Flower is blown: Theſe, whether fewer or more, are at firſt brought to their proportional Largeneſs, being round and juicy.

The *Apex* is the third which receives this extraordinary Supply of the Nouriſhment; for after that the *Stylus* is form'd, that it may lean to it after the Veſſels of the *Stamen* are extended to their full Length, and ſo form'd that they can convey ſuch an extraordinary Quantity of Particles as may fill up the Capacity of the *Apex*, it is then more inlarg'd than ever after; for if the Flower of a *Lily* be opened before it be blown, the *Apex* will be found to be full as long as the *Stamen*: For as the one half of the *Apex* covers the *Stamen*, fixed to its Center, ſo the other half of it is ſo far extended above the *Stamen*, as the *Stamen* remained uncovered below it, towards the Pedicle or Foot-ſtalk.

The fourth Part of a Flower is the *Petala*, which receives this extraordinary Supply of Nouriſhment before the Blowing: Theſe, upon the Reverſe, are firſt inlarged towards the Pedicle, and are afterwards extended and ſtretch'd forth in Proportion to the Inlargement of the *Attire*: At firſt they are all groſſer and more ſucculent towards the Origin, and gradually become thinner and broader. The *Stamina* of Monopetalous Flowers do, for the moſt part, ariſe partly from the *Petalon* itſelf, and partly from the *Calyx*, eſpecially if the *Stamina* correſpond in Number to the *Petala*, as in the *Hexapetalæ*, or *Polypetalæ Liliaceæ* of *Tournefort*, where every *Stamen* ariſes oppoſite to the Middle of the *Petalon*.

This Obſervation (how and when this more than ordinary Supply of Nouriſhment is carried to the Flowers) eaſily demonſtrates wherein the Analogy of the Organs of *Generation* in *Plants* and *Animals* conſiſts.

In *Animals*, the Seminal Matter is received by proper Veſſels from the ſame Blood from whence the other Secretions fit for the Preſervation of the Animal Œconomy, proceed: So that the Blood in *Animals* being the ſame with the Sap in *Plants*, and both being conveyed after the ſame Manner throughout the ſeveral Bodies; it neceſſarily follows, that the one as well as the other, muſt have proper Veſſels for Secretion of the Seminal Matter.

Let it then be conſider'd, That the Sap or nutritious Juice aſcends in common to the Pedicle of the Flower, as the Blood flows by the *Aorta deſcendens*, and that at the *Calyx* or Bottom of the Flower, ſome Share goes to one Part of it, and ſome to another; as the *Aorta* ſends one Branch to the Spermatick Veſſels, and the Remainder of it goes to perform the other Functions: and as a Part of the Sap is ſeparated by the Pedicle of the Flower, when the Remainder is diſtributed throughout the remaining Parts of the Plant; ſo the *Arteria præparans* goes directly to the *Teſtes* in the Male, and *Ovarium* in the Female: And in Flowers, ſome Veſſels tend directly to the *Calyx* (if it becomes the Fruit) or to the *Perianthium* (if there be any) ſome to the *Petala*, ſome to the *Stamina*, ſome to the *Piſtillum* or *Uterus*, as it is called by *Malpighius*.

Theſe Things being ſeriouſly reflected on, we muſt of Neceſſity conclude,

1. That the ſame due Care is taken to elaborate and prepare the moſt ſubtil and impenetrable Particles of the nutritious Juice in Plants, as of the Blood in Animals.

2. This Subſtance ſo prepared, as it muſt be deſigned for ſome extraordinary Uſe, ſo this Uſe can be no other than that of being the Means of fecundating the Female Seed in Plants, as the other is of the Feminine *Ova* in Animals.

If any one ſhall take a Flower full blown, and pull one of the *Stamina* from the Pedicle, he will find a rough, viſcid Liquor, like to the *Sperma*, which remains here till its moſt ſubtile Parts have either aſcended the *Stamen*; or perhaps, the more groſs Particles might have remain'd there, after the moſt ſubtile had aſcended, before the Flower was blown: This is as plain and demonſtrable as can be in the *Lilies*; and in the *Orange Lily*, and moſt of the *Martagon Lilies*, there is a Contrivance more obvious.

This viſcid Liquor aſcending by parallel Ducts to the *Apex*, there this ſubtile Matter is retain'd till it is farther elaborated by the Evaporations of the more humid and aqueous Particles, by the Heat of the Sun, and then it becomes a moſt ſubtile, fine, impalpable Duſt, which is then ſaid to be ripe, and is call'd the *Farina*.

Dr. *Blair*, after having given the Sentiments of ſeven different Authors upon the Subject, proceeds to give his own, without ſubſcribing to the Sentiment of either the one or the other; and endeavours, by a ſtrict Examination of the Flowers themſelves, to find out which of theſe two Opinions, ſo diametrically oppoſite to each other, are moſt agreeable to Fact.

But before he begins, he lays down this general Maxim, which he takes for granted, That *Nature is uniform in all her Operations, and never recedes from thoſe Rules laid down by the wiſe Diſpoſer of all Things at the Creation, by performing the ſame Thing after two different and contrary Methods*; and thence concludes, That if the *Farina* be a Congeries of Seminal Plants in one Species, it muſt be ſo in all.

If there be an open and direct Paſſage; or tho' it be not ſo direct; yet, if by any indirect Paſſage, by which it can be demonſtrated, that one ſingle Grain of the *Farina* can enter every individual Seed in one Plant, it muſt be ſo in all: But if neither of theſe hold good, and if it can be proved by ocular Inſpection, without the Aſſiſtance of a Microſcope, in thoſe very Plants exemplified by Mr. *Morland*, Mr. *Geoffroy*, and Mr. *Bradley*, that the *Farina* in Subſtance cannot enter the Seminal Veſſel; or if it does, that there is no direct Paſſage for it to enter each particular Seed, after it has ſo got into the *Capſula* or *Siliqua*; then, he hopes, both their Queries, Suppoſitions, and Aſſertions muſt fall.

As for the *Corona Imperialis*, the firſt Example given by Mr. *Morland*, the Flower of which hangs downwards; tho' he does not deny but its *Stylus* may be hollow all the Way, and that it may open at the Extremity; yet, by its Situation, and ſeveral other Circumſtances, it does not ſeem to him to favour this Opinion.

For, 1. As there is a continual Conflux of Particles thro' the Skin in Animal Bodies, it is alſo ſo in Vegetables: This appears by the immediate fading of Flowers, or any other Part of a Plant, after it has been pluck'd off; which proceeds from the Evaporation of the Particles in the little Tubes, without any more ſucceeding in their Place.

He thinks it as reaſonable to ſuppoſe, that theſe Particles flow out by the hollow *Stylus*, as by any other Part, and alſo more ſenſibly there than elſewhere, becauſe of their being concentrated within ſuch narrow Bounds; and that if theſe Particles deſcend by the *Stylus* hanging downwards, the Particles, or rather Grains of the *Farina*, can never aſcend that ſame Way.

2. That if it ſhould be granted, that theſe Grains did aſcend by the *Stylus*; how do they get into the Seminal Veſſel? that being cloſely ſhut up; as will appear to any one who ſhall obſerve it.

3. Whereas Mr. *Morland* ſuppoſes, *That the Rain either waſhes it, or the Wind ſhakes it down the Tube, 'till it reaches the Seminal Veſſel*; Dr. *Blair* obſerves, That the Extremity, which is the upper Part of the *Stylus* in an erect Flower, muſt be the lower in a dependent one; ſo that if either the Rain or Wind have Acceſs to it, it muſt neceſſarily either waſh or drive it away from the Seminal Veſſel, which is now the *Stylus*.

But here the Doctor takes notice of another Contrivance for anſwering that Purpoſe, *i. e.* a Sort of a *Pelvis*, or *Ciſtern*, ſituated at the Origin or Root of each *Petalon*, filled with a viſcous Liquor, which continues there, and never exceeds its Bounds, ſo long as the *Petalon* is in Health: *For ſince the* Apices *are here ſo artfully fix'd, that they turn every Way with the leaſt Wind*, as Mr. *Morland* rightly obſerves, when they burſt, and the *Farina* is driven to and fro, tho' it cannot ſo eaſily enter the Tube, yet it may conveniently be blown up towards the Orifice of the *Petala* ſurrounding the *Stylus*, where it is ſtopped or ſtaid by this Viſcoſity 'till it has perform'd its Office.

To confirm this, he inſtances Mr. *Fairchild*, who, he ſays, being perſuaded that this viſcous Liquor did ſome Way or other contribute towards the fructifying of this Plant; but not underſtanding how it did ſo, he tried the Experiment, by wiping this Liquor off as ſoon as it was depoſited in the *Pelvis*, and the Flower which he ſo ſerved did not bear any Fruit.

And the Way the Doctor accounts for this, is, that the Humidity being removed, the *Farina* is no ſooner blown upwards, than it immediately falls down, without producing any Effect: And that which he takes to be a Confirmation of this, is, that both *Tulips* and *Fritillaria's* have this *Pelvis* or Baſon, yet it is, for the moſt part, dry and empty; becauſe their Flowers being erect, eſpecially the former, they have no ſuch Need of this Liquor to retain the Duſt; for that the Rain having immediate Acceſs to them, may waſh the Duſt towards the Origin of the *Petala*, where it can remain 'till it has perform'd its Office; whereas the Rain having no Acceſs to the inner Surface of the Flower of the *Corona Imperialis*, it is naturally indowed with this Humidity depoſited there by ſeveral excretory Ducts, in order to render it fit for the Purpoſe: And *Malpighius* himſelf takes notice of this Singularity in this Flower, tho' he aſcribes no Uſe to it.

The next Example propoſed by Mr. *Morland*, is the *Yellow Lily*, which, according to his Figure, is repreſented as having *Apices* equally high with the Top of the *Stylus* and the *Petala* over-topping each other; whereas he ſays, that, by the narroweſt Inſpection he ever could make, the Top of the *Apices* (they being then perpendicularly ſituated) reaches no higher than the Neck of the Button upon the Top of the *Stylus*, and that this is before the *Apices* begin to burſt, and ſhed the Duſt; but as ſoon as the Flower begins to open, they depart from the *Stylus*, and force the *Petala* outwards, by a certain Elaſticity, and expand themſelves: This being done, they immediately change their Poſture from a perpendicular to an oblique or horizontal one; nor do they ever pour out their Duſt or *Farina*, 'till they can conveniently drop it upon the Bottom of the Flower, and towards the Root of the *Piſtillum*.

But taking it for granted that it were ſo, the Top of the *Stylus*, (which the Doctor calls the *Button*, in oppoſition to the *Apices Staminum*) he ſays, is ſo compact, and of ſo firm a Subſtance, that it is next to impoſſible that the *Farina* in Subſtance, or in integral Parts, can paſs thro' it.

If the integral Parts, the compleat Grain, the minute *Globuli*, in which the whole Seminal Plant is contained, cannot then enter, the whole Compound muſt be diſſolved, and the minute Seminal Particles in this ſmall Grain of Duſt muſt be diſunited: And if ſo, How ſhall theſe again come to cement, ſo as to make up one continued Body? Or how ſhall this little Body ſo united, penetrate a ſecond Time the Partition-wall betwixt the *Stylus* and *Piſtillum*? And again, How ſhall it find out its Way to its Neſt, in the proper *Embryo* of the Seed?

The Doctor takes notice of the *White Lily*, the *Orange Lily*, the *Martagon Lily*, &c. as Objections to the Opinions of Mr. *Morland*, *Bradley*, &c. and alſo mentions the *Iris*, as a moſt pregnant Inſtance, that the *Farina* cannot ſo much as come at the *Piſtillum*; for having ſix *Petala*, the three *Stamina* with long *Apices* lie hid between the three *Petala* which hang downwards, and three large Expanſions of the *Bifid Stylus*, and the upper Part of the down-hanging *Petalon*: The *Farina* can never reach the Center of the *Stylus*, tho' it were hollow, which it is not, but muſt deſcend along its Outſide, to the Top and Outſide of the Rudiment of the Fruit, there to emit its *Effluvia*.

Theſe and other Inſtances, he concludes, are ſufficient Proof, that the *Farina* cannot enter the *Stylus*, penetrate into the *Piſtillum* or inner Part of the Seminal Veſſel, nor have the leaſt Acceſs to the *Embryo* of the Seed.

As to the Objection, That there is not Paſſage ſufficient to admit the Male Seed into the *Uterus*, or even into the *Ovaries*, it is thus anſwer'd:

If it be conſidered how every Flower, when it is prepared for the Act of receiving the Male Seed, is ſo much under the Influence of the Sun, that the *Petals* open at its Approach, and ſhut up again at its Departure, it very well explains how the *Piſtillum* or Female Parts of *Generation* are relaxed at one Time more than another, *i. e.* that the Female Parts are more relaxed at the opening of the Flower, than when the Flower is ſhut up: For the Flower-Leaves adhering to the Bottom of the *Piſtillum*, muſt conſequently, when they bend back, put every Part of the *Piſtillum* into a different Poſture to that in which it was when the *Petals* were ſhut.

And it is certain, that it is the Preſence of the Sun that ripens the Male Duſt in the *Apices*, and opens the little Caſes in which it is contained, giving them a Springineſs that flings forth that Duſt as ſoon as it is ripe, ſo as to ſcatter it to a conſiderable Diſtance. The Female Parts are at this Time dilated by the opening of the Flower-Leaves, and the *Apices* or *Chives*, concurring at the ſame Time in flinging forth their Male Duſt, anſwer the ſame End in the *Generation of Plants*, that the Act of *Copulation* does among Animals.

Having thus given ſeveral Reaſonings and Arguments uſed by various Authors, who have made it their Study to inveſtigate the Mode of *Generation* of Vegetables, whether the Impregnation of them proceeds from the *Farina Fœcundans*, or Male Duſt, entering the *Uterus* of Plants in Subſtance, or by *Effluvia's*, I ſhall not take upon me to determine the Diſpute; eſpecially ſince Mr. *Boyle* has proved that all *Effluvia's* are ſubtile Particles of Matter; ſo that it matters not how ſmall or minute theſe Particles are, ſince a Body in its firſt State may be ſo minute as to be ſcarcely perceptible.

I ſhall therefore conclude with mentioning a few Experiments of my own, which I communicated to Dr. *Patrick Blair*, which he improv'd as a Proof of his Opinion of *Effluvia*; and Mr. *Bradley* alſo, as a Proof of the *Farina* entering the *Uterus* in Subſtance, and leave the curious Enquirer to determine on that Side of the Queſtion, which Reaſon and Experiment ſhall influence him.

I ſeparated the Male Plants of a Bed of *Spinage* from the Female, and the Conſequence was, that the Seed did ſwell to the uſual Bigneſs; but when ſow'd, it did not grow afterwards: and ſearching into the Seed, I found it wanted the *Punctum Vitæ*.

I ſet twelve *Tulips* by themſelves, about ſix or ſeven Yards from any other; and as ſoon as they blew, I took out the *Stamina* ſo very carefully, that I ſcatter'd none of the Male Duſt; and about two Days afterwards I ſaw Bees working on a Bed of *Tulips*, where I did not take out the *Stamina*; and when they came out, they were loaded with Duſt on their Bodies and Legs, and I ſaw them fly into the *Tulips*, where I had taken out the *Stamina*; and when they came out, I found they had left behind them ſufficient to impregnate theſe Flowers, for they bore good ripe Seeds.

In a Parcel of *Savoys*, which were planted for Seed near white and red *Cabbages*, the Seeds when ſown, produc'd half red, and ſome white *Cabbages*, and ſome *Savoys* with red Ribs, and ſome neither one Sort nor the other, but a Mixture of all Sorts together in one Plant, which I ſuppoſe might happen by the *Effluvia* impregnating the *Uterus* of each other.

In a Letter communicated by *Paul Dudley*, Eſq; to the *Royal Society*, wrote from *New England*, he mentions the interchanging of the Colours of the *Indian Wheat*, if the various Colours are planted in Rows near each other; but if they are planted ſeparately, they conſtantly keep to their own Colour: And this interchanging of Colours has been obſerv'd, when the Diſtance between the Rows of Corn, has been ſeveral Yards; tho' he ſays, if there happens to be a high Board Fence between the different colour'd Corns, the Alteration of Colours is entirely prevented.

Cucumbers and *Melons* do always produce Male and Female Flowers upon different Parts of the ſame Plant: The Male Flower (which appears upon a ſlender Footſtalk, and has a large Style in the Middle, cover'd with an Orange-colour'd *Farina*) is by the Gardeners commonly call'd *Falſe Bloſſoms*, and are ſometimes by unſkilful Perſons pull'd off ſoon after they appear, ſuppoſing that they weaken the Plants if ſuffer'd to remain, which is a very great Miſtake: For in order to try this Experiment, I planted four Holes of Melons in a Place pretty far diſtant from any other; and when the Flowers began to appear, I conſtantly pull'd off all the Male Flowers from Time to Time before they open'd: The Conſequence was, that all the young Fruit dropt off ſoon after they appear'd, and not one ſingle Fruit remain'd to grow to any Size, tho' the Vines were equally ſtrong with thoſe which I had planted in another Place, where I ſuffer'd all the Flowers to remain upon them, from which I had a great Quantity of Fruit.

From theſe, and many other Experiments, it is very plain, that there is a Neceſſity that the *Embryo* of the Female Flower ſhould be impregnated by the *Farina* or Male Duſt, in order to render the Fruit perfect; but how, or in what Manner it is perform'd, is what we can only gueſs at, ſince in the *Generation of Animals*, our greateſt Naturaliſts differ very much in their Opinions, nor can any of them aſcertain any particular Method how it is perform'd: I ſhall therefore conclude with quoting the Words of the Reverend Dr. *Hales*, which are a moſt ingenious Summary of the whole Doctrine of the *Generation of Plants*.

" If I (ſays he) may be allow'd to indulge Conjecture in a Caſe in which the moſt diligent Enquirers are, as yet, after all their laudable Reſearches, advanc'd but little farther than mere Conjecture, I would propoſe it to their Conſideration, whether from the manifeſt Proof we have, that Sulphur ſtrongly attracts Air, a Hint may not be taken, to conſider whether this may not be the primary Uſe of the *Farina Fæcundans*, to attract or unite with itſelf elaſtick or other refin'd active Particles: That this *Farina* abounds with Sulphur, and that a very refin'd Sort, is probable from the ſubtile Oil which Chymiſts obtain from the Chives of *Saffron*: And if this be the Uſe of it, was it poſſible that it could be more aptly plac'd for the Purpoſe on very moveable *Apices* fix'd on the ſlender Points of the *Stamina*, whereby it might eaſily, with the leaſt Breath of Wind, be diſpers'd in the Air, thereby ſurrounding the Plant, as it were, with an Atmoſphere of ſublimed ſulphureous Pounce; for many Trees and Plants abound with it, which uniting with the Air Particles, they may, perhaps, be inſpir'd at ſeveral Parts of the Plant, and eſpecially at the *Piſtillum*, and be thence convey'd to the *Capſula Seminalis*, eſpecially towards Evening and in the Night, when the beautiful *Petala* of the Flowers are clos'd up, and they, with all the other Parts of the Vegetable, are in a ſtrongly imbibing State: And if to theſe united, ſulphureous, and aerial Particles, we ſuppoſe ſome Particles of Light to be join'd, for Sir *Iſaac Newton* has found, that Sulphur attracts Light ſtrongly; then the Reſult of theſe three by far the moſt active Principles in Nature, will be a *Punctum Saliens* to invigorate the Seminal Plant: And thus we are at laſt conducted by the regular Analyſis of Vegetable Nature, to the firſt enlivening Principle of their minuteſt Origin.

Some Perſons have objected to the Theory of the Generation, as here laid down, becauſe they have obſerved ſome female Plants produce Fruit, without having been impregnated by the Male.

It is certain, that the female Plants may produce Fruit, without the Impregnation of the Male; but it is not certain, that this Fruit or Seed will, if ſown, produce another Plant. What has been ſo often related by Travellers and Hiſtorians, of the Neceſſity of the male Palm-Tree being near the female, in order to render it fruitful, hath been fully refuted by Father *Labat*, in his Account of *Africa*, where he has treated of the ſeveral Sorts of *Palms*: He ſays, That he obſerved in *Martinica*, a large Palm-Tree, which grew by the Side of a Convent, which produced Fruit in Plenty, tho' there was no other Palm-Tree growing within two Leagues of this; but he alſo obſerved, that none of theſe Fruit would grow, tho' they had made many Trials of them; ſo that they were obliged to procure ſome Fruit from *Barbary*, in order to propagate theſe Trees. He likewiſe adds, That the Fruit which grew on this female Tree, never ripened ſo perfectly, nor was ſo well taſted, as thoſe which came from Trees which had ſtood near ſome of the Male. Therefore we may conclude, that the Fruit or Seed may be produced by the female Plants of moſt Kinds, without the Aſſiſtance of the male Sperm, which may appear to Sight perfect, and fit to produce other Plants; but if we examine the Seeds, we ſhall find that moſt of them have not the *Germ*, or little Plant incloſed, nor will grow, if they are ſown.

From a repeated Number of Experiments, in ſeparating the male from the female Plants, I have always obſerved, that where it has been done in Time, and with proper Care, ſo as that there could have been none of the *Farina fœcundans* of the male Plant ſcattered on the female; that tho' the female Plants have produced ſometimes fair Seeds to Appearance, yet, when they have been carefully ſown, there has not been one Plant produced from them, except in one Experiment, which I repeated two Years on a female *Briony* Plant, which grew ſingly, having no other Plant of the Kind near it, yet did perfect Seeds, which grew very well the following Seaſon. This Experiment requires a farther Repetition, before any Thing can be aſcertained in relation to the Theory of Generation, there having been ſo many Experiments made on a great Variety of Plants, which have proved the Neceſſity of the *Farina fœcundans* impregnating the female Plants to render them fruitful.

GENISTA JUNCEA; is ſo call'd, of *Genu*, a *Knee*, becauſe it is a very flexible Plant.] *Spaniſh* Broom.

The *Characters* are;

It hath very pliant Branches: The Leaves are plac'd alternately, or in Whorles: The Flowers are of the Pea-bloom Kind, which are ſucceeded by ſmooth Pods, containing ſeveral Kidney-ſhap'd Seeds in each.

The *Species* are;

1. Genista Juncea. *J. B.* The yellow *Spaniſh* Broom.
2. Genista *hortenſis major Luſitanica. Vir. Luſit.* The greater *Portugal* Broom.
3. Genista *Hiſpanica pumila odoratiſſima. Tourn.* Moſt ſweet-ſcented low *Spaniſh* Broom.
4. Genista *Luſitanica, parvo flore luteo. Tourn. Portugal* Broom, with a ſmall yellow Flower.
5. Genista *tinctoria Germanica. C. B. P.* Green-wood, or Dyers-weed, or Wood-waxen.
6. Genista *tinctoria Auſtriaca maxima. Boerh.* Greater *Auſtrian* Dyers-weed, or Wood-waxen.
7. Genista *tinctoria Germanica, foliis anguſtioribus. C. B. P. German* Dyers-weed, or Wood-waxen, with narrow Leaves.
8. Genista *tinctoria fruteſcens, foliis incanis. C. B. P.* Shrubby Dyers-weed, with hoary Leaves.
9. Genista *tinctoria Luſitanica maxima*, Piurna Lusitanorum. *Tourn.* Great *Portugal* Dyers-weed, called *Piurna* by the *Portugueze*.
10. Genista *tinctoria latifolia Lucenſis. Tourn.* Broad-leav'd Dyers-weed of *Luca*.
11. Genista *humilior Pannonica. Tourn.* Lower Broom of *Pannonia*.
12. Genista *ramoſa, foliis hyperici. C. B. P.* Branching Broom, with St. Johnwort-Leaves.
13. Genista *Africana fruteſcens, ruſci nervoſis foliis. Oldenl.* Shrubby *African* Broom, with ribbed Butchers-Broom Leaves.
14. Genista *Africana fruteſcens, ruſci anguſtis foliis. Oldenl.* Shrubby *African* Broom, with narrow Butchers-Broom Leaves.
15. Genista *Africana arboreſcens, argenteâ languine pubeſcens. Oldenl.* Tree-like *African* Broom, covered with a ſilvery Down.
16. Genista *Africana fruteſcens ſpicata purpurea, foliis anguſtiſſimis. Oldenl.* Purple-ſpiked ſhrubby *African* Broom, with very narrow Leaves.
17. Genista *Africana fruteſcens ſpicata, laricis foliis. Oldenl.* Spiked ſhrubby *African* Broom, with larch-tree Leaves.
18. Genista *Africana fruteſcens capitata, laricis foliis. Oldenl.* Headed *African* ſhrubby Broom, with larch tree Leaves.
19. Genista *Africana fruteſcens, capitulis lanuginoſis, laricis breviſſimo folio. Oldenl.* Shrubby *African* Broom, with woolly Heads, and a very ſhort larch-tree Leaf.
20. Genista *Africana fruteſcens, laricis incanis foliis. Oldenl.* Shrubby *African* Broom, with hoary Larch-Tree Leaves.

The firſt of theſe Plants is very common in the Nurſeries near *London*, and is generally ſold by the Gardeners amongſt other flowering Shrubs for Wilderneſs Quarters; where, by its long Continuance in Flower, together with its Sweetneſs, it affords an equal Pleaſure with moſt other flowering Shrubs.

This Plant is eaſily propagated by ſowing the Seeds (which are annually produc'd in great Quantities upon the old Plants) in the Spring of the Year, upon a warm dry Soil, and in an open Expoſure, obſerving not to cover the Seeds too thick with Earth, (a Quarter of an Inch will be ſufficient); nor ſhould you water the Ground until the Plants come up, which will be in about ſix Weeks after ſowing, for too much Moiſture rots the Seeds: During the Summer-Time you muſt diligently clear the young Plants from Weeds, which, if ſuffer'd to remain, would in a ſhort Time over-run and deſtroy the Plants. In this Place the Plants ſhould remain until the *March* following; at which Time you ſhould prepare a freſh Spot of Ground, in proportion to the Quantity of Plants you have to tranſplant: The Ground being well dug and levell'd, you ſhould mark out the Rows ſtrait by a Line at three Feet Diſtance from each other: Then take up your Plants, being careful not to break their Roots, which would be very injurious to them, and ſet them a Foot aſunder in the Rows, cloſing the Earth to them with your Feet; and if the Weather ſhould be very dry, you may give them a little Water, laying on a little Mulch firſt upon the Surface of the Ground near their Stems: This watering may be repeated once a Week, if the Seaſon ſhould prove dry, until they have taken freſh Root, which will be by the Beginning of *May*, after which Time they will be in no Danger of miſcarrying: You muſt obſerve alſo to keep the Ground clear from Weeds; and in *February* or *March*, you ſhould dig up the Ground between the Rows to looſen the Earth, that the Roots of the Plants may the eaſier inſinuate themſelves and ſpread on each Side, otherwiſe they will be ſubject to have downright Tap-roots, which will render them very difficult to tranſplant. In this Nurſery the Plants may remain two Years, by which Time they will be full large enough to be removed to the Places where they are deſign'd to remain for Flowering: Nor ſhould they be ſuffer'd to continue above three Years at moſt in the Nurſery, for after that Time it will be very dangerous to remove them, they being ſome of the worſt Kind of Shrubs to tranſplant, when grown large, that I know amongſt all the Variety of flowering Trees. The beſt Time for tranſplanting them is, as I ſaid before, towards the latter End of *March*, obſerving to do it in a perfect mild Seaſon, and when the Wind is South, or Weſterly; for if the Wind blows from the North or Eaſt at this Seaſon, it either brings froſty Nights or cold drying Winds, both of which are equally hurtful to theſe Plants when firſt remov'd. You ſhould obſerve to lay ſome Mulch round their Stems, to prevent the Sun and Wind from penetrating the Earth and drying their Fibres; as alſo to water them in dry Weather, as was before directed, until they have taken Root, after which Time they will be in no Danger.

This, altho' a Native of *Spain*, and the warm Parts of *Europe*, yet is become ſo hardy as to reſiſt the Cold of our Climate in the open Air, and will grow to the Height of twelve or fourteen Feet, and produce annually large Quantities of ſweet yellow Flowers, and perfect its Seeds; which if ſuffer'd to fall to the Ground, will remain, and come up the ſucceeding Spring, whereby you may be eaſily furniſh'd with young Plants without much Trouble, provided the Ground be not dug, nor the Seeds bury'd too deep to grow.

The *Portugal* Sort is at preſent very rare in *England*, and only to be found in ſome curious Collections of Plants: This is not ſo hardy as the former, and requires to be ſhelter'd during the Winter, tho' I am apt to believe it will ſtand abroad when grown woody, if planted in a light dry Soil and a warm Situation. This Plant flowers with us, but hath not as yet produc'd any Fruit in *England* that I have heard.

The third Sort is not very common in the *Engliſh* Gardens; this is of much lower Growth than the common *Spaniſh* Broom, and the Flowers have a more agreeable Scent; but being equally hardy with the common Sort, may be eaſily propagated in *England*, and will be a very ornamental Shrub, to plant in Front of the *Spaniſh* Broom; will fill up the Bottom, and hide the naked Stems of thoſe Plants; ſo are very proper to form Clumps of theſe Trees, which will have an agreeable Effect, when properly placed in Gardens.

The fourth Sort is alſo uncommon at preſent in *England*, but the Seeds may be eaſily procured from *Portugal*. This Sort hath ſmall Flowers, which have little Scent, ſo is not ſo valuable as the former Sort, nor is it quite ſo hardy. This will live in the open Air in moderate Winters, but in very hard Froſt they will be in danger of being deſtroyed, where they are not ſheltered; ſo that ſome of theſe Plants ſhould be kept in Pots, that they may be removed into the Green-houſe in Winter, to preſerve the Kind.

The fifth Sort grows wild in uncultivated Places in moſt Parts of *England*, and is gathered for the Uſe of the Dyers; this, as alſo the common Broom, are extremely bitter; ſo that, whenever they are eaten by the Cows, it gives a very bitter Taſte to the Cheeſe and Butter which is made of their Milk.

The ſixth Sort grows wild in *Auſtria*, from whence the learned Dr. *Boerhaave* procured the Seeds, who has ſince diſtributed it to ſeveral curious Perſons in *England*.

The ſeventh Sort grows wild in *Germany*, as alſo in *France* and *Flanders*, but is not very common in *England*. Theſe three Sorts are of humble Growth, ſeldom riſing above two Feet high; but as they make a fine Appearance when they are in Flower, ſo they merit a Place in every good Garden; where, if they are diſpoſed in Clumps, in the Middle whereof the common *Spaniſh* Broom muſt be planted, and round that the firſt Sort here mentioned, with theſe three Sorts round the Outſide, the whole Clump will appear like one great Buſh of yellow Flowers; for as they all produce their Flowers at the ſame Seaſon, which continue a conſiderable Time, ſo they make an agreeable Variety in large Gardens, and require very little Care, excepting to clear them from large over-bearing Weeds, after they have taken Root.

The eighth and ninth Sorts riſe to a greater Height than either of the former, but are ſomewhat tenderer, being Natives of warmer Countries; ſo ſome of theſe ſhould be kept in Pots, that they may be removed into Shelter in Winter; for tho' they will endure the Cold of our ordinary Winters in the open Air, if planted in a warm Situation, yet they are often deſtroyed in very hard Froſts; ſo that where ſome of them are not protected, the Sorts may be loſt.

The tenth and eleventh Sorts ſeldom riſe above two Feet high, ſo are proper to mix with the fifth ſixth and ſeventh Sorts, to form Clumps, *&c.* Theſe are ſomewhat tender while young, ſo ſhould be kept in Pots and ſheltered for a Year or two while young; but afterward they will live in the open Air very well, provided they are planted in a warm Situation.

The twelfth Sort is a low ſpreading Plant, ſeldom riſing to the Height of two Feet, but ſpreads its Branches pretty far on every Side. The Flowers of this Kind are ſmall, and being produced thinly at the Extremity of the Branches, does not make ſo good an Appearance, as either of the former Sorts. This is very hardy, ſo will endure the Cold of our Climate extremely well.

All theſe Sorts are propagated by Seeds, which ſhould be ſown on a Bed of light Earth, in an open Situation, toward the End of *March*; for if they are ſown too early, and the Spring ſhould prove cold or wet, the Seeds generally periſh in the Ground. When the Plants begin to appear, they ſhould be carefully weeded, and in very dry Weather they ſhould be gently refreſhed with Water, which will very much promote their Growth: during the Summer Seaſon, they muſt be conſtantly kept clear from Weeds, which is the only Culture they will require. In this Bed the Plants may remain until the following Spring, when they ſhould be tranſplanted juſt before they begin to ſhoot; ſo that you ſhould prepare a Spot of freſh Ground, which ſhould be carefully dug and cleanſed from the Roots of bad Weeds; then you muſt take up the Plants with great Care, for they generally ſhoot long Roots pretty deep in the Ground; which, if they are too much torn, will endanger the Plants. Theſe muſt not lie long out of the Ground, for at this Seaſon their Roots will dry very ſoon; therefore they ſhould be immediately planted, and the Surface of the Ground muſt be covered with Mulch, to prevent the Sun and Wind from entering the Ground, and drying the Roots of the Plants; then they ſhould be well watered, and if the Spring ſhould prove dry, it will be proper to repeat the Waterings two or three times in a Week, until the Plants are well rooted. The Diſtance which ſhould be allowed to theſe Plants, for thoſe of the larger Growth, is three Feet Row from Row, and eighteen Inches aſunder in the Rows; but for thoſe of ſmall Growth, two Feet Diſtance Row from Row, and one Foot aſunder in the Rows, will be ſufficient. In this Nurſery the Plants may remain two Years; during which Time they ſhould be conſtantly kept clear from Weeds, and the Ground between them muſt be carefully dug every Spring, to prevent their Roots from running out too far; for as they ſend forth long ſlender Tap-roots, ſo, if theſe are not cut to force out Fibres near the Stem of the Plants, they will be in Danger of ſuffering when they are tranſplanted; for which Reaſon they ſhould not remain in the Nurſery longer than two Years, becauſe theſe Plants cannot be removed, when they are older, with any Safety. The beſt Seaſon to tranſplant theſe Plants, is toward the End of *March*, or the Beginning of *April*, juſt before they begin to ſhoot; when they muſt be carefully taken up, as was before directed, and planted again immediately, covering the Surface of the Ground with Mulch, and obſerving to water them in dry Weather, until they have taken Root again; after which Time they will require no farther Care, but to keep them clear from great over-bearing Weeds, which, if permitted to grow amongſt them, would greatly weaken, if not abſolutely deſtroy them. Theſe Plants moſt of them flower in *June*, *July*, and *Auguſt*, and their Seeds ripen in *September*.

The thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth, nineteenth, and twentieth Sorts, are Natives of the Country about the *Cape* of *Good Hope*, ſo are tenderer than either of the former Sorts; theſe are preſerved in Pots, and removed into the Green-houſe in Winter; for they cannot endure the Cold of our Winters in the open Air: but they ſhould have a great Share of freſh Air in mild Weather; ſo, if they are placed in an airy Glaſs-caſe, amongſt *Ficoides*, and other hardy exotic Plants, which require a large Share of Air in Winter, as alſo as much Sun as poſſible; they will thrive bettter than when they are placed amongſt Orange-trees in a common Green-houſe, and will flower much better. In Summer theſe Plants muſt be placed abroad in a warm Situation, where they may be defended from ſtrong Winds; and in dry Weather they muſt be frequently watered, which will encourage them to flower freely, and cauſe them to produce good Seeds; for want of which Care the Flowers often fall off, and are not ſucceeded by Pods.

Theſe Plants are propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark; and when the Plants begin to appear, they muſt be kept clear from Weeds, and frequently refreſhed with Water: the Glaſſes of the Hot-bed muſt alſo be raiſed every Day, to admit freſh Air to the Plants, otherwiſe they will draw up very weak; for as theſe Plants are not very tender, ſo they muſt be inured to bear the open Air as ſoon as the Seaſon proves favourable; toward the latter End of *May*, the Pots ſhould be removed out of the Hot-bed, and placed for a little time in a Glaſs-caſe, where they may have a greater Share of Air; and the Middle of *June*, they ſhould be placed in the open Air in a ſheltered Situation, where they may remain till *October*; when they muſt be removed into the Glaſs-caſe again, where they ſhould be placed on Shelves, to enjoy the Advantage of Air and Sun; and during the Winter they muſt be frequently refreſhed with Water, but it ſhould be given in ſmall Quantities at this Seaſon, eſpecially while the Plants are young. The following Spring, theſe Plants ſhould be ſhaken out of the Pots, and carefully parted, planting each of them into a ſeparate ſmall Pot, filled with light freſh Earth, and plunged into a very moderate Hot-bed, which will facilitate their taking Root; but the Glaſſes of the Hot-bed ſhould be covered with Mats every Day, to ſcreen the Plants from the Sun, until they are rooted; after which time they ſhould have a large Share of freſh Air, and muſt be frequently watered. In *May* they muſt be inured to bear the open Air by Degrees, into which they ſhould be removed the Beginning of *June*, and placed in a warm Situation. With this Management theſe Plants will thrive very well, and in two Years after will begin to produce their Flowers, when they will make an agreeable Diverſity amongſt other exotic Plants.

GENISTA SPINOSA; the Furz, Whins, or Gorſe.

The *Characters* are;

The whole Plant is very thorny: The Flowers (which are of the Pea-bloom Kind) are diſpos'd in ſhort thick Spikes, which are ſucceeded by ſhort compreſs'd Pods, in each of which are contain'd three or four Kidney-ſhap'd Seeds.

The *Species* are;

1. GENISTA SPINOSA *vulgaris. Ger. Emac.* The Common Furz, Whins, or Gorſe.
2. GENISTA SPINOSA *minor. Park. Theat.* The leſſer Furz.
3. GENISTA *minor Aſphalathoides, vel Geniſta Spinoſa Anglica. C. B. P.* Needle-Furz, or Petty-Whin.

Theſe three Plants do all of them grow wild on the Heaths and up-land Commons in divers Parts of *England*, and are ſeldom planted in Gardens: but if they are rightly diſpos'd in Clumps or Wilderneſs Quarters, and train'd up to regular Heads, they will make a very agreeable Diverſity amongſt other flowering Shrubs; and for their long continuance in Flower, do merit a Place in every ſuch Plantation.

This firſt of theſe Plants is ſometimes us'd to make Hedges, for which Purpoſe it will do very well for a few Years, provided it be kept cloſe at firſt, and the Ground underneath always kept clear from Weeds: And it ſhould always be obſerv'd, never to cut theſe Hedges in very dry Weather, nor too early in the Spring, or too late in Autumn; for if it ſhould prove cold froſty Weather, or drying eaſterly Winds happen ſoon after it be cut, they will render the Hedge very unſightly for a long time, and often deſtroy many of the Plants, whereby the Form and Beauty of the Hedge will be entirely loſt; and if you cut it too cloſe into the old Wood, it rarely ever breaks out again: So that if the Hedge ſhould have grown beyond the Bounds you intended it, the better way will be, to cut it quite down to the Ground, and let it riſe again from the Roots. See more of this under the Article of *Hedges*.

The ſecond Sort never riſes ſo high as the firſt, and is therefore proper to intermix with Shrubs of ſhorter growth; but will do for all the Purpoſes of the firſt, and is equally as common in moſt Parts of *England*.

The third Sort ſeldom riſes above three Feet high; nor will it ſupport itſelf while young, and therefore ſhould be faſten'd to a Stake, training the Stem upright, and forming it into a regular Head; and after two or three Years being thus manag'd, it will ſupport itſelf, and make a very handſome Appearance. This Plant produces its Flowers in *April*, and continues them through *May*, during which Seaſon it affords a very agreeable Proſpect. The Seeds ripen in *Auguſt*; and, if ſuffer'd to ſcatter, they will come up the ſucceeding Spring.

Theſe Plants may be all propagated by ſowing their Seeds in *March*; which, if intended for a Hedge, ſhould be ſown in the Place where they are to remain; but if for Standards to plant in Wilderneſſes, they ſhould be ſown thin upon a Bed of light Earth, in an open Situation; and when the Plants come up, you ſhould carefully clear them from Weeds; and where they are too cloſe to each other, they ſhould be pull'd out, leaving 'em at leaſt ſix Inches diſtant from each other: In theſe Beds they ſhould remain until the *Spring* following, at which time they ſhould be remov'd either into the Places where they are to continue, or elſe into a Nurſery, as was directed for the *Spaniſh Broom*, obſerving the ſame Method and Seaſon for this Work as was there directed, to which this Plant exactly agrees in Culture, and is equally as difficult to tranſplant when grown old; therefore, to avoid Repetition, I ſhall refer the Reader to that Article for farther Inſtructions.

GENTIANA [takes its Name from *Gentius* a King of *Illyria*, who firſt diſcover'd the Virtues of this Plant] Gentian, or Fell-wort.

The *Characters* are;

The Leaves grow by Pairs oppoſite to each other: The Cup of the Flower conſiſts of one membranous Leaf: The Flower conſiſts of one Leaf, and is ſhap'd like a Cup, being cut into four, five, or more Segments: It is ſucceeded by a membranous Oval-ſhap'd Fruit, ending in a ſharp Point, opening lengthwiſe into two Parts, and containing many flat, roundiſh Seeds, which are border'd with a leafy Rim.

The *Species* are;

1. Gentiana *major lutea.* *C. B. P.* The great *Gentian*, with yellow Flowers.
2. Gentiana *aſclepiadis folio.* *C. B. P.* *Gentian*, with a Swallow-wort Leaf.
3. Gentiana *Alpina, flore magno.* *J. B.* Large flower'd *Gentian* of the Alps, *commonly call'd* Gentianella.
4. Gentiana *cruciata.* *C. B. P.* Croſs-wort *Gentian.*
5. Gentiana *anguſtifolia autumnalis major.* *C. B. P.* Great Autumnal *Gentian*, *or* Calathian Violet.

There are ſeveral other Sorts of *Gentian*, ſome of which are Natives of *England*, and others are Inhabitants of the *Alps*, and other cold mountainous Parts of *Europe*: But as they are Plants which are rarely tam'd, ſo as to thrive well in Gardens, eſpecially near *London*, I ſhall paſs them over in this Place, and proceed to the Culture of thoſe here inſerted, all of which are worthy of a Place in every good Garden.

The firſt Sort, which is the true *Gentian*, whoſe Root is uſed in Medicine, is an Inhabitant of the Mountains near *Geneva*, and the Paſtures of the *Alps* and *Pyrenees*: This Plant is propagated by Seeds, which ſhould be ſown ſoon after they are ripe; for if it be kept long out of the Ground, it rarely grows. The beſt Method is, to ſow the Seeds in a large Pot fill'd with light undung'd Earth, covering them about a quarter of an Inch thick with the ſame light Earth; then place the Pots in the Shade, where they may remain until *November*, at which time you may remove them into a Place where they may have the Morning Sun; in this Situation they may remain 'till *March* following, by which Time the young Plants will appear above-ground: You muſt then remove the Pots again into a ſhady Place, where they ſhould remain all the Summer Seaſon, obſerving to clear them from Weeds, as alſo to water them in dry Weather, which will greatly promote their Growth. The Spring following they will be fit to tranſplant; at which time you ſhould prepare a ſhady moiſt Border, that ſhould be well dug and looſen'd; then ſhake the Earth out of the Pots, by which means you will the more readily take them out without hurting their Roots. The Diſtance they ſhould be allow'd, if deſign'd to remain for good, muſt be fourteen Inches ſquare: But if they are intended to be removed again, four or ſix Inches will be ſufficient. In planting them, you muſt obſerve to make deep Holes, ſo that the Roots, which generally grow long, may be placed full as deep as they are in Length, that no Part may appear above-ground; nor ſhould they be bent at the Bottom, which would check their downright Growth, and greatly injure them. The beſt Seaſon to tranſplant them is in the Beginning of *March*, juſt as they begin to ſhoot.

In about five or ſix Years time, if the Plants thrive well, and are not diſturb'd, they will begin to flower, and will produce good Seeds; ſo that it will not be difficult to have them in great Plenty: But as it is hardly worth cultivating for Medicinal Uſe, it being generally imported hither at a very moderate Price; ſo the Beauty thereof is not ſuch as would recommend the having it in great Quantities; tho' a few of 'em will do very well to make a Variety.

The ſecond and fourth Sorts are at preſent very uncommon in *England*, and only to be found in ſome curious Gardens; theſe are both of them very pretty Ornaments to a Garden: They are propagated by parting their Roots either in Spring or Autumn, and require a pretty ſtrong Soil, and a ſhady Situation.

The third Sort was formerly more common in the Gardens near *London* than it is at preſent, but in ſome old Country Gardens it is ſtill frequently to be met with: This is a very beautiful Plant, and well worth propagating: It is increaſed by parting the Roots early in the Spring; for if it be left undone 'till *March*, the Flower-buds will begin to appear; after which time, if you remove them, it will greatly weaken their flowering. Theſe Plants require a ſtrong, moiſt, cool Soil, and ſhould be planted where they may have only the Morning Sun; for if they are too much expos'd to Heat, they are very ſubject to decay; nor do they care to be often tranſplanted, which will alſo make them poor and weak: And I am apt to believe that this has occaſioned their preſent Scarcity near *London*, where People are too apt to part and divide Plants often, in order to increaſe them, and thereby frequently deſtroy their whole Stock.

The fifth Sort grows wild in divers Parts of the North, as in *Yorkſhire*, *Cumberland*, and *Northumberland*, and is equal to any of the above-mentioned Kinds for Beauty, but is rarely to be found near *London*. The Roots of this Plant may be brought from the Places of its natural Growth, and planted in a cool, moiſt, undung'd Soil, where it will grow, provided it be not under the Drip of Trees, which this Plant by no means cares for; nor ſhould it be often removed, but ſuffer'd to remain, (as was ſaid above) by which means it will thrive, and produce beautiful Flowers.

GENTIANELLA. *Vide* Gentiana.

GERANIUM [takes its Name from Γέρανος, Gr. a *Crane* or *Stork*, becauſe its Fruit reſembles the Bill of a Crane] Crane's-bill.

The *Characters* are;

The Leaves are for the moſt part conjugate: The Cup of the Flower conſiſts of one Leaf, which is divided into five Parts, and expanded in form of a Star: The Flowers of the European *Kinds conſiſt of five Leaves; and thoſe of the* African *Sorts (for the moſt part) of four, ſomewhat reſembling a creſted or lipp'd Flower, with ten* Stamina *ſurrounding the Ovary: The Fruit is of a pentagonal Figure, with a long Beak, containing at the Baſe five*

five Seed-veſſels, in each of which is contained one tail'd Seed, which, when ripe, is caſt forth by the twiſting of the Beak.

The *Species* are;

1. GERANIUM *batrachioides, Gratia Dei Germanorum. C. B. P.* Crane's-bill, with a Crowfoot Leaf, and large blue Flowers.

2. GERANIUM *batrachioides, Gratia Dei Germanorum, flore albo. Boerh. Ind.* Crowfoot-leaf'd Crane's-bill, with a white Flower.

3. GERANIUM *batrachioides, Gratia Dei Germanorum, flore variegato. C. B. P.* Crowfoot-leaf'd Crane's-bill, with a ſtriped Flower.

4. GERANIUM *batrachioides, longius radicatum, odoratum. J. B.* Long-rooted ſweet-ſmelling Crane's-bill, with a Crowfoot Leaf.

5. GERANIUM *ſanguineum, maximo flore. H. Ox.* Bloody Crane's-bill, with a large Flower.

6. GERANIUM *ſanguineum, cauliculis erectis, folio obſcure virenti, floribus minoribus. H. L.* Bloody Crane's-bill, with upright Stalks, dark-green Leaves, and ſmall Flowers.

7. GERANIUM *hæmatodes, foliis majoribus, pallidioribus, altius inciſis. Raii Syn.* Bloody Crane's-bill, with larger, paler, and more deeply-divided Leaves.

8. GERANIUM *hæmatodes Lancaſtrenſe, flore eleganter ſtriato. Raii Hiſt.* Bloody Crane's-bill, with a variegated Flower.

9. GERANIUM 5. *nodoſum Plateau. Cluſ. Hiſt.* Knotty Crane's-bill.

10. GERANIUM *phæum ſive fuſcum, petalis reflexis, folio non maculoſo. H. L.* Brown Crane's-bill, with reflex'd Petals, and Leaves not ſpotted.

11. GERANIUM *phæum ſive fuſcum, petalis rectis ſeu planis, folio maculato. H. L.* Brown Crane's-bill, with plain Petals, and ſpotted Leaves.

12. GERANIUM *Romanum, verſicolor ſive ſtriatum. Park. Par.* Roman Crane's-bill, with ſtriped Flowers.

13. GERANIUM *Alpinum, coriandri folio, longius radicatum, flore purpureo majore. Michel.* Long-rooted Crane's-bill of the Alps, with a Coriander-leaf, and a large purple Flower.

14. GERANIUM *batrachioides montanum noſtras. Ger.* Mountain Crane's-bill, with a Crowfoot Leaf.

15. GERANIUM *Orientale columbinum, flore maximo, Aſphodeli radice. T. Cor.* Oriental Dove's-foot Crane's-bill, with an Aſphodel Root, and a large Flower.

16. GERANIUM *cicutæ folio, Moſchatum. C. B. P.* Muſked Crane's-bill of Muſcovy.

17. GERANIUM *latifolium annuum, ceruleo flore, acu longiſſima. H. Ox.* Broad-leaf'd annual Crane's-bill, with a blue Flower, and a very long Beak.

18. GERANIUM *myrrhinum tenuifolium, flore amplo purpureo. Bar. Obſ.* Fine cut-leaf'd Crane's-bill; with an ample purple Flower.

19. GERANIUM *Africanum arboreſcens, ibiſci folio rotundo, carlinæ odore. H. L.* African-tree Crane's-bill, with a round Marſhmallow Leaf, and a Smell of the *Carline Thiſtle*.

20. GERANIUM *Africanum arboreſcens, ibiſci folio anguloſo, floribus amplis purpureis. Phil. Tranſ.* 388. African-Tree Crane's-bill, with an angular Marſhmallow Leaf, and large purple Flowers.

21. GERANIUM *Africanum arboreſcens, alchimillæ hirſuto folio, floribus rubicundis. Com. Præl.* African-Tree Crane's-bill, with a hairy Lady's-mantle Leaf, and red Flowers.

22. GERANIUM *Africanum arboreſcens, malvæ folio plano lucido, flore elegantiſſime kermeſino. Di van Leur. Boerh. Ind.* African-Tree Crane's-bill, with a plain, ſhining Mallow Leaf, and an elegant ſcarlet Flower.

23. GERANIUM *Africanum muteſcens, malvæ folio odorato laciniato. H. L.* African ſhrubby Crane's-bill, with a jagged, ſweet-ſmelling Mallow Leaf.

24. GERANIUM *Africanum fruteſcens, malvæ folio laciniato, odorato inſtar meliſſæ, flore purpuraſcente. Boerh. Ind.* African ſhrubby Crane's-bill, with a jagged Mallow Leaf ſmelling like Balm, and a purpliſh-colour'd Flower.

25. GERANIUM *Africanum arboreſcens, malvæ folio mucronato, petalis florum inferioribus vix conſpicuis. Phil. Tranſ.* African-Tree Crane's-bill, with a pointed Mallow Leaf, and the under Petals of the Flower ſcarce diſcernable.

26. GERANIUM *Africanum fruteſcens, folio craſſo & glauco, Acetoſæ ſapore. Com. Præl.* African ſhrubby Crane's-bill, with a thick glaucous Leaf, and an acid Taſte like *Sorrel*.

27. GERANIUM *Africanum fruteſcens, chelidonii folio, petalis florum anguſtis albidis, carnoſo caudiſæ. Phil. Tranſ. Geranium Africanum, folio alceæ, flore albo. Boerh. Ind. alt.* African ſhrubby Crane's-bill, with a Celandine Leaf, the Petals of the Flower white and narrow, and a fleſhy Stalk.

28. GERANIUM *Africanum noctu olens, tuberoſum & nodoſum, aquilegiæ foliis. H. L.* African Crane's-bill, ſmelling ſweet in the Night, with knotty, tuberoſe Stalks and Leaves like *Columbine*.

29. GERANIUM *Africanum, folio alceæ, flore coccineo fulgidiſſimo. Boerh. Ind. alt. Geranium Surianenſe, chelidonii folio, flore coccineo, petalis inæqualibus. Hort. Piſſ.* African Crane's-bill, with a vervain Mallow Leaf, and a deep-ſcarlet Flower.

30. GERANIUM *Africanum arboreſcens, alchimillæ folio hirſuto, elegantiſſime variegato, floribus rubicundis. Boerh. Ind. alt.* African-tree Crane's-bill, with a hairy Ladies-mantle Leaf elegantly ſtriped, and red Flowers, *commonly call'd the* Striped Geranium.

31. GERANIUM *Africanum, foliis inferioribus aſari, ſuperioribus ſtaphidiſagriæ, maculatis, ſplendentibus, & acetoſæ ſapore. Com. Præl.* African Crane's-bill, with the under Leaves like Aſarabacca, and the upper Leaves like Staveſacre, ſhining, ſpotted, and taſting like *Sorrel*.

32. GERANIUM *Africanum, alchimillæ hirſuto folio, floribus albidis. H. L.* African Crane's-bill, with a hairy Ladies-mantle Leaf, and whitiſh Flowers.

33. GERANIUM *Africanum, folio malvæ craſſo molli odoratiſſimo, floſculo pentapetalo albo. Boerh. Ind. alt.* African Crane's-bill, with a thick, ſoft, ſweet-ſmelling Mallow Leaf, and a ſmall white Flower conſiſting of five Leaves.

34. GERANIUM *Americananum, noctu olens, radice tuberoſa, triſte. Corn. H. Ox.* American tuberoſe-rooted Crane's-bill, ſmelling ſweet in the Night.

35. GERANIUM *Africanum tuberoſum, anemones folio, incarnato flore. Par. Bat.* Tuberoſe-rooted African Crane's-bill, with an Anemony Leaf, and a pale Fleſh-coloured Flower.

36. GERANIUM *Æthiopicum, noctu olens, radice tuberoſa, foliis myrrhidis anguſtioribus. Breyn Cent.* Night ſweet-ſmelling Ethiopian Crane's-bill, with a tuberoſe Root, and narrow Cicely Leaves.

37. GERANIUM *Africanum, noctu olens, folio vitis hirſuto, tuberoſum. H. A.* Night ſweet-ſmelling African Crane's-bill, with a hairy Vine Leaf, and a tuberoſe Root.

38. GERANIUM *Africanum, folio coriandri, floribus incarnatis, minus. H. L.* African Crane's-bill, with a Coriander Leaf, and a leſſer Fleſh-coloured Flower.

39. GERANIUM *Africanum, uvæ criſpæ folio, floribus exiguis rubellis. H. L.* African Crane's-bill, with a Gooſeberry Leaf, and ſmall reddiſh Flowers.

40. GERANIUM *Africanum, betonicæ folio, procumbens, floribus parvis eleganter variegatis. Pluk. Alm.* African trailing Crane's-bill, with a Betony Leaf, and ſmall, beautiful, ſtriped Flowers.

The fifteen firſt mentioned Sorts are abiding Plants; the Leaves of ſome of them do decay in Winter; but their Roots remaining, ſhoot again early in the Spring: Some of theſe Sorts are common in ſeveral Parts of *England*, yet they deſerve a Place in every good Garden, where, if they are rightly diſpos'd, they will have a good Effect, by adding to the Variety; and as they are very hardy Plants, and require but little Care in their Culture, growing in almoſt any Soil or Situation, ſo they are very proper for large Gardens, to be planted in wide Borders, or by the Sides of Wilderneſſes, and other ſhady Walks, where few other Plants will thrive; and theſe continuing in Flower moſt Part of the Summer, do greatly add to the Beauty of ſuch Places.

Theſe are all increaſed by parting their Roots; the beſt Seaſon for which is in *October*, that they may take Root before the hard Froſts begin; or elſe in *February*, that they may get Strength before the great Heat and Drought comes on, which would occaſion their Flowers to be ſmall, and but few in Number. Theſe Roots may remain two or three Years unremoved, according as you find them increaſe and ſpread; for ſome Sorts will not ſpread ſo far in three Years, as others will do in one: ſo that if the ſpreading Kinds are ſuffered to grow undiſturb'd for two or three Years, they will ſpread the whole Width of the Border where they are planted; ſo that if they are not tranſplanted often, their Roots ſhould be cut round every Year, to keep them within Compaſs.

Theſe Sorts may alſo be propagated by Seeds, which they afford every Year in great Plenty: But as they are increaſed very faſt in the former Way, ſo it is hardly worth while to ſow their Seeds.

The 16th, 17th, and 18th Sorts are annual Plants, and ſhould either be ſown every Year, or their Seeds permitted to ſcatter themſelves; the latter of which is the ſureſt Method; for the Plants will come up in Autumn ſoon after the Seeds fall, and will abide the Winter, and flower early the ſucceeding Spring, whereby you will always be ſure to have their Seeds perfected, which does not conſtantly happen to thoſe ſown in the Spring. The 16th Sort is preſerved in many Gardens, for the ſweet Scent its Leaves afford when rubbed between the Fingers, which occaſion'd its being call'd *Muſk*, or *Muſcovy*. There is but little Beauty in the Flowers of this Plant; however, it may be admitted to have a Place in ſome odd Corner, or ſhady Border in a Garden, for Variety, it being very hardy, and will thrive in almoſt any Soil or Situation.

The 17th and 18th Sorts do produce very handſome Flowers; and as they are Plants which take up but little Room, and require very little Trouble to cultivate them, ſo it is worth while to allow them a Place, for Variety, in ſome Corner of the Garden, theſe being both as hardy as the former Sort.

The 19th, 20th, 21ſt, 22d, 23d, 24th, 26th, 27th, 28th, 29th, 30th, and 31ſt Sorts are Natives of a warmer Climate than ours, and require to be ſheltered in Winter: Theſe being all ſhrubby Plants, may be propagated by planting their Cuttings, any Time in Summer, in a Bed of light freſh Earth; obſerving to water and ſhade them until they have taken Root, which will be in about a Month's Time after planting; being careful to take off the Mats or other Covering every Night, that the Cuttings may have the Benefit of the Dews; as alſo, whenever there may happen to be any Showers in the Daytime, never to cover them but when the Sun ſhines very hot upon the Bed.

In this Place they may remain two Months from their firſt planting, by which Time they will be rooted ſufficient for tranſplanting; you muſt therefore prepare ſome Pots, which ſhould be about ſeven Inches over at the Top, theſe ſhould be filled with freſh light Earth, and having taken the Plants up, with as much Earth as poſſible to their Roots, you ſhould plant them into theſe Pots, each Plant into a ſeparate one, removing them into a ſhady Situation, until they have taken freſh Root, obſerving to water them frequently, as they may have occaſion: And when they are rooted, you ſhould remove them to a more expoſed Situation to harden them; in which Place they ſhould remain until the Middle of *October*, when the Mornings begin to be froſty, at which Time they ought to be removed into the Green-houſe, where they ſhould be placed as near the Windows as poſſible, obſerving to let the Windows be open, that they may have as much free Air as poſſible, until the Weather begins to be very cold.

Theſe Plants, during the Winter-ſeaſon, will require to be often refreſhed with Water; but they ſhould never have too much given them at once: They ſhould alſo be frequently pick'd, to take off all dead or decay'd Leaves, which, if ſuffer'd to remain upon them, will not only render the Plants unſightly, but alſo infect the Air of the Green-houſe, eſpecially when the Windows are kept ſhut cloſe, and thereby become injurious to all the Plants placed therein.

You muſt alſo obſerve to ſet them where they may be clear from the Heads of other Plants; for they will by no means bear to be ſtifled, which would cauſe them to caſt their Leaves: Nor do they require to be kept very warm in Winter; for if they are but ſcreen'd from the Froſt, it will be ſufficient; and all artificial Warmths are prejudicial to theſe Plants.

The 29th Sort is very ſubject to caſt its Leaves in the Autumn, and thereby appears to unſkilful Perſons as dead; but if it be ſuffer'd to remain in the Pot undiſturb'd, and very little Water given to it during this Seaſon, it will come out again in Winter as freſh and lively as before: But much Moiſture, during this State of Inactivity, very often deſtroys this Plant. This, for the Richneſs of the Colour of its Flowers, vaſtly exceeds all the other Sorts, tho' the 22d Sort is a very beautiful Flower, and continuing moſt part of the Summer and Autumn in flower, renders it very valuable; as is the 30th Sort, for the Beauty of its variegated Leaves.

The 32d and 33d Sorts are of humbler Growth than the former, tho' they are Natives of the ſame Country, and do therefore require the ſame Defence in Winter: Theſe may alſo be propagated by Heads cut off from the old Plants, and treated as was directed for the Cuttings of the ſhrubby Kinds. The 32d Sort is very ſubject to ramble, and affords Supply enough of Cuttings; but the 33d Sort increaſes much ſlower: This Plant is of an uncommon ſtrong ſweet Scent; the Leaves, when touch'd, ſmelling ſomewhat like *Anil-ſeed*: but the Flowers of neither of theſe two Sorts are very beautiful; however, they ſhould have a Place in all Collections of Plants for Variety's ſake.

Theſe Plants may alſo be propagated by ſowing of their Seeds in the Spring of the Year upon a moderate Hot-bed; and when they are come up two Inches high, they ſhould be planted into another Bed, with a little warm Dung under it to promote their Rooting: In this Bed they may be planted about ſix Inches ſquare; and when they are rooted, you ſhould harden them by Degrees; ſo that as the Weather becomes warmer, they may the better indure the open Air: In *July* you ſhould tranſplant them into Pots, (as was directed before for the Cuttings) and manage them in the ſame Manner. During the Summer-ſeaſon theſe Plants ſhould be ſet abroad with *Myrtles*, *Oleanders*, and other Green-houſe Plants, where, being artfully intermix'd therewith, they add greatly to the Variety, and continue flowering moſt part of the Year.

The 34th, 35th, 36th, and 37th Sorts have all knobby Roots, and increaſe but ſlowly thereby: Therefore, in order to have a Stock of theſe Plants, you ſhould carefully gather their Seeds, (which they ſeldom fail to produce every Year) and ſow them, as was directed for the other *African* Sorts, upon a moderate Hot-bed, managing them alſo accordingly, with this Difference only, *viz.* that they ſhould have leſs Water; and the Pots in which they are planted ſhould be ſmaller, eſpecially at firſt; for as they are Plants which make but ſmall Roots, ſo the putting them into large Pots is very prejudicial to them. Theſe are all eſteem'd for the Beauty of their Flowers, and their agreeable Sweetneſs in the Evening after the Sun has left them; for before that you cannnot perceive any Scent in them, tho' afterwards it becomes ſo ſtrong as to perfume the Air to ſome Diſtance from the Place where they ſtand. This, I ſuppoſe, may be accounted for from the Warmth of the Sun rarefying thoſe *Effluvia*, ſo as to be too minute to ſtrike our Organs of Smelling with any Force while the Heat is continued; but when the Cool of the Evening approaches, theſe *Effluvia* are of larger Bulk, and become perceptible to us in Proportion thereto.

During the Summer-ſeaſon theſe Plants may be expoſed, amongſt other Exoticks, in the open Air, being very careful not to give them too much Water, which often occaſions their rotting, eſpecially towards Autumn, when their green Leaves begin to decay, at which Time they ſhould have it very ſparingly; and if the Seaſon ſhould prove very wet, you ſhould move the Pots on one Side, or remove them under Shelter, to protect them from it: And about the Beginning of *October* you ſhould remove them into the Green-houſe, placing them as near as poſſible to the Windows, that they may have a good Quantity of free Air when the Windows are opened; for if they are defended from Froſt, and much Wet, it will be ſufficient, they not being extreme tender; nor will they ever require any artificial Warmths in Winter, but, on the contrary, as much Air as poſſible in mild Weather.

Theſe Plants require a very light ſandy Soil, but ſhould not have too much Dung. The Mixture of Earth in which I find them grow beſt, is as follows: 1ſt, Take a Quantity of freſh Earth from a Paſture-Ground that is inclining to a Sand, (and if you have Time for the Turf to rot before you have Occaſion for it, add that to the Earth) then mix about a third or fourth Part as much Sea-ſand, in Proportion to the Lightneſs of your Soil; add to this about a fourth Part as much rotten Tanners-bark; mix all well together, and let it lie in a Heap two or three Months before you have Occaſion for it, obſerving to turn it over two or three Times, that the Mixtures may be the better united; and if, before it be us'd, you paſs it thro' a rough Screen to take out all large Stones, Roots, &c. it will be the better: but by no means ſift the Earth fine, as is the Practice of many People; for I am ſure it is doing a great deal of Damage, (as was ſhewn under the Article *Abies*): When theſe Plants are potted, you ſhould carefully lay ſome Stones or Shreds in the Bottom of the Pots, that the Water may the better paſs off: Nor ſhould you plant them in Pots too large; which is equally injurious to them, (as was before mentioned).

The 38th and 39th Sorts are Plants of ſhorter Duration than thoſe above-mentioned, rarely continuing above two Years; ſo that, in order to preſerve theſe, you ſhould ſave the Seeds every Year, which ſhould be ſown upon a moderate Hot-bed in the Spring, and managed as was directed for the laſt mentioned Sorts: Theſe do often produce Flowers and Seeds the ſame Summer; but the ſecond Year, provided they are defended from the Froſt in Winter, they will flower early, and perfect their Seeds before Autumn.

The 40th Sort is annual: This muſt be ſown on a moderate Hot-bed, and the Plants brought forward in the Spring; but when they begin to flower, muſt be ſet in the open Air, otherwiſe the Flowers will fall away without producing any Seeds. This, tho' a Plant of no great Beauty, yet is worthy of a Place in every Collection of curious Plants.

There are a great Number of *Geraniums* which I have not here mentioned, many of which are Natives of *England*, and others were brought from divers other Parts of *Europe*; but as theſe, for the moſt part, are annual Plants of no Beauty or Uſe, ſo I thought it needleſs to trouble myſelf or the Reader therewith.

GERMANDER. *Vide* Chamædrys.

GESNERA.

This Plant was ſo named by Father *Plumier*, who diſcovered it in *America*, in Honour to *Conrad Geſner*, a very learned Botaniſt, and natural Hiſtorian.

The *Characters* are;

It hath an anomalous perſonated Flower, conſiſting of one Leaf, from whoſe Cup ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower; which afterward becomes a membranaceous Fruit, divided into two Cells, which are filled with ſmall Seeds.

The *Species* are;

1. **Gesnera** *humilis, flore flaveſcente. Plum. Nov. Gen.* Low Geſnera, with a yellowiſh Flower.
2. **Gesnera** *amplo digitalis folio tomentoſo. Plum. Nov. Gen.* Geſnera with a large woolly fox-glove Leaf.
3. **Gesnera** *arboreſcens, amplo flore fimbriato & maculoſo. Plum. Nov. Gen.* Tree-like Geſnera, with a large furbelowed and ſpotted Flower.

The firſt and ſecond Sorts were found by the late Dr. *William Houſtoun* in *Jamaica*, from whence he ſent their Seeds to *England*; but by their being a long Time out of the Ground, there was not any of them which grew. The third Sort was diſcovered by Father *Plumier* at *Martinico*; this Sort riſes to the Height of eight or ten Feet, and has a woody Stem; but the other two Sorts ſeldom riſe above three Feet high.

Theſe Plants are propagated by Seeds, which ſhould be ſown as ſoon as poſſible after they are ripe; for being very ſmall and light, if they are kept long out of the Ground, they will not grow: Therefore the ſureſt Method to obtain theſe Plants, is to procure them in Tubs of Earth from *America*. The Seeds ſhould be ſown in the Tubs filled with freſh Earth, and placed in a ſhady Situation; and when the Plants come up, they muſt be frequently watered, and kept clear from Weeds. Theſe Tubs ſhould remain in the Country, until the Plants are pretty ſtrong; for if they are ſent over too young, they will be in great Danger of periſhing before they arrive in *England*. When they are put on board the Ship, they ſhould be covered in the Heat of the Day with Tarpaulins, to ſcreen them from the violent Heat of the Sun, as alſo in bad Weather to prevent the Salt-Water from waſhing of them. During their Paſſage they ſhould be often refreſhed with Water, while they are in a warm Latitude; and ſhould have as much Air as poſſible, when the Weather will permit; but as they arrive in a cooler Latitude, ſo they muſt have a leſs Quantity of Water given to them, and ſhould be ſcreened from the Cold.

When theſe Plants arrive in *England*, they ſhould be carefully taken out of the Boxes, and each planted into a Pot, filled with rich light Earth, and then plunged into a Hot-bed of Tanners-bark, obſerving to water them, and ſcreen them from the Heat of the Sun until they have taken Root; after which Time they ſhould have freſh Air admitted to them in proportion to the Warmth of the Seaſon, and muſt be frequently watered. In this Bed the Plants may remain until *Michaelmas*, when they ſhould be removed into the Stove, and plunged into the Tan: During the Winter Seaſon they will require to be frequently watered, but it muſt not be given in large Quantities; but in Summer they muſt be plentifully watered in hot Weather. As theſe Plants are too tender to endure the Cold of our Air even in Summer, ſo they muſt conſtantly remain in the Stove, where in Winter they muſt be kept very warm; but in Summer they muſt have a large Share of freſh Air in warm Weather; and if their Leaves contract Filth, it muſt be carefully waſhed off; otherwiſe it will harbour Inſects, which will in Time deſtroy the Plants. With this Management the Plants will thrive, and produce Flowers, which will afford an agreeable Variety amongſt other tender exotick Plants in the Stove.

GEUM, [is ſo call'd of Γῆ, *the Earth*, q. d. *Earth-herb*, or, *growing near the Earth*; becauſe its Leaves touch the Ground] Hairy Kidneywort, *or* Sanicle.

The *Characters* are;

The Cup of the Flower is quinquifid: The Flower conſiſts of five Leaves, which expand in form of a Roſe, *having eight or ten* Stamina *or Threads ſurrounding the Ovary: The Fruit is roundiſh, and is ſplit into two Horns at the Top; this becomes a bicapſular Seed-veſſel containing many ſmall Seeds.*

The *Species* are;

1. **Geum** *paluſtre minus, foliis oblongis crenatis. Tourn.* Hairy Kidneywort, *or* Water Sanicle.
2. **Geum** *anguſtifolium autumnale, flore luteo guttato. Tourn.* Narrow-leaf'd autumnal Sanicle, with a yellow-ſpotted Flower.
3. **Geum** *rotundifolium majus. Tourn.* Great round-leaf'd ſpotted Sanicle.
4. **Geum** *folio ſubrotundo majori, piſtillo floris rubro. Tourn.* *London* Pride, *or* None ſo Pretty.
5. **Geum** *rotundifolium minus. Tourn.* Leſſer round-leav'd Sanicle.
6. **Geum** *folio circinato, piſtillo floris pallido. Tourn.* Round-leav'd Sanicle, with a pale Pointal.
7. **Geum** *folio ſubrotundo minori, piſtillo floris rubro. Tourn.* Sanicle with a leſſer roundiſh Leaf, and a red Pointal.
8. **Geum** *folio circinato, acutè crenato, piſtillo floris rubro. Tourn.* Sanicle with a round ſharp jagged Leaf, and a red Pointal.
9. **Geum** *folio ſubrotundo minimo. Tourn.* Sanicle with a very ſmall roundiſh Leaf.
10. **Geum** *Creticum, folio circinato villoſo, flore magno albo. Tourn. Cor.* *Candy* Sanicle, with a round hairy Leaf, and a large white Flower.
11. **Geum** *orientale rotundifolium ſupinum, flore aureo. Tourn. Cor.* Low round-leav'd Eaſtern Sanicle, with a golden Flower.
12. **Geum** *orientale, cymbalariæ folio molli & glabro, flore magno albo. Tourn. Cor.* Eaſtern Sanicle, with a ſoft ſmooth ivy-wort Leaf, and a large white Flower.

The firſt of theſe Plants is found wild upon the Mountains of *Wales* and *Weſtmorland*, but will grow, if tranſplanted into a cool moiſt Place in a Garden: But the ſureſt Method is to plant them in Pots fill'd with ſtrong poor Earth; and place them in a ſhady Situation, where, if they are conſtantly watered in dry Weather, they will thrive, and produce Flowers.

The ſecond is found in ſome Parts of *Cheſhire*: This alſo delights in a ſtrong moiſt Soil, and a ſhady Situation; nor ſhould theſe Plants be often tranſplanted, for they delight beſt in a poor Soil, and want very little Culture, therefore the beſt Method is to furniſh yourſelf with Roots from their natural Places of Growth; for their Seeds ſeldom ſucceed if ſown: Theſe ſhould be taken up with as much Earth about their Roots as poſſible) then plant them in ſome cold ſhady Part of the Garden, (but not under the Drip of Trees) where, when they are once well fix'd, they will continue without any farther Care for ſeveral Years, and will annually produce large Quantities of beautiful Flowers: And with theſe Plants may ſuch Parts of a Garden, where few other Things will thrive, be ſupply'd to great Advantage: So that did we but conſider well what Plants delight in moiſt and ſtrong Soils, and a ſhady Situation, and what require a dry light Soil, and a ſunny Expoſure, we need never be at a Loſs for Plants to imbelliſh a Garden, be the Soil or Situation what it will: And 'tis for want of rightly conſidering how to adapt the proper Plants to each Soil and Situation, that we often ſee Natives of a low Valley planted upon a dry barren Soil, and thoſe of dry ſandy Hills on a ſtrong rich Soil; in both which Caſes they ſtarve, and come to nothing.

The third Sort is ſeldom planted in Gardens, except where the Owners are curious in Collections of Plants; but yet it well deſerves a Place amongſt the former in a cool ſhady Border, where it will thrive very well.

The fourth Sort is the moſt common in the Gardens, and was formerly in greater Requeſt than at preſent, it having been in great Uſe for bordering of Flower-beds; but as it increaſes very faſt ſo it is apt to ſpread too far, and ſometimes decays in Patches, which renders it very unſightly: Beſides, it muſt be tranſplanted at leaſt once a Year, otherwiſe it cannot be kept in any tolerable Order; however, a few Plants of this Kind may be preſerved as proper Furniture for ſhady Borders; but it will grow upon a drier Soil than any of the former Sorts.

The fifth, ſixth, ſeventh, eighth, and ninth Sorts grow on the *Alps* and *Appennines* in Plenty, from whence they have been tranſplanted into ſome curious Gardens by Lovers of Variety: They are all extreme hardy Plants, ſo ſhould be planted in ſhady moiſt Places, and a poor Soil, where they will thrive much better than in an open Situation. They are propagated by Off-ſets, which they ſend forth in great Plenty; the beſt Seaſon for this Work is in *October*, that the Plants may be well rooted before Spring, otherwiſe they will not flower ſo ſtrong the following Summer. Some of theſe Plants were formerly planted for Edgings on the Sides of Borders in the Flower-Garden, but they are by no means fit for this Purpoſe; becauſe they ramble too far, and are very ſubject to decay in Patches, which breaks the Edging, and renders it unſightly; ſo that they appear more beautiful, when planted in Patches on ſhady moiſt Borders, where few other Plants will thrive; in ſuch Places theſe Plants will make a pretty Variety. They flower in *May*, and ſome of them will produce good Seeds in Autumn: but as they increaſe ſo faſt by Off-ſets, ſo few Perſons regard their Seeds.

The laſt three Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, who ſent them to the *Royal Garden* at *Paris*. Theſe are not quite ſo hardy as the former Sorts, but will endure the Cold of our ordinary Winters very well in the full Ground, being never deſtroyed but by extreme hard Froſt. Theſe may be propagated by Off-ſets, in the ſame Manner as the former Sorts, and ſhould have a ſhady Situation.

GILLIFLOWER, *or* JULY-FLOWER. *Vide* Caryophyllus.

GILLIFLOWER, *or* STOCK-GILLIFLOWER. *Vide* Leucoium.

GILLIFLOWER, the Queen's *or* Dame's-Violet. *Vide* Heſperis.

GINGER. *Vide* Zinziber.

GINGIDIUM. *Vide* Viſnaga.

GLADE, is an open and light Paſſage made thro' a Wood, by lopping off the Branches of Trees along that Way.

GLADIOLUS, [takes its Name of *Gladius*, Lat. *a Sword*, q. d. *little Sword*; becauſe the Leaves of this Plant reſemble a Sword] Corn-flag.

The *Characters* are;

It hath a fleſhy, double, tuberoſe Root: The Leaves are like thoſe of the Fleur-de-Lis: *The Flower conſiſts of one Leaf, and is ſhaped like a* Lily, *ſpreading open at the Top into two Lips; the upper one being imbricated, and the under one divided into five Segments: The Ovary becomes an oblong Fruit divided into three Cells, which are fill'd with roundiſh Seeds wrapt up in a Cover.*

The *Species* are;

1. GLADIOLUS *utrinque floribus. C. B. P.* Corn-flag, with Flowers on both Sides the Stalks.
2. GLADIOLUS *carnei coloris. Swert. Flor.* Fleſh-colour'd Corn-flag.
3. GLADIOLUS *floribus uno verſu diſpoſitis, major, floris colore purpureo-rubente. C. B. P.* Great Corn-flag, with reddiſh-purple Flowers rang'd on one Side the Stalk.
4. GLADIOLUS *major Byzantinus. C. B. P.* Great Corn-flag of *Conſtantinople*.
5. GLADIOLUS *utrinque floribus, floribus albis. H. R. Monſp.* Corn-flag, with white Flowers rang'd on each Side the Stalk.
6. GLADIOLUS *maximus Indicus. C. B. P.* The largeſt *Indian* Corn-flag.
7. GLADIOLUS *floribus uno verſu diſpoſitis, major & procerior, flore candicante. C. B. P.* Greater and taller Corn-flag, with whitiſh Flowers ranged all on one Side.
8. GLADIOLUS *floribus uno verſu diſpoſitis, minor & humilior. C. B. P.* Smaller and lower Corn-flag, with Flowers ranged on one Side.
9. GLADIOLUS *minor, floribus uno verſu diſpoſitis incarnatis. H. L.* Smaller Corn-flag, with fleſh-coloured Flowers ranged on one Side.
10. GLADIOLUS *utrinque floribus, flore rubro. C. B. P.* Corn-flag, with red Flowers on both Sides.
11. GLADIOLUS *floribus uno verſu diſpoſitis, minor. C. B. P.* Smaller Corn-flag, with Flowers ranged on one Side.

Theſe are all propagated by their tuberoſe Roots, which the firſt, ſecond, and fifth Sorts produce in great Plenty; ſo that in a few Years, if they are ſuffer'd to remain unremov'd, they will ſpread very far, and are hardly to be intirely rooted out when they have once gotten Poſſeſſion of the Ground. Theſe Roots are in Shape very like thoſe of the large yellow Spring *Crocus*, but are ſomewhat bigger, yellower within, and have a rougher outer Coat or Covering. The ſmall Off-ſets of theſe Roots will produce Flowers the ſecond Year; therefore when the old Roots are tranſplanted, the Off-ſets ſhould be taken off from them, and planted into a Nurſery-bed for one Year, by which time they will be fit to tranſplant into the Borders of the Pleaſure-Garden. Theſe Roots may be taken up in *July*, when their Leaves decay, and may be kept out of the Ground until *October*; at which time they ſhould be planted into the Borders of the Pleaſure-Garden, intermixing them amongſt other bulbous-rooted Plants: But if you plant them in large Borders in Wilderneſs-work, (where they will thrive and flower very well) they need not be tranſplanted oftener than every other Year, or once in three Years; whereas in Borders of a Pleaſure-Garden, if they were ſuffer'd to remain ſo long, they would over-run the Ground, and be very troubleſome.

The third and fourth Sorts are the moſt valuable, producing taller Stalks, and fairer Flowers: Nor are theſe ſo apt to increaſe, which renders them fitter for the Borders of a Flower-Garden; ſo that ſince theſe have been introduced and become common, the other Sorts have been rejected, unleſs in ſome old Gardens, or for large Wilderneſs Quarters, where they will grow better than the two laſt mentioned.

Theſe Plants may alſo be propagated by Seeds, which ſhould be ſown in Pots or Tubs of light freſh Earth ſoon after they are ripe: Theſe Tubs ſhould be placed where they may enjoy the Morning Sun until eleven o' Clock, in which Poſition they ſhould remain until *October*; at which time they muſt be removed where they may have the full Sun during the Winter-Seaſon, and the *March* following the young Plants will begin to appear, when the Boxes or Pots ſhould have a little fine Earth ſifted over the Surface of the Ground, and be removed again where they may have only the Morning Sun; obſerving, during the time of their Growth, to refreſh them with Water in dry Weather, as alſo to keep them clear from Weeds.

The *Michaelmas* following, if the Plants are very thick in the Pots or Boxes, you ſhould prepare a Bed or two of light freſh Earth, in Proportion to the Quantity of your young Plants; and after levelling the Surface very even, you ſhould ſpread the Earth of the Pots in which the Roots are contain'd as equal as poſſible upon the Beds, (for the Roots at this time will be too ſmall to be eaſily taken up) covering the Bed about half an Inch thick with light ſifted Earrh; and the Spring following, when the Plants begin to come up, you muſt ſtir the Ground upon the Surface to looſen it, and carefully clear the Bed from Weeds: In theſe Beds they may remain (obſerving in the Autumn to ſift ſome freſh Earth over the Surface) until the fourth Year, by which time they will begin to ſhew their Flowers; therefore you may now obſerve to mark out all the beſt Kinds as they blow, which may the ſecond Year be tranſplanted into the Pleaſure-Garden, but the poorer Kinds ſhould be thrown out as not worth preſerving: for the good Sorts will ſoon multiply and furniſh you with a ſufficient Stock from Off-ſets.

The *Indian Corn-flag* is tender, and muſt be preſerv'd in a warm Green-houſe, or a moderate Stove, during the Winter-Seaſon. Theſe Roots ſhould be planted in Pots fill'd with a light ſandy Soil. The beſt time to tranſplant them is any time from *May*, at which time their green Leaves decay till *September*, that they begin to ſhoot again; and in *October* the Pots ſhould be removed into the Green-houſe: And during their Seaſon of Growth, which is chiefly in Winter, they muſt be frequently water'd; but you muſt not give it them in large Quantities; but during the Summer-ſeaſon, if they are ſuffered to remain in the Pots, they ſhould have little Moiſture, but only be remov'd to a ſhady Place; for much Wet at the time their Roots are inactive is apt to rot them.

This Plant but rarely flowers with us; but when it doth, it makes a beautiful Appearance in the Green-houſe, eſpecially coming in *January*, when few other Flowers appear, which renders it worthy of a Place in every curious Garden.

GLANDIFEROUS Trees, are ſuch Trees as bear Maſt; as *Acorns*, &c.

GLANDULOUS Roots, are ſuch Roots as grows Kernel-wiſe.

GLANS, is that Sort of Fruit which is contain'd within a ſmooth, but hard Bark, having but one Seed; its hinder Parts cover'd with a kind of Cup, the fore Part being bare, as *Acorns*: but it is properly the Fruit without the Cup.

GLASTENBURY-THORN. *Vide* Meſpilus.

GLAUCIUM, [is ſo called of γλαυκὸς, Gr. becauſe the Leaves of this Plant are of Sea-green Colour: It is call'd the *Horned Poppy*, becauſe it is a Species of *Poppy*, having Huſks reſembling Horns.] The Horned Poppy.

The *Characters* are;

The Cup of the Flower conſiſts of two Leaves: The Flower hath five Leaves, which are placed orbicularly, and expand in form of a Roſe or a Poppy, but ſoon fall away: The Ovary ariſes from the Bottom of the little Placenta, and is divided into two Parts at the Extremity; this becomes a long taper Pod, which is bivalve, having an intermediate Partition, to which are faſten'd many roundiſh Seeds.

The *Species* are;

1. Glaucium *flore luteo. Tourn.* Yellow Horned Poppy.
2. Glaucium *flore violaceo. Tourn.* Blue flower'd Horned Poppy.
3. Glaucium *hirſutum, flore Phœnicio. Tourn.* Hairy Horned Poppy, with a deep-ſcarlet Flower.
4. Glaucium *glabrum, flore Phœnicio. Tourn.* Smooth Horned Poppy, with a deep-ſcarlet Flower.
5. Glaucium *orientale, flore magno rubro. Tourn. Cor. Eaſtern* Horned Poppy, with a large red Flower.

The firſt Sort is found upon the Sea Coaſts in ſome Parts of *England*; but if ſown in a Garden, will grow very well: This is a perennial Plant, the Roots abiding, if in a poor dry Soil, two or three Years: but when planted in a moiſt, or very rich Soil, it ſeldom continues above one Year, eſpecially if it flowers the firſt Summer.

The ſecond Sort Mr. *Ray* found growing amongſt Corn, betwixt *Swafham* and *Burwel* in *Cambridgeſhire*.

The third and fourth Sorts were brought from Abroad: Theſe three are annual Plants, and either ſhould be ſown every Spring, or their Seeds ſuffered to ſcatter themſelves; for the Plants will ariſe in Autumn from the Seeds which fall; and if the Winter does not prove too ſharp, they will abide without any Care, and flower early the ſucceeding Spring. Theſe Plants, tho' there is not much Beauty in them, yet may be permitted to have a Place in large Gardens, for Variety, eſpecially as they require very little Culture. They delight moſt in a warm light Soil; but will grow in almoſt any Soil, if it be not over-dunged.

The fifth Sort was found by Dr. *Tournefort* in the *Levant*, who ſent the Seeds to *Paris*. It is a biennnial Plant, which may be propagated by Seeds, as the other Sorts; but ſhould have light poor Soil, in which it will endure the Cold of the Winter, much better than if ſown on a rich Ground.

GLAUX, Sea Milk-wort.

The *Characters* are;

It hath a bell-ſhaped Flower, conſiſting of one Leaf, whoſe Brims are expanded and cut into ſeveral Segments; from the Center ariſes the Pointal, which afterwards becomes a round Fruit or Huſk, opening from the Top downwards, and filled with ſmall Seeds.

The *Species* are;

1. Glaux *maritima. C. B. P.* Sea Milk-wort, or black Salt-wort.
2. Glaux *maritima, flore albo. Tourn.* Sea Milk-wort, with a white Flower.
3. Glaux *paluſtris, flore ſtriato clauſo, foliis portulacæ. Tourn.* Marſhy Milk-wort, with a ſtriped Flower, and purſlane Leaves.

Theſe Plants grow wild in *England*, and are rarely preſerved in Gardens, unleſs for the ſake of Variety. They may be taken up in the Places of their Growth, and planted in Pots, filled in poor gravelly Earth, and in Summer muſt be frequently watered: with this Management they may be preſerved, and they will produce Flowers every Year.

GLOBULARIA.

The *Characters* are;

It hath a floſculous Flower, conſiſting of many Florets, which are divided into ſeveral Segments, and have one Lip; theſe are contained in a proper Empalement, out of the Bottom of which ariſes the Pointal, fixed like a Nail to the lower Part of the Floret, and becoming a Seed, hidden in the Capſule, which before was the Empalement of the Floret. On that Capſule ſit the Placenta's, which occupy the middle Part of the common Empalement.

The *Species* are;

1. Globularia *vulgaris. Tourn.* Common Globularia.
2. Globularia *Pyrenaica, folio oblongo, caule nudo. Tourn. Pyrenean* Globularia, with an oblong Leaf, and naked Stalk.
3. Globularia *montana humillima repens. Tourn.* The loweſt creeping Mountain Globularia.
4. Globularia *fruticoſa, myrti folio tridentato. Tourn.* Shrubby Globularia, with a trifid myrtle Leaf.
5. Globularia *Africana fruteſcens, thymeleæ folio lanuginoſo. Tourn.* Shrubby *African* Globularia, with a woolly ſpurge-laurel Leaf.
6. Globularia *ſpinoſa. Tourn.* Prickly Globularia.
7. Globularia *Alpina minima, origani folio. Tourn.* The ſmalleſt *Alpine* Globularia, with a wild-marjoram Leaf.
8. Globularia *orientalis, floribus per caulem ſparſis. Tourn. Cor. Eaſtern* Globularia, with Flowers ſcattered along the Stalks.
9. Globularia *orientalis, flore ampliſſimo. Tourn. Cor. Eaſtern* Globularia, with a very large Flower.

The firſt of theſe Plants grows plentifully about *Montpelier*, as alſo at the Foot of the Mountains *Jura* and *Saleva*, and in many other Parts of *Italy*, and in *Germany*. This Plant hath Leaves very like thoſe of the *Daizy*, but are thicker and ſmoother; the Flowers grow on Foot-ſtalks, which are about ſix Inches high, and are of a globular Form.

The ſecond Sort grows plentifully in the Woods, and on the *Pyrenean* Mountains; this is much larger than the former, and the Foot-ſtalk is quite naked; the Leaves are narrower and much longer.

The third Sort is a very low Plant, whoſe Branches trail on the Ground, and ſtrike Roots out from their Joints, whereby it propagates itſelf very faſt. The Flowers grow on ſhort Foot-ſtalks, and are of a blue Colour.

The firſt and ſecond Sorts may be propagated by parting of their Roots, after the manner of *Daizies*; but the third Sort is eaſily propagated from the trailing Branches, which take Root. The beſt Seaſon for parting and tranſplanting of theſe Plants, is in *September*, that they may take new Root before the froſty Weather comes on: they ſhould be planted in Pots, filled with freſh Earth, and placed in a ſhady Situation until they have taken Root; after which time they may be expoſed to the open Air until the Beginning of *November*, when it will be proper to place them under a Garden-frame, where they may be protected from ſevere Froſt, which ſometimes deſtroys them in this Climate; but they ſhould have as much free Air as poſſible in mild Weather. In the Summer Seaſon they ſhould be placed where they may have the Morning Sun, and in dry Weather ſhould be frequently refreſhed with Water. With this Management they will increaſe, and produce their Flowers every Year, but they rarely perfect their Seeds in this Country.

The fourth Sort grows about *Montpelier* in *France*, and in *Valentia*, and ſeveral other Parts of *Spain*. This has a hard woody Stem, and riſes to about two Feet high, having many woody Branches, beſet with Leaves like thoſe of the *Myrtle-tree*; on the Top of the Branches the Flowers are produced, which are of a blue Colour, and globe-ſhaped. This Plant may be propagated by Cuttings, which ſhould be cut off in *April*, juſt before they begin to make new Shoots; theſe Cuttings ſhould be planted into Pots, filled with light freſh Earth, and then placed into a very moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; when they may be taken out of the Bed, and inured to bear the open Air by Degrees. In Summer theſe Plants may be expoſed with other hardy exotic Plants; and in Winter they ſhould be placed under a Hot-bed Frame, where they may enjoy the free Air in mild Weather, but ſhould be ſcreened from hard Froſt, which will deſtroy them, if they are expoſed thereto. This Plant never produces good Seeds in this Country.

The fifth Sort grows in the Country about the *Cape of Good Hope*; this is a Shrub which riſes to the Height of ſeven or eight Feet, and divides into many Branches, which are cloſely beſet with thick ſtiff Leaves, much like thoſe of the *Cneorum Matthioli*; at the Diviſion of the Branches, the Flowers are produced, which are round, woolly, and of a ſilver Colour, and at firſt have the Appearance of the Katkin of the *Mountain Oſier*. This Shrub may be propagated by Cuttings, which ſhould be planted in *April*, juſt as the Plant begins to ſhoot, in Pots filled with freſh light Earth, and plunged into a very moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which time you muſt inure them by Degrees to bear the open Air; then they muſt be taken out of the Hot-bed, and may be placed amongſt other Exotics in a well ſheltered Situation, obſerving to water them in dry Weather; in this Place they may remain till *October*, when they ſhould be removed into the Green-houſe, and placed where they may have as much free Air as poſſible in mild Weather; for this Plant only requires to be ſcreened from Froſt, being tolerably hardy: with this Management the Plants will thrive exceedingly, and in a few Years will produce Flowers.

The ſixth Sort was found in the Mountains of *Granada*, by D. *Albinus*. This Plant is of low Growth, and may be propagated as the firſt Sort, as may alſo the ſeventh Sort, which is the leaſt of all the Sorts, and the moſt hardy; ſo that it ſhould have a ſhady Situation in Summer, but in Winter it will be proper to ſhelter them from ſevere Froſt.

The eighth and ninth Sorts were found by Dr. *Tournefort*, in the *Levant*; theſe are ſomewhat tender, and ſhould be ſheltered from the Froſt in Winter, but in Summer they may be expoſed with other hardy exotic Plants, and require to be frequently watered in dry Weather. Theſe may be propagated by Seeds, or by parting of their Roots, as was directed for the former Sorts.

GLYCYRRHIZA, [is ſo call'd of γλυκὺς, *ſweet*, and ῥίζα, Gr. a *Root*, q. d. *Sweet Root*: The Antients call'd it *Scythian Root*, becauſe the *Scythians* firſt brought it into Uſe.] Liquorice.

The *Characters* are;

It hath a papilionaceous Flower: The Pointal which ariſes from the Empalement becomes a ſhort Pod, containing ſeveral Kidney-ſhap'd Seeds: The Leaves are plac'd by Pairs joined to the Mid-rib, and are terminated by an odd Lobe.

The *Species* are;

1. GLYCYRRHIZA *ſiliquoſa, vel Germanica. C. B. P.* Common Liquorice.
2. GLYCYRRHIZA *capite echinato. C. B. P.* Rough-podded Liquorice.
3. GLYCYRRHIZA *orientalis, ſiliquis hirſutiſſimis. Tourn. Cor.* *Eaſtern* Liquorice, with hairy Pods.

The firſt of theſe Plants is what the People cultivate for Uſe.

This Plant delights in a rich, light, ſandy Soil, which ſhould be three Feet deep at leaſt; for the greateſt Advantage conſiſts in the Length of the Roots: The greateſt Quantity of Liquorice which is propagated in *England* is about *Pontefract* in *Yorkſhire*, and *Godliman* in *Surry*; tho' of late Years there hath been a great deal cultivated in the Gardens near *London*: The Ground in which you intend to plant *Liquorice* ſhould be well dug and dunged the Year before you plant it, that the Dung may be perfectly rotted and mixed with the Earth, otherwiſe it will be apt to ſtop the Roots from running down; and before you plant it the Ground ſhould be dug three Spades deep, and laid very light: When your Ground is thus well prepared, you ſhould furniſh yourſelf with freſh Plants taken from the Sides or Heads of the old Roots; obſerving that they have a good Bud or Eye, otherwiſe they are ſubject to miſcarry: Theſe Plants ſhould be about ten Inches long, and perfectly ſound.

The beſt Seaſon for planting them is towards the End of *February*, or the Beginning of *March*, which muſt be done in the following Manner; *viz.* Firſt ſtrain a Line croſs the Ground in which you ſhould plant them; then with a long Dibble made on purpoſe, put in the Shoot, ſo that the whole Plant may be ſet ſtrait into the Ground, with the Head about an Inch under the Surface in a ſtrait Line, about a Foot aſunder, or more, in Rows, and two Feet Diſtance Row from Row; and after having finiſh'd the whole Spot of Ground, you may ſow a thin Crop of Onions, which being Plants that don't root deep into the Ground, nor ſpread much above Ground, will do the *Liquorice* no Damage the firſt Year; for the *Liquorice* will not ſhoot very high the firſt Seaſon, and the houghing of the Onions will alſo keep the Ground clear from Weeds: but in doing of this, you muſt be careful not to cut off the top Shoots of the *Liquorice* Plants, as they appear above Ground, which would greatly injure them, and alſo obſerve to cut up all the Onions which grow near the Heads of the *Liquorice*; and after your Onions are pulled up, you ſhould carefully hough and clear the Ground from Weeds: And in *October*, when the Shoots of the *Liquorice* are decayed, you ſhould ſpread a little very rotten Dung upon the Surface of the Ground, which will prevent the Weeds from growing during the Winter; and the Rain will waſh the Virtue of the Dung into the Ground, which will greatly improve the Plants.

In the Beginning of *March* following you ſhould ſlightly dig the Ground between the Rows of *Liquorice*, burying the remaining Part of the Dung: But in doing of this, you ſhould be very careful not to cut the Roots. This ſtirring of the Ground will not only preſerve it clean from Weeds a long time, but alſo greatly ſtrengthen the Plants.

The Diſtance which I have allowed for planting theſe Plants, will, I doubt not, by ſome, be thought too great: But in anſwer to that, I would only obſerve, that as the Largeneſs of the Roots are the chief Advantage to the Planter, ſo the only Method to obtain this, is by giving them Room: And beſides, this will give a greater Liberty to ſtir and dreſs the Ground, which is of great Service to *Liquorice*; and if the Plantation deſign'd were to be of an extraordinary Bigneſs, I would adviſe the Rows to be made at leaſt three Feet diſtant, whereby it will be eaſy to ſtir the Ground with a Breaſt-plough, which will greatly leſſen the Expence of Labour.

Theſe Plants ſhould remain three Years from the time of planting, when they will be fit to take up for Uſe, which ſhould not be done until the Stems are perfectly decay'd; for when it is taken up too ſoon, it is ſubject to ſhrink greatly, and loſe of its Weight.

The Ground near *London* being rich, increaſes the Bulk of the Root very faſt; but when it is taken up, it appears of a very dark Colour, and not near ſo ſightly as that which grows upon a ſandy Soil in an open Country.

The firſt Sort is that which is commonly cultivated in *England* for Medicine; the other two Kinds are preſerved in curious Botanick Gardens for Variety; but their Roots are not ſo full of Juice as the firſt, nor is the Juice ſo ſweet: tho' the ſecond Sort ſeems to be that which *Dioſcoridis* has deſcribed and recommended; but I ſuppoſe the Goodneſs of the firſt has occaſioned its being ſo generally cultivated in *Europe*.

Theſe two Sorts laſt-mentioned perfect their Seeds in *England*, by which they may be propagated, whereas the common Sorts ſeldom produce any in this Country. They may alſo be propagated by Roots, as the common Sort.

GNAPHALIUM, [takes its Name of γναφάλιον, Gr. *Flocks*, or *clipt Locks of Wool*: or of γνάπτω, Gr. *to comb*; becauſe its external Down looks like Combings.] Cud-weed.

The *Characters* are;

It hath downy Leaves: The Cup of the Flower is ſcaly, neither ſhining nor ſpecious: The Flowers are divided or cut in form of a Star.

The *Species* are;

1. GNAPHALIUM *Anglicum. Ger.* Long-leaf'd, upright Cud-weed.
2. GNAPHALIUM *minus, ſeu herba impia. Park.* Common Cud-weed.
3. GNAPHALIUM *maritimum. C. B. P.* Sea Cud-weed, or Cotton-weed.

Theſe two firſt Sorts are found wild in divers Parts of *England*, upon moiſt, ſtony Heaths, eſpecially in ſuch Places where the Water ſtood during the Winter. The ſecond Sort is placed in the Catalogue of Simples annexed to the *College Diſpenſatory*, but is not often uſed in Medicine: Theſe Plants are ſeldom propagated in Gardens, except for the ſake of Variety; for they have no great Beauty, nor are of much Uſe. There are alſo many more of this Kind, ſome of which grow wild in *England*; but as they are never cultivated, I ſhall paſs them over without naming, and proceed to the third Sort, which is often preſerved in curious Gardens for the Variety of its fine Silver-colour'd Leaves: This Plant is found upon the Sea-coaſts of *Cornwal*, and ſome other Parts of *England*; but yet will rarely abide the Cold of our Winters near *London*, if planted in the open Air; but if it be preſerv'd in a common Frame from the Severity of Froſt, it will thrive very well: This is propagated by planting its Cuttings in any of the Summer Months, obſerving to water and ſhade them from the Violence of the Sun in the Middle of the Day; and in about two Days they will be rooted enough to tranſplant; at which time you ſhould provide a Parcel of ſmall Pots, which ſhould be fill'd with light ſandy Earth, planting your young Plants therein, ſhading them again until they have taken new Roots; after which they may be expoſed until the End of *October*, when you ſhould remove the Pots into Shelter for the Winter Seaſon. But altho' I have adviſed the planting theſe Plants into Pots, yet, if you have a Stock of them, you may plant ſome of them under a warm Wall, where they will ſtand very well in mild Winters; but in very ſharp Froſts they are generally deſtroyed. They muſt be frequently water'd in dry Weather, otherwiſe they will not flower.

GNAPHALODES.

The *Characters* are;

It is a Plant with a floſculous Flower, conſiſting of ſeveral barren Florets; the Embryos which conſtituted the Empalement of the Flower, become a creſted Fruit, pregnant with a Seed for the moſt part oblong.

We have but one *Species* of this Plant at preſent in *England*, which is;

GNAPHALODES *Luſitanica. Tourn.* Portugal Gnaphalodes.

This is a low annual Plant, which ſeldom riſes above four Inches high, but divides into ſeveral trailing Branches, which are beſet with ſmall ſilver-coloured Leaves, which have a great Reſemblance to thoſe of Cudweed; but the Flowers are ſo ſmall as not to be conſpicuous, unleſs they are magnified by a Glaſs. This Plant is ſeldom preſerved in Gardens, unleſs it be for the ſake of Variety, for there is little Beauty in it. The Seeds of this Plant may be ſown the Beginning of *April*, on a Bed of light Earth, in an open Situation; and when the Plants are come up, they ſhould be kept clean from Weeds, and in very dry Weather they ſhould be ſometimes refreſhed with Water: with this Management the Plants will flower in *July*, and in *Auguſt* the Seeds will ripen, when the Plants will ſoon after decay.

GOOSEBERRY. *Vide* Groſſularia.

GORZ. *Vide* Geniſta Spinoſa.

GOSSYPIUM. *Vide* Xylon.

GRAFTING: In order to *Grafting*, you ſhould be provided with theſe Tools following:

1. A neat ſmall Hand-ſaw, to cut off the Heads of large Stocks.
2. A good ſtrong Knife with a thick Back, to make Clefts in the Stocks.
3. A ſharp Penknife, to cut the *Grafts*.
4. A *Grafting* Chiſſel, and a ſmall Mallet.
5. Baſs Strings, or woollen Yarn, to tie the *Grafts* with; and ſuch other Inſtruments and Materials as you ſhall find neceſſary, according to the Manner of *Grafting* you are to perform.
6. A Quantity of Clay, which ſhould be prepared a Month before it is uſed, and kept turn'd and mixed, like Morter, every other Day; which is to be made after the following Manner:

Get a Quantity of ſtrong fat Loam (in proportion to the Quantity of Trees intended to be grafted); then take ſome new Stone-horſe Dung, and break it in amongſt the Loam, and if you cut a little Straw or Hay very ſmall, and mix amongſt it, the Loam will hold together the better; and if there be a Quantity of Salt added, it will prevent the Clay from dividing in dry Weather; theſe muſt be well ſtirred together, putting Water to them after the Manner of making Morter: It ſhould be hollow'd like a Diſh, and fill'd with Water, and kept every other Day ſtirr'd: But it ought to be remember'd, that it ſhould not be expoſed to the Froſt, or drying Winds; and that the oftener it is ſtirred and wrought, the better.

There are ſeveral Ways of *Grafting*, the principal of which are Four.

1. *Grafting in the Rind*, call'd alſo *Shoulder Grafting*, which is only proper for large Trees: This is call'd *Crown Grafting*, becauſe the *Grafts* are ſet in form of a Circle or Crown, and is generally perform'd about the latter End of *March*, or the Beginning of *April*.
2. *Cleft-grafting*, which is alſo call'd *Stock* or *Slit Grafting*: This is proper for Trees or Stocks of a leſſer Size, from an Inch to two Inches or more Diameter: This *Grafting* is to be perform'd in the Months of *February* and *March*, and ſupplies the Failure of the Eſcutcheon-way, which is practiſed in *June*, *July*, and *Auguſt*.
3. *Whip-grafting*, which is alſo call'd *Tongue-grafting*: This is proper for ſmall Stocks of an Inch, half an Inch, or leſs, Diameter; this is the moſt effectual Way of any, and that which is moſt in Uſe.
4. *Grafting by Approach*, or *Ablactation*: This is to be perform'd when the Stock you would *graft* on, and the Tree from which you take your *Graft*, ſtand ſo near together, that they may be join'd: This is to be perform'd in the Month of *April*, and is alſo call'd *Inarching*, and is chiefly uſed for *Jaſmines*, *Oranges*, and other tender exotick Trees.

The Manner of performing theſe ſeveral Sorts of *grafting* being ſo generally known, and they having been ſo often deſcribed in the various Books of *Husbandry* and *Gardening*, it will be needleſs to repeat any Thing more on that Head in this Place: I ſhall only take notice in general of the ſeveral Sorts of Trees which will grow when grafted upon each other.

All ſuch Trees as are of the ſame Tribe, *i. e.* which agree in their Flower and Fruit, will take upon each other: For Inſtance; all the *Nut-bearing* Trees may be ſafely *grafted* on each other; as may all the *Plum-bearing* Trees, under which Head I reckon not only the ſeveral Sorts of *Plums*, but alſo the *Almond*, *Peach*, *Nectarine*, *Apricot*, &c. which agree exactly in their general Characters, by which they are diſtinguiſhed from all other Trees: But as theſe are very ſubject to emit large Quantities of Gum from ſuch Parts of the Trees as are deeply cut and wounded; which, in the tender Trees of this Kind, as it is more common and hurtful, ſo it is found to be the ſureſt Method to *bud* or *inoculate* theſe Sorts of Fruits, Vide *Inoculation*.

Then all ſuch Trees as bear Cones will do well upon each other, tho' they may differ in one being ever green, and the other ſhedding its Leaves in Winter; as is obſervable in the *Cedar of Libanus*, and the *Larch-tree*, which are found to ſucceed upon each other very well: But theſe muſt be grafted by Approach; for they abound with a great Quantity of Reſin, which is apt to evaporate from the *Graft*, if ſeparated from the Tree before it be join'd with the Stock, whereby they are often deſtroy'd; as alſo the Laurel on the Cherry, or the Cherry on the Laurel. All the Maſt-bearing Trees will alſo take upon each other; and thoſe which have a tender ſoft Wood will do well if grafted in the common Way; but thoſe that are of a more firm Contexture, and are ſlow Growers, ſhould be grafted by Approach.

By ſtrictly obſerving this Rule, we ſhall ſeldom miſcarry, provided the Operation be rightly perform'd, and at a proper Seaſon, unleſs the Weather ſhould prove very bad, as it ſometimes happens, whereby whole Quarters of Fruit Trees miſcarry; and it is by this Method that many Kinds of Exotick Trees are not only propagated, but alſo render'd hardy enough to endure the Cold of our Climate in the open Air; for being grafted upon Stocks of the ſame Sort which are hardy, the *Grafts* are render'd more capable to endure the Cold; as hath been experienced in moſt of our valuable Fruits now in *England*, which were formerly tranſplanted hither from more Southerly Climates, and were at firſt too impatient of our Cold to ſucceed well abroad, but have been, by Budding or Grafting upon more hardy Trees, render'd capable of reſiſting our ſevereſt Cold.

And theſe different *Graftings* ſeem to have been greatly in Uſe among the Ancients; tho' they were certainly miſtaken in the ſeveral Sorts of Fruits which they mention to have ſucceeded upon each other, as the *Fig* upon the *Mulberry*, the *Plum* upon the *Cheſnut*, with many others of the like Kind; ſome of which I have already try'd, and find them all Miſtakes, or at leaſt they did not mean the ſame Plants which at preſent are call'd by thoſe Names: Tho' I can't help thinking we are apt to pay too much Deference to the Writings of the Ancients, in ſuppoſing them ſeldom to be miſtaken, or to aſſert a Falſhood: Whereas, if their Works are carefully examin'd, it will be found that they often copy'd from each other's Writings, without making Experiments to prove the Truth of their Aſſertions: And it is well known, that the Ranging of Plants before *Cæſalpinus*'s Time (which is but about 150 Years ſince) was, by their outward Appearance, or from the ſuppoſed Virtues of them: Which Method is now juſtly exploded; and it hath been obſerv'd, from many repeated Trials, that however Plants may reſemble each other in the Shape and Make of their Leaves, Manner of Shooting, *&c.* unleſs they agree in their Manner of Fruiting, and their other diſtinctive Characters, they will not grow upon each other, tho' grafted with ever ſo much Art.

Of late Years ſome Perſons have made uſe of another Compoſition for Grafting, which they have found to anſwer the Intention of keeping out the Air, better than the Clay preſcribed above. This is compoſed of Turpentine, Bees-wax and Roſin melted together; this, when of a proper Conſiſtence, may be put on the Stock round the Graft, in the ſame Manner as the Clay is uſually applied; and tho' it be not above a quarter of an Inch thick, yet will keep out the Air more effectually than the Clay; and as Cold will harden this, ſo there is no Danger of its being hurt by Froſt, which is very apt to cauſe the Clay to cleave, and ſometimes fall off; and when the Heat of Summer comes on, this Mixture will melt and fall off without any Trouble. In uſing of this, there ſhould be a Tin or Copper-pot, with Conveniency under it to keep a very gentle Fire with Small-coal, otherwiſe the Cold will ſoon condenſe the Mixture; but you muſt be careful not to apply it too hot, leſt you injure the Graft. A Perſon who is a little accuſtomed to this Compoſition, will apply it very faſt, and it is much eaſier for him than Clay, eſpecially if the Seaſon is cold.

GRAMEN. Graſs.

The *Species* are;

1. Gramen *loliaceum, anguſtiore folio & ſpica. C. B. P.* Red Darnel Graſs, or Rey Graſs.
2. Gramen *pratenſe minus ſeu vulgatiſſimum. Raii Syn.* The moſt common Meadow Graſs.
3. Gramen *pratenſe paniculatum medium. Raii Syn.* The middle Sort of Meadow Graſs.
4. Gramen *pratenſe paniculatum majus, latiore folio. C. B. P.* The greateſt Meadow Graſs.
5. Gramen *ſecalinum. Ger. Emac.* Tall Meadow Rie Graſs.
6. Gramen *ſecalinum & ſecale ſylveſtre. Ger. Emac.* Wild Rie, or Rie Graſs.
7. Gramen *ſecalinum majus ſylvaticum. Hiſt. Oxon.* Greatwood Rie Graſs.
8. Gramen *paniceum, ſpica ſimplici lævi. Raii Syn.* Panic Graſs, with a ſingle ſmooth Ear.
9. Gramen *paniceum, ſpica diviſa. C. B. P.* Panic Graſs, with a divided Spike.
10. Gramen *paniceum, ſpica aſpera. C. B. P.* Rough-eared Panic Graſs.
11. Gramen *loliaceum, ſpica longiore. C. B. P.* Darnel.
12. Gramen *avenaceum dumetorum ſpicatum. Raii Syn.* Spiked-hedge Oat Graſs.
13. Gramen *avenaceum pratenſe. Park.* Meadow Oaten Graſs.
14. Gramen *avenaceum ſupinum arvenſe. Park.* Low Meadow Oaten Graſs.
15. Garmen *miliaceum vulgare. Park.* Common Millet Graſs.
16. Gramen *ſpicatum, ſemine miliaceo albo. Tourn.* Common Canary Graſs.
17. Gramen *ſpicatum, ſemine miliaceo nigro. Tourn.* Black Canary Graſs.
18. Gramen *ſpicatum, ſemine miliaceo minore nigro. Tourn.* Leſſer black Canary Seed.
19. Gramen *ſpicatum, ſemine miliaceo griſeo. Tourn.* Grey Canary Seed.
20. Gramen *paniculatum, locuſtis maximis candicantibus tremulis. Tourn.* The greateſt Quaking Graſs, with white Panicles.
21. Gramen *paniculatum, locuſtis maximis phœniceis tremulis. Tourn.* The greateſt Quaking Graſs, with ſcarlet Panicles.
22. Gramen *tremulum medium. Park.* The middle Quaking Graſs.
23. Gramen *tremulum minus, panicula parva. Park.* Smaller Quaking Graſs, with a ſmall Panicle.
24. Gramen *murorum ſpica longiſſima. Ger. Emac.* Capons-tail Graſs.
25. Gramen *dactylon, latiore folio. C. B. P.* Broad-leav'd Cocks-foot Graſs.
26. Gramen *dactyloides, radice repente. Ger. Emac.* Creeping Cocks-foot Graſs.
27. Gramen *typhinum majus ſeu primum. Ger. Emac.* Greateſt Cats-tail Graſs.
28. Gramen *typhinum minus. Ger.* Leſſer Cats-tail Graſs.
29. Gramen *criſtatum. J. B.* Smooth-creſted Graſs.
30. Gramen *ſpica triticea, repens vulgare, caninum dictum. Raii Syn.* Common Dogs Graſs, or Quick Graſs, or Couch Graſs.
31. Gramen *alopecuroides majus. Ger. Emac.* Common Fox-tail Graſs.
32. Gramen *alopecuroides minus. Park.* Smaller Fox-tail Graſs.
33. Gramen *ſpicatum, durioribus & craſſioribus locuſtis, ſpica brevi. Tourn.* French Haver Graſs.
34. Gramen *ſpicatum, durioribus & craſſioribus locuſtis, ſpica longiſſima. Tourn.* French Haver Graſs, with a long Spike.
35. Gramen *paniculatum, ſpicis craſſioribus & brevioribus variegatum. Tourn.* Striped Graſs.

The fourteen firſt-mentioned Sorts grow pretty common in the Paſtures in moſt Parts of *England*, and are often intermixed in the ſame Paſture; ſo that it is very rare to meet with a Paſture, which hath not ten or twelve Sorts of Graſs in it; but the Sort which is generally ſown about *London*, is the *Rey Graſs*, which is very hardy, and will grow on cold ſour Land better than moſt other Sorts; but as it ſeldom happens that the Seed is ſaved intire, without a Mixture of other Graſs Seeds, ſo it is very rare to meet with a Paſture, which has not many Sorts in it.

The beſt Seaſon for ſowing of Graſs Seed, is, the latter End of *Auguſt*, and the Beginning of *September*, that the Graſs may be well rooted before the Froſt ſets in, which is apt to turn the Plants out of the Ground, when they are not well rooted. This Seed ſhould be ſown in moiſt Weather, or when there is a Proſpect of Showers, which will ſoon bring the Graſs up; for the Earth being at that Seaſon warm, the Moiſture will cauſe the Seeds to vegetate in a few Days.

The Land on which Graſs-ſeed is intended to be ſown, ſhould be well ploughed and cleared from the Roots of noxious Weeds, ſuch as *Couch Graſs*, *Fern*, *Ruſhes*, *Heath*, *Gorſe*, *Broom*, *Reſt-Harrow*, &c. which if left in the Ground, will ſoon get the better of the Graſs, and over-run the Land. Therefore in ſuch Places where either of theſe Weeds abound, it will be a good Method to plough up the Surface in *April*, and let it lie ſome time to dry, then lay it in ſmall Heaps, and burn it; the Aſhes ſo produced, when ſpread on the Land, will be a good Manure for it: the Method of burning the Land, is particularly directed under the Article *Land*, which ſee; eſpecially if it is a cold ſtiff Soil. But where *Couch Graſs*, *Fern* or *Reſt Harrow* is in Plenty, whoſe Roots run far under Ground, the Land muſt be ploughed two or three times pretty deep in dry Weather, and the Roots carefully harrowed off after each ploughing; which is the moſt ſure Method to deſtroy them. Where the Land is very low, and of a ſtiff clayey Nature, which holds Water in Winter, it will be of ſingular Service to make ſome under-ground Drains, to carry off the Wet; which if detained too long on the Ground, will render the Graſs ſour. The Method of making theſe Drains are preſcribed under the Article *Land*; which ſee.

Before the Seed is ſown, the Surface of the Ground ſhould be made level and fine, otherwiſe the Seed will be buried unequal. The Quantity of Graſs-ſeed for an Acre of Land, is uſually three Buſhels; when the Seed is ſown, it muſt be gently harrowed in, and the Ground rolled with a wooden Roller; which will make the Surface even, and prevent the Seeds being blown in Patches. When the Graſs comes up, if there ſhould be any bare Spots, where the Seed has not grown, they may be ſown again, and the Ground rolled, which will fix the Seeds; and the firſt kindly Showers will bring up the Graſs, and make it very thick.

Some People mix *Clover* and *Rey Graſs* Seeds together, allowing ten Pounds of *Clover*, and one Buſhel of *Rey Graſs* to an Acre: but this is only to be done where the Land is deſigned to remain but three or four Years in Paſture, becauſe neither of theſe Kinds are of long Duration; ſo that where the Land is deſigned to be laid down for many Years, it will be proper to ſow the Graſs-ſeeds by themſelves, and not to mix either *Trefoil* or *Clover* amongſt them.

The following Spring, if there ſhould be any *Thiſtles*, *Ragwort*, or ſuch other troubleſome Weeds, come up among the Graſs, they ſhould be carefully cut up with a Spaddle before they grow large; and this ſhould be repeated two or three times in the Summer, which will effectually deſtroy them; for if theſe Plants are ſuffered to ripen their Seeds, they will be blown all over the Ground, their Seeds having Down adhering to them, which aſſiſts their Tranſportation; ſo that they are often carried by the Wind to a great Diſtance, and thereby become very troubleſome Weeds to the Graſs. For want of this Care, how many Paſtures may be ſeen almoſt over-run with theſe Weeds, (eſpecially the *Ragwort*,) when a ſmall Expence, if applied in time, would have intirely extirpated them! For a Man may go over ſeveral Acres of Land in one Day with a Spaddle, and cut up the Weeds juſt below the Surface of the Ground, turning their Roots upward; which if done in dry Weather, they will ſoon decay; but this muſt always be performed before the Plants come to have their Seeds formed, becauſe after that, many Sorts will live long enough to nouriſh their Seeds after they are cut, ſo as to ripen them; when there will be a Supply of Weeds for ſome Years after, which cannot be extirpated without a much greater Expence.

The *Panic* Graſſes are harſher than the common Meadow Graſſes, ſo are rarely cultivated in *England*; for the Cattle do not care to feed on them, where they have any other Fodder; and as they are annual, ſo, if they were equally good, they would not be worth cultivating; for theſe Plants which require an annual Culture, are too expenſive to be worth the Farmer's Care.

The *Canary* Graſſes, are ſown in ſome Parts of *England*, for their Seeds, which are uſed to feed Birds; the white Sort is generally preferred to the other, but the grey Sort is frequently intermixed with it. Theſe Seeds ſhould be ſown the Beginning of *March*, on a moderate light Soil; for they do not thrive well on ſtrong cold Land. The Surface of the Ground ſhould be well ſtirred, and made even, before the Seeds are ſown, that they may be equally buried. Three Buſhels of this Seed are ſufficient for an Acre of Land; when the Seed is ſown, which ſhould be done in dry Weather, the Ground muſt be gently harrowed to bury the Seeds, and then the Whole ſhould be rolled with a wooden Roller; which will ſmooth the Surface of the Ground, and prevent the Seeds from being removed by ſtrong Winds. When the Graſs is come up, if there ſhould be any rank Weeds amongſt it, they muſt be cut up with a Spaddle, as was before directed; for if they are permitted to grow, they will do great Damage to the Graſs. The latter End of *July*, or the Beginning of *Auguſt*, the Seeds will ripen, when it ſhould be cut, and as ſoon as it is dry, ſhould be threſhed out, or ſtacked; for if it remains abroad, the Birds will devour it: if the Crop ſucceeds, there will be upward of four Quarters on an Acre of Land.

The four Sorts of *Quaking Graſs*, are rather eſteemed as Curioſities, than for any real Uſe, ſo are ſometimes allowed a Place in Gardens; theſe produce light ſcaly Heads on ſlender Foot-ſtalks, which are moved by every Wind, after the Manner of the Leaves of the *Aſpen-tree*; from whence it had the Name of *Quaking Graſs*, or in ſome Places *Cow-quakes*, or in other Places *Ladies-hair*. Theſe Sorts are commonly in Head in *May*, which occaſioned this old *Engliſh* Proverb; May, *come ſhe early, come ſhe late, makes the Cow quake*. The middle Sort of Quaking Graſs grows very common in ſeveral Parts of *England*. The ſmaller Sort grows wild in the Iſland of *Jerſey*; but the greateſt Sort is not a Native of *England*, ſo is only to be found in ſome curious Gardens, where it is preſerved for the ſake of Variety.

The *Capons-tail Graſs* is found growing by the Path-ſides, and on Mud-walls, in ſeveral Parts of *England*, but is never cultivated for Uſe; this produces very long Spikes, which bend downward with the Weight of the Seed when it is near ripe; it is ſometimes preſerved in Gardens for Variety.

The two Sorts of *Cocksfoot Graſs*, are found upon ſandy Lands near the Sea in *Norfolk*, and the *Weſt* of *England*, but are ſeldom cultivated, being coarſe Sorts of Graſs, and never riſe above ſix or eight Inches high, ſo are unfit for making Hay. The only Uſe of either of theſe Graſſes is, for ſowing on looſe ſandy Lands, which will not produce any other Sort of Graſs; in which Places theſe will often thrive to Advantage; for as theſe ſpread cloſe to the Surface of the Ground, ſo they preſerve a Moiſture in the Earth, by the cloſe Growth of their Branches; and theſe Sorts will endure much more Drought, than moſt other Sorts of Graſs. Of this kind of Graſs, there are a great Number of Species in *America*, which are of great Uſe to the Inhabitants of the *Caribee Iſlands*; for ſome of them will thrive in the greateſt Drought, and afford uſeful Food for their Cattle, when moſt other Vegetables are burnt up. Some of theſe Sorts ſend forth Roots at every Joint, whereby they ſpread and propagate themſelves to a great Diſtance.

The two Sorts of *Cats-tail Graſs* are found plentifully by the Side of Paths, and in Corn-fields, in many Parts of *England*, as alſo in ſome Paſtures; but they are not profitable Graſſes to cultivate.

The *Couch Graſs* is one of the moſt troubleſome Weeds in Corn-lands and Gardens, and is with great Difficulty extirpated; for the Roots of this Kind run very far under Ground, and every ſmall Part of the Root will grow; ſo that if the Roots are torn into ſmall Pieces, every one of them will propagate where-ever they are left in the Ground. Where the Land is ſtocked with this Graſs, it ſhould be ploughed two or three Times in dry Weather, during the Heat of Summer; and after each Ploughing, the Ground ſhould be carefully harrowed, to draw the Roots out, which ſhould be drawn into Heaps, and then carted off the Ground; for if the Roots are left, they will ſtrike into the Ground after the firſt Shower of Rain, and ſoon become troubleſome: ſuch foul Land is very unfit to ſow with Grain; therefore it will be proper to ſow with *Turnips*, and *Beans* or *Peaſe*, which require hoeing two or three Times, which if done in very dry Weather, will be of great Uſe to deſtroy the Couch Graſs. Where this Method is not obſerved, it is common to ſee large Tracts of Land, which are ſown with Grain, ſo much over-run with Graſs, that many Times the Crop doth not produce ſo much Grain as was ſown on the Ground.

In Gardens this Graſs is much eaſier deſtroyed than in large Fields, becauſe the Ground being frequently dug, Care may be taken to pick out the Roots in digging; and if there be any left, and appear afterward, the Roots may be eaſily forked out; ſo that in one Year it may be deſtroyed, if proper Care be taken. But where the Ground is very full of the Roots of *Couch Graſs*, and the Land will admit of being trenched three Spits deep, that will be the moſt effectual Way of deſtroying it, and will be cheaper than picking out the Roots by Hand; for by trenching of the Ground ſo deep, the *Couch* will be buried near two Feet, which will rot it; and turning of the Ground ſo deep, will be moreover of great Service to it.

This Sort of Graſs, is what the *College of Phyſicians* have ordered to be uſed in Medicine; ſo that whenever Graſs is preſcribed, this is what is meant.

The *Fox-tail Graſſes* are frequently found in Paſtures intermixed with other Kinds, but are never ſown ſeparately. Theſe do very well for Fodder or Hay, and are uſeful Kinds of Graſs.

The *Bearded wild Oats*, or *Haver*, are frequently found amongſt Corn in ſeveral Parts of *England*, where ſometimes they become troubleſome Weeds; for if they are not drawn out of the Corn before it is ripe, it will be difficult to be ſeparated from the Corn in the Barn: But as they are annual Plants, ſo they may be eaſily deſtroyed with a little Care.

The *ſtriped Graſs* is preſerved in many Gardens for the Beauty of its variegated Leaves, which continue freſh the greateſt Part of the Year. This Sort is eaſily propagated by parting the Roots either in Spring or Autumn; for every Offſet will increaſe to be a large Root in one Year's Time. It will grow on any Soil, or in any Situation, ſo may be planted in any abject Part of the Garden where it will thrive, and afford an agreeable Variety. This Sort is by many Perſons called *Ribbon Graſs*, from the Stripes of White and Green, which run the whole Length of the Blade, like the Stripes in ſome Ribbons.

For the farther Management of Graſs, ſee *Paſture*, and *Meadow*.

GRANADILLA [is a Diminutive of *Granada*, or rather *Granata*, having many *Grains* or *Kernels*; becauſe the Fruit of this Plant is full of Seeds. It is alſo call'd the *Paſſion-Flower*; becauſe, if Allowance be given to Imagination, it exhibits all the Inſtruments of our Saviour's Paſſion] Paſſion-Flower.

The *Characters* are;

It hath a double Calyx, the firſt conſiſting of three Leaves, the other of five Leaves, which expand in Form of a Star: The Flowers conſiſt of five Leaves each, and are of a roſaceous Form: In the Center of the Flower ariſes the Pointal, with a Crown fringed at the Bottom, but furniſh'd with a tender Embryo at the Top, on which ſtand three Clubs, under which are the Stamina with rough, obtuſe Apices, which always incline downwards: The Embry turns to an oval or globular Fruit, fleſhy, and conſiſting of one Cell, which is full of Seeds adhering to the Sides, and cover'd with a Sort of Hood or Veil.

The *Species* are;

1. GRANADILLA *pentaphyllos, latioribus foliis, flore cæruleo magno. Boerh. Ind.* Common or broad-leav'd Paſſion-Flower.

2. GRANADILLA *pentaphyllos, anguſtioribus foliis, flore cæruleo magno.* Narrow-leav'd Paſſion-Flower.

3. GRANADILLA *pentaphyllos, anguſtioribus foliis, flore minore pallido cæruleo ſerotino.* Late narrow-leav'd Paſſion-Flower, with a leſſer and paler Flower.

4. GRANADILLA *Hiſpanis, Flos Paſſionis Italis. Col. in Recch.* Three-leav'd Paſſion-Flower.

5. GRANADILLA *folio tricuſpide, flore parvo flaveſcente. Tourn.* Paſſion-Flower with a three-pointed Leaf, and a ſmall yellowiſh Flower.

6. GRANADILLA *flore albo, fructu reticulato. Boerh. Ind.* White Paſſion-Flower, with a netted Fruit.

7. GRANADILLA *fœtida, folio tricuſpide villoſo, flore purpureo variegato. Tourn.* Stinking Paſſion-Flower, with a three-pointed hairy Leaf, and a purple variegated Flower, *call'd by the Inhabitants of* Barbados, Love in a Miſt.

8. GRANADILLA *fructu citriformi, foliis oblongis. Tourn.* Paſſion-Flower, with a Fruit ſhap'd like a Citron, and an oblong Leaf, *call'd by the Inhabitants of* Barbados, Water-Lemon.

9. Granadilla *latifolia, fructu maliformi.* Broad-leav'd Paſſion-Flower, with an Apple-ſhap'd Fruit.

10. Granadilla *flore ſuave-rubente, folio bicorni. Tourn.* Paſſion-Flower, with a Leaf divided into two Horns, and a ſoft red Flower.

11. Granadilla *folio amplo tricuſpidi, fructu Olivæ forma. Tourn.* Paſſion-Flower, with a three-pointed Leaf, and an Olive-ſhap'd Fruit.

12. Granadilla *folio anguſto tricuſpidi, fructu Olivæ forma. Tourn.* Paſſion-Flower, with a narrow three-pointed Leaf, and an Olive-ſhap'd Fruit.

13. Granadilla *Androſæmi folio, fructu Jujubino. Tourn.* Paſſion-Flower, with a Tutſan Leaf, and a Fruit like the Jujube.

14. Granadilla *folio haſtato, flore cæruleo majore. Houſt.* Paſſion-Flower with a ſpear-pointed Leaf, and a large blue Flower.

15. Granadilla *folio oblongo ſerrato, flore purpureo. Houſt.* Paſſion-Flower with an oblong ſerrated Leaf, and a purple Flower.

16. Granadilla *folio glabro, tricuſpidi, & anguſto, flore vireſcenti minimo. Tourn.* Paſſion-Flower, with a narrow ſmooth three-pointed Leaf, and a ſmall greeniſh Flower.

17. Granadilla, *quæ* Coanenepilli, *ſeu* Contrayerva *Hernand. Houſt.* Paſſion-Flower, or Contrayerva of *Hernandez.*

The firſt Sort here mentioned is the moſt common in all the *Engliſh* Gardens, and (notwithſtanding what Mr. *Bradley* has affirm'd) is very different from the ſecond and third Sorts. Nor did I ever ſee any Fruit upon this Kind, tho' planted in many different Soils and Situations; whereas the ſecond Sort rarely fails to produce Fruit every Year; and in order to obſerve the Truth of this, I planted one of each Kind in the ſame Soil and Situation, where the ſecond Sort has produc'd Fruit every Year ſince, but the firſt has not as yet ſhewn any Appearance thereof. The ſecond Sort does alſo differ in the Colour of the Flower, which is ſomewhat paler than the firſt, and the Petals are not quite ſo blunt at their Extremities.

The third Sort has very narrow Leaves, and the young Branches are of a purpliſh Colour; it is a very great Shooter, but does not flower until the latter End of Summer: The Flowers of this Kind are ſmaller, and of a paler Colour than either of the former. There is alſo a Variety in this Plant with yellow blotch'd Leaves, which ſome People preſerve as a great Curioſity; but as this Variegation is but ſmall, and hardly to be ſeen in vigorous Shoots, ſo it is ſcarce worth mentioning.

Theſe three Sorts are extreme hardy, and will endure our ſevereſt Cold in the open Air; tho' in very hard Winters their Shoots are ſubject to be kill'd, and ſometimes their whole Stems quite to the Surface: Yet it rarely happens that it deſtroys the whole Plant; for if the Roots are permitted to continue undiſturb'd, they ſeldom fail to ſhoot up again in the ſucceeding Summer.

Theſe are propagated by laying down their Branches, which in one Year's Time will take good Roots, and may then be remov'd to the Places where they are deſign'd to remain: The beſt Seaſon for tranſplanting theſe Plants, is towards the latter End of *March*, or the Beginning of *April*, juſt before they begin to ſhoot; for if they are remov'd earlier, and it ſhould prove dry froſty Weather, with cold North Eaſt Winds, (as it often happens in *March*) theſe Plants will ſcarcely endure it, which is the Occaſion of the Death of ſo many of them, as is often obſerv'd upon Tranſplantation.

The Plants ſhould be planted againſt a Wall or other Building, which ſhould face the South-Eaſt or South-Weſt; or elſe intermix'd amongſt flowering Shrubs in Quarters; where, if they are regularly train'd up to Poles, they will flower extremely well, and have a very good Effect in diverſifying ſuch Plantations. The beſt Seaſon for pruning of theſe Plants is in the Spring, after the cold Weather is paſt; for if they are prun'd very early, and it ſhould happen to be froſty Weather afterwards, it would endanger moſt of the young Branches; therefore it is much the better Way to let the whole Plant remain untouch'd (ſuffering the rude Part to hang down before the Stem and Branches) during the Winter Seaſon, which will be of Service in protecting them from the Severity of the Cold; and if at *Michaelmas* you lay a little Dung or other Mulch about a Foot thick upon the Surface of the Ground near the Stems, it will effectually guard their Roots from Froſt; which Method ſhould be conſtantly practis'd with ſuch as are planted in open Quarters. The Manner of Pruning is nothing more than to cut off all the ſmall weak Shoots, and ſhorten the ſtrong ones to about three Feet in Length: Or, if the Building is high againſt which they are planted, they may be left much longer, tho' you ſhould be careful not to have them too long; for as they are vigorous growing Plants, ſo they will ſoon get above the Building, and become troubleſome. Thoſe that are planted in Quarters, and train'd to Stakes, muſt be cut ſhorter, in order to have the Flowers nearer the Ground: Theſe, when their Seaſon for flowering is paſt, ſhould have a little Mulch laid about their Roots, and then their Stakes may be taken away, ſuffering their Banches to lie upon the Ground, which will alſo be of Service to protect the Plants from the Injuries of the Winter; and in the Beginning of *April* they may be trimmed and ſtaked up again: And when the Plants begin to ſhoot, they ſhould conſtantly be kept train'd up to the Stakes, whereby they will not only appear handſome, but the Place will be clearer to work in, as alſo to paſs thro'.

The Fruit bearing Kind may alſo be propagated by ſowing of the Seeds in the Spring of the Year, in Pots fill'd with light rich Earth, which ſhould be plung'd into a moderate Hot-bed, to facilitate the Growth of the Seeds; and when the Plants are come up, you muſt harden them by Degrees to bear the open Air: In theſe Pots they ſhould remain until the ſucceeding Spring, obſerving to ſhelter them in Winter under a Frame, or elſe place the Pots into the Earth under a warm Wall, to prevent their Roots from freezing thro' the Pots; and the Beginning of *April* you may ſhake them out of the Pots, and divide the Plants from each other, planting them in the Places where they are deſign'd to remain; or, if you have not the Ground ready, they may be put each into a ſeparate Pot, ſo that they may, at any Time, be turn'd out into the Ground, without diſturbing their Roots; for they are difficult Plants to remove when old.

Theſe Plants may alſo be planted to cover Arbors of Seats in warm ſituated Places, where they will flower extremely well, and anſwer the purpoſes of thoſe Arbors, as well as any other Plants which are at preſent made uſe of.

The fourth Sort is ſomewhat tenderer than any of the former: This dies to the Surface every Winter, and riſes again the ſucceeding Spring, and, if the Summer be warm, will produce large Quantities of Flowers, which are near as large as the common Sort, but the Petals of the Flower are narrower, and ſtriped with Purple. This is the firſt Sort of *Paſſion-Flower* which we find deſcrib'd in old botanick Authors, and is what *Parkinſon* has figur'd and deſcrib'd in his *Flower-Garden*; but ſince the other Sorts have been brought into *Europe*, they have ſo much prevail'd, that this laſt mention'd is rarely to be found, except in ſome few curious Gardens. This may be increas'd by parting of the Roots, which ſhould be done the Beginning of *April*, and muſt be either planted into Pots fill'd with light rich Earth, or in a good warm Border under a South Wall, for it is ſubject to be deſtroy'd in very hard Weather. The Pots, wherein theſe Plants are ſet, may be plung'd into a gentle Hot-bed, in order to promote their taking Root, it being ſomewhat difficult in rooting after it is remov'd; and this will promote its flowering, provided you do not draw it too much: And by this Means alſo you may propagate the Plant; for, when it has made pretty ſtrong Shoots, if you lay them down, and apply a gentle Warmth to the Pots, they will puſh out Roots in two or three Months Time fit for tranſplanting, which, if done before the cold Weather comes on in Autumn, they will be ſettled ſo as to endure the Winter.

The Seeds of this Plant are many Times brought over from *America*, (where the Plant grows in great Plenty) which, when obtain'd, may be ſown in a moderate Hot-bed in the Spring, and treated as was before directed for the common Sort, with this Difference, *viz.* that this being more tender, ſhould not be expos'd to the open Air ſo ſoon; and, in Winter, the Pots ſhould be plung'd into an old Bed of Tanners-bark, which has loſt moſt of its Heat, and it ſhould be covered with Glaſſes and Mats in very bad Weather, but, when it is mild, they ſhould have as much open Air as poſſible; you muſt alſo obſerve not to give them much Water in Winter.

The fifth Sort dies to the Ground every Year, as the laſt, and riſes again the ſucceeding Spring: This is very hardy, enduring our ſevereſt Cold in the open Ground, and increaſes very faſt by its ſpreading Roots; but this ſeldom produces Flowers with us, and when it doth, they are ſo ſmall and ill colour'd, that it ſcarce deſerves a Place in a Garden, except for adding to the Variety.

The ſixth Sort is an annual Plant with us, and requires to be rais'd upon a Hot-bed: The Seeds of this ſhould be ſow'd in *February* with *Amaranthus's*, &c. And when the Plants are come up, they ſhould be tranſplanted ſingly into ſmall Pots fill'd with light Earth, and plung'd into a freſh Hot-bed, to bring them forward; and, in a Month's Time after, (when the Bed will begin to loſe its Heat) you ſhould prepare a freſh Hot-bed; then ſhake the Plants out of the ſmall Pots, and put them into larger, obſerving to take off the Roots of the Plant which are matted round the Outſide of the Ball of Earth, being careful not to break too much of the Earth from the Roots: And after having plac'd the Plant exactly in the Middle of the larger Pot, you muſt fill the Pot with the like freſh light Earth, plunging the Pots into the new Bed, in which Place they may remain a Month longer, obſerving to water them as they ſhall require, as alſo to give them Air in proportion to the Heat of the Weather: And when their Roots have fill'd theſe Pots, they ſhould be taken out, and tranſplanted into larger, giving them a little Warmth to cauſe them to take freſh Root the ſooner; and after they are well rooted, you may remove them into the Stove, where they may be protected from the Cold of the Nights and great Rains; in which Situation they will produce great Numbers of Flowers, and ripen their Seed perfectly well. In Autumn they commonly decay, tho' I doubt not but they would continue longer, if they were plac'd in a good Stove, and preſerv'd with Care.

The ſeventh Sort is ſomewhat like the ſixth, but differs therefrom in the Shape of its Leaves, which, in the ſixth Sort, are large and narrow, but, in the ſeventh, broad and angular, approaching to the Shape of the white Briony, and are rougher, and of a ſtronger Scent: The Flowers alſo of this are ſtrip'd in the Middle with purple, whereas the others are all white; nor doth this Plant often produce its Flowers the firſt Year with us, but muſt be preſerv'd in a warm Stove thro' the Winter, and the following Summer it will produce Flowers and perfect its Seeds.

This Plant muſt be ſown on a Hot-bed in the Spring, and managed as was directed for the laſt, with this Difference only, *viz.* That as this ſeldom flowers the firſt Summer, ſo thoſe Plants which you intend to preſerve thro' the Winter, ſhould be train'd up to indure the open Air in the Summer, whereby they will be better able to live in Winter,

This is found in great Plenty in many Places in the *Weſt-Indies*, where the Inhabitants call it *Love in a Miſt.* The Seeds are frequently brought into *England* by that Name. *Pere Plumier* ſays, That he found it in great Plenty in the Hedges in the Iſland of *Martinico*, where he obſerv'd the Flowers conſtantly open'd before the riſing of the Sun, after which it ſeldom continued an Hour. He alſo ſays, That it continues flowering almoſt throughout the whole Year; but that the Birds, Lizards, and Ants are ſo fond of this Fruit, that it is very difficult to find them intire when ripe.

The eighth Sort is a durable Plant, growing woody, and is more arboreſcent than any other Species of this Plant which I have yet ſeen. The Seeds of this are often brought over from *Barbados*, where it is cultivated in the Gardens for the Goodneſs of its Fruit, altho' the Flowers (which are finer than thoſe of the common Sort) renders it worthy of a Place in a good Garden, had the Plant no other good Qualities to recommend it.

This Plant may be rais'd by ſowing the Seeds upon a Hot-bed, as was directed for the two other Sorts, and muſt be afterwards tranſplanted into Pots, and managed in the ſame manner; but this never produces its Flowers until the ſecond or third Year after ſowing, ſo it muſt be carefully preſerv'd in Winter in a warm Stove with other tender Plants which come from the ſame Country: but, in the Summer, it ſhould have a good Share of free Air, eſpecially in warm Weather, tho' it will not bear to be wholly expoſed to the open Air.

It may alſo be propagated by laying down ſome of its Branches in the Spring, which, in two Months Time, will ſtrike Root, and may then be tranſplanted into Pots, and managed as the old Plants. During the Summer-ſeaſon theſe Plants will require to be plentifully water'd, (eſpecially if they are kept warm) but in Winter they ſhould not have too much Wet; therefore you ſhould often refreſh them, but do not give them much at each Time. The Heat, in which they thrive beſt in Winter, is that mark'd *Piemento*, upon Mr. *Fowler*'s *Botanical Thermometers*; but in Summer they will require a much greater Share of Warmth.

I don't find any Authors, who have written on this Plant, mention its growing wild in any Parts of the *Weſt-Indies*. *Pere Plumier* ſays, It is cultivated in Gardens, to cover Arbours and Seats, for the Goodneſs of its Fruit, which ripens in *April* and *May*, and is of a wonderful refreſhing Nature, and is commonly uſed in Fevers as a Cordial Syrup, in the ſtead of *Rob of Gooſberries*. The *French* call the Fruit of this Plant *Pommes de Liane*; and the *Engliſh*, *Water Lemon*, as chiefly delighting to grow in a moiſt Soil. The Flowers of this Plant have a very agreeable Scent, and are extremely beautiful.

The ninth Sort alſo is an abiding Plant, but never becomes ſo woody as the former: The Stalks are commonly of a green herbaceous Colour: The Leaves are broader and ſhorter, but not ſo thick as thoſe of the former, and of a livelier green Colour: The Flowers of this Kind are very large, and of a fine red Colour, inclining to purple, and very ſweet: The Fruit is about the Size of a middling Apple, and of an agreeable Flavour.

This may alſo be propagated by Seeds or Layers, as the former Sort, and muſt be managed exactly in the ſame Manner; ſo that I ſhall not repeat here, but only obſerve, that this will alſo grow from Cuttings, if planted in a Hot-bed during any of the Summer Months.

Pere Plumier obſerv'd this Plant in the Iſle of St. *Domingo*: It flowers there in *April.*

The tenth Sort is very common in moſt Parts of the *Caribbee* Iſlands. I have alſo received Seeds of it from the *Babama* Iſlands, from which I have rais'd Plants of this Kind that have produced Flowers and Fruits in the *Phyſick-Garden* at *Chelſea*. It requires much the ſame Management as the two former Sorts, tho' I could never propagate this either by Cuttings or Layers. It requires a great Share of Water, eſpecially in the Summer-ſeaſon, without which it will rarely flower; but in Winter it muſt have it more ſparingly, tho' it will often require to be refreſh'd. This delights in the ſame Degree of Heat with the former.

The Flowers of this Plant are very ſmall, and of ſhort Duration; nor is there any great Beauty in the Plant, or any Thing valuable in its Fruit to recommend it: However, it may have a Place in great Collections of Plants, to add to the Variety.

The eleventh and twelfth Sorts I have had come up in the Earth, which came from the *Weſt-Indies*; but I have not as yet ſeen their Flowers: Theſe may be preſerv'd in the ſame Manner as the former, but delight to grow in a moiſt Soil, therefore muſt be often refreſh'd with Water. Neither of theſe do promiſe to be of long Continuance, tho' I am apt to believe they may be propagated by Layers.

The thirteenth Sort is alſo a perennial Plant, which is very common in divers Parts of the *Weſt-Indies*: The Flowers of this Kind are very ſmall, and of a greeniſh Colour, without Smell, and the Fruit is of a fine purple Colour, when ripe. It requires the ſame Management as the former, and may be propagated by laying down the Branches early in the Spring.

The Seeds of the four laſt Sorts of Paſſion-flowers were ſent from *La Vera Cruz*, by the late Dr. *William Houſtoun*; the fourteenth and fifteenth Sorts are new, and have not been mentioned by any Botanick Writer, before they were diſcovered by the Doctor. Since which time the fifteenth Sort has been figured and deſcribed by Mr. *John Martyn*, Profeſſor of Botany at *Cambridge*, in his fourth Decade of rare Plants. Theſe two Sorts produce very beautiful Flowers; and the fifteenth continues flowering near three Months, which renders it more valuable. The other two Sorts have little Beauty in their Flowers; ſo are only preſerved by thoſe who are curious in the Study of Botany. Theſe Plants are tender, and require to be placed in a Bark-ſtove: where they will climb to a great Height, and produce great Plenty of Flowers. There is now an Eſpalier in a very large Stove in the Phyſick-Garden, which is ſixteen Feet high, and covered over with theſe Kinds of Paſſion-flowers, which has a fine Effect. But as the Plants will ſoon root through theſe Pots into the Bark-bed, ſo, if they are diſturbed, it will greatly check their Growth; therefore they ſhould be permitted to remain in the Bark: Or if, in the firſt making of the Stove, a Border be taken out of the Pit (on the Back-ſide next the Flues) about two Feet wide, which may be boarded up with ſtrong Ship-plank, and this Border filled with Earth, into which theſe Plants may be planted; they may remain ſeveral Years undiſturbed in theſe Borders, and will make a fine Appearance. The Reaſon of my adviſing this Border to be divided from the Bark-pit with Boards, rather than by a Brick-wall, is, that the Heat of the Bark may more eaſily warm the Borders, which will be of great Service to the Plants.

Theſe four Sorts may be propagated from Seeds, which ſhould be ſown on a Bed in the Spring, and managed as hath been directed for the eighth, ninth, and tenth Sorts; to which the Reader is referred to avoid Repetition. They may be alſo propagated by laying down of the Branches, which will take Root in three or four Months; when they may be taken from the old Plants, and planted into Plants filled with rich Earth, and treated in the ſame Manner as the ſeeding Plants. Theſe Plants flower in *June*, *July*, and *Auguſt*, and ſometimes produce ripe Fruit in *England*.

As to what Mr. *Bradley* relates of his having ſeen above 30 different Kinds of this Plant in the *Phyſick-Garden* at *Amſterdam*, I cannot intirely rely upon it; for when I was there, at *Midſummer* 1727, I did not ſee a fourth-part of that

Number, when, if they had been there, they would, at that Seaſon, have appear'd; nor did I find their Stoves ſo contriv'd, as to be capable of maintaining ſome of the very tender Kinds; ſo that I am apt to think that Gentleman was miſtaken in his Account.

What hath been commonly related of this Flower's repreſenting the Crucifixion of our Saviour, is now too much exploded to need any Thing more to be ſaid in Confutation of it; ſince every one who has been at the Pains to examine the Flower, and the Stories related about it, has found it was a Fiction of the *Jeſuits*, who added many Things to the Figure they gave of it, and alter'd many that were really there, ſo as to make as lively a Repreſentation as poſſible of their own fictitious Account of it: But why ſuch Characters ſhould be ſtamp'd upon the Flowers of a Parcel of Plants, which were not known to grow in any other Part of the World but *America*, (which was not diſcover'd 'till many hundred Years after the Paſſion of our Saviour) they have not yet attempted to explain; tho', I think, it would be a Curioſity worth their Examination; ſince the Repreſentation of a Tranſaction, to a People who never heard any Thing of it, nor could have any Conception of the Matter, would be of very little Uſe to them: But this is beſide my Buſineſs, and therefore I ſhall leave this Matter to thoſe ſuperſtitious Perſons who can make a Miracle of every Thing that ſubſiſts in their Imaginations.

GRAPES. *Vide* Vitis.

GRASS: The *Engliſh Graſs* is of ſo good a Quality for *Walks* or *Graſs-plots*, that if they be kept in good Order, they have that exquiſite Beauty that they cannot come up to in *France*, and ſeveral other Countries.

But Green Walks and Green Plots are, for the moſt part, not made by ſowing the *Graſs* Seed, but by laying Turfs: And, indeed, the Turfs from a fine Common are much preferable to ſown *Graſs*.

In ſowing a fine Green Plot, there is a Difficulty in getting good Seed: It ought not to be ſuch as is taken out of a Hayloft without Diſtinction; for that Seed ſhooting too high, and making large Stalks, the lower part will be naked and bare; and altho' it be mow'd ever ſo often, it will never make handſome *Graſs*, but, on the contrary will come to nothing but Tufts of Weeds and *Quick-Graſs*, very little better than that of the common Fields.

If Walks or Plots be made by Sowing, the beſt way is to procure the Seed from thoſe Paſtures where the *Graſs* is naturally fine and clear, or elſe the Trouble of keeping of it from ſpiry and benty *Graſs* will be very great, and it will ſcarce ever look handſome.

In order to ſow *Graſs-ſeed*, the Ground muſt be firſt dug or broken up with a Spade; and when it has been dreſs'd and laid even, it muſt be very finely rak'd over, and all the Clods and Stones taken off, and cover'd over an Inch thick with good Mould to facilitate the Growth of the Seed: This being done, the Seed is to be ſown pretty thick, that it may come up cloſe, and ſhort; and it muſt be rak'd over again to bury and cover the Seed, that if the Weather ſhould happen to be windy, it may not be blown away,

As to the Seaſon of ſowing *Graſs*, the latter End of *Auguſt* is a good time; becauſe the Seed naturally requires nothing but Moiſture to make it grow: If it be not ſown till the latter End of *February*, or the Beginning of *March*, if the Weather proves dry, it will not ſo ſoon make the Walks or Quarters green. It is alſo beſt to ſow it in a mild Day, and inclining to Rain, for that, by ſinking down the Seed in the Earth, will cauſe it to ſhoot the ſooner.

After the Seed is well come up, and the *Graſs* is very thick, and of a beautiful Green, it will require a conſtant Care to keep it in Order: This conſiſts in mowing the *Graſs* often; for the oftener it is mowed, the thicker and handſomer it grows: It muſt alſo be roll'd with a Cylinder or Roller of Wood, to level it as much as poſſible.

If *Graſs* be neglected, it will run into *Quick-Graſs* and *Weeds*; and if it does ſo, there is no way to recover it, but either by ſowing it, or laying it over again, and that once in every two Years: But if the Ground be well clear'd from the Roots of ſtrong Weeds, and the Turf be taken from a fine level Common, it will continue handſome for ſeveral Years, provided it be well kept.

In order to keep *Graſs-plots* or *Walks* handſome and in good Order, in Autumn you may ſow ſome freſh Seed over any Places that are not well fill'd, or where the *Graſs* is dead, to renew and furniſh them again: But there is nothing which improves *Graſs* ſo much as conſtant rolling and polling of it, to deſtroy Worm-caſts, and thereby the Turf is rendred fine.

GRAVEL and *Graſs* are naturally Ornaments to a Country-Seat, and are the Glory of the *Engliſh* Gardens, and Things by which we excel all other Nations, as *France*, *Holland*, *Flanders*, &c.

There are different Sorts of *Gravel*; but, for thoſe who can conveniently have it, I approve of that *Gravel* on *Black Heath*, as preferable to moſt that we have in *England*, it conſiſting of ſmooth, even Pebbles, which, when mix'd with a due Quantity of Loam, will bind exceeding cloſe, and look very beautiful, and continue handſome longer than any other Sort of *Gravel* which I have yet ſeen.

Some recommend a Sort of Iron-mould *Gravel*, or *Gravel* with a little binding Lime amongſt it, than which nothing, they ſay, binds better when it is dry: But in wet Weather it is apt to ſtick to the Heels of one's Shoes, and will never appear handſome.

Sometimes Loam is mix'd with *Gravel* that is over-ſandy or ſharp, which muſt be very well blended together, and let lie in Heaps; after which it will bind like a Rock.

There are many Kinds of *Gravel* which do not bind, and thereby cauſe a continual Trouble of rolling, to little or no Purpoſe: As for ſuch,

If the *Gravel* be looſe or ſandy, you ſhould take one Load of ſtrong *Loam*, and two of *Gravel*, and ſo caſt them well together.

If it be an old Walk, that only wants coating over, it will be ſufficient to lay it two or three Inches thick: But where there is plenty of this ſtrong reddiſh Loam, then you may lay it the full Depth.

Some ſkreen the *Gravel* too fine; but this is an Error: If it be caſt into a round Heap, and the great Stones only raked off, it will be the better.

Some are apt to lay *Gravel-Walks* too round; but this is likewiſe an Error, becauſe they are not ſo good to walk upon, and beſides, it makes them look narrow; an Inch is enough in a Crown of five Feet; and it will be ſufficient, if a Walk be ten Feet wide, that it lies two Inches higher in the Middle than it does on each Side; if fifteen Feet, three Inches; if twenty Feet, four; and ſo in proportion.

For the Depth of *Gravel-Walks*, ſix or eight Inches may do well enough; but a Foot Thickneſs will be ſufficient for any.

The Month of *March* is the propereſt time for laying *Gravel*; it is not prudent to do it ſooner, or to lay Walks in any of the Winter Months before that time.

Some, indeed, turn up *Gravel-Walks* in Ridges in *December*, in order to kill the Weeds: But this is very wrong; for beſides that it deprives them of the Benefit of them all the Winter, it does not anſwer the End for which it is done, but rather the contrary; for tho' it does kill the Weeds for the preſent, yet it adds a Fertility to them as to the great future Increaſe of both them and Graſs.

If conſtant rolling them after the Rains and Froſt will not effectually kill the Weeds and Moſs, you ſhould turn the Walks in *April*, and lay them down at the ſame time.

In order to deſtroy Worms that ſpoil the Beauty of *Gravel* or Graſſy-Walks, ſome recommend the watering them well with Water in which Walnut-tree Leaves have been ſteep'd and made very bitter, eſpecially thoſe Places moſt annoy'd with them; and this, they ſay, as ſoon as it reaches them, will make them come out haſtily, ſo that they may be gather'd: But if, in the firſt laying of the Walks, there is a good Bed of Lime rubbiſh laid in the Bottom, it is the moſt effectual Method to keep out the Worms; for they don't care to harbour near Lime.

Grounds that are gravelly and ſandy eaſily admit both Heat and Moiſture: but they are not much the better for it; becauſe they let it paſs too ſoon, and ſo contract no Ligature; or elſe, if they have a clayey Bottom, they retain it too long, and by that means either parch or chill too much, and produce nothing but Moſs, or cancerous Infirmities: But if the Bottom be a *Gravel*, and there are two Feet of good Earth upon the Surface, it is preferable to moſt other Soils for almoſt any Sort of Fruit; for tho' this Soil will not produce the Fruits planted thereon ſo large as a loamy Soil, yet they will be much better-taſted, and earlier ripe.

GRAVITY, is by ſome call'd *Vis Centripeta*; and is that Quality by which all heavy Bodies tend towards the Center of the Earth, accelerating the Motion the nearer they move towards it.

Gravity is alſo defin'd more generally, the natural Tendency of one Body towards another; and by others, more generally ſtill, the mutual Tendency of each Body, and each Particle of a Body, towards all others; and in this Senſe it coincides with what is more uſually call'd *Attraction*.

The Terms *Gravity*, *Centripetal Force*, *Weight*, and *Attraction*, do, in effect, all denote the ſame Thing, only in different Views and Relations.

In Propriety, *Gravity*, *Force of Gravity*, or *Gravitating Force*, is, when we conſider a Body as tending towards the Earth.

Centripetal Force, is the ſame Force as the former, when we conſider it as immediately tending to the Centre of the Earth.

Attraction, or *Attractive Force*, is the ſame as the former, when we conſider the Earth or Body towards which it tends.

Weight, is the Name we give to it, when we conſider it in reſpect to an Obſtacle or Body, in the way of its Tendency upon which it acts.

It is a Law of Nature long obſerved, that all Bodies near the Earth have a *Gravity* or Tendency towards the Center of the Earth; which Law the Moderns, and the immortal Sir *Iſaac Newton*, have found, from certain Obſervations, to be much more extenſive, and to hold univerſally, with reſpect to all the known Bodies in Nature.

It is now therefore a Principle, or Law of Nature, that all Bodies, *and all the Particles of all Bodies*, gravitate *towards each other mutually*. From which ſingle Principle Sir *Iſaac Newton* has happily deduced all the great *Phænomena* of Nature.

There is a two-fold *Gravity* of all Bodies, conſidered within the Confines of any Fluid; viz. *True*, *abſolute* and *Apparent*, *Vulgar* or *Comparative*.

Abſolute Gravity, is the whole Force by which any Body tends downwards.

Vulgar, or *Relative Gravity*, is the Exceſs of *Gravity* in one Body above the *Specifick Gravity* of the Fluid, by which it tends downwards more than the ambient Fluid does.

As to *Abſolute Gravity*, the Parts of all Fluids, and all Bodies, do really *gravitate* in their proper Places, and, by their joint Weight, make the Weight of the Whole; for every heavy Whole is a heavy Body; and the Weight of any Whole is equal to the Weight of all its Parts, becauſe compounded of them.

The *Vulgar* or *Relative Gravity* is ſuch, that, in reference to it, Bodies do not *gravitate* in their Places; or rather, do not *pregravitate*, when compared with one another; but, by hindring one another in their mutual Endeavour to deſcend, do remain in their proper Places, as if they were not at all heavy.

People in common ſuppoſe, that thoſe Things which do not *pregravitate* in the Air, Water, *&c.* have no *Gravity* at all, and only conclude thoſe to be heavy Bodies, which they ſee *pregravitate* or deſcend, becauſe they cannot be borne up by the ordinary *Gravitation* of the Fluid, or by its Preſſure all manner of ways: So that, among the common People, the Notion of Weight is only the Exceſs of the Weight of any Body above that of Air; and thoſe Things are accounted light, which, becauſe they are leſs heavy than Air, are borne or buoy'd up by it: whereas thoſe Bodies comparatively light, are not really ſo; ſince it has been found by Experiment *in Vacuo*, that they deſcend as faſt as other Bodies do in Air.

The Properties of *Gravity* are as follow:

1ſt; That all Bodies do deſcend towards a Point, which is either the Centre of Magnitude of the Earth and Sea, about which the Sea Forms itſelf into a ſpherical Surface, or is very near it.

2dly; This Point or Centre is fixed within the Earth.

3dly; The Force of *Gravity* is nearly equal in all Places equidiſtant from the Centre of the Earth: But, indeed, all Places of the Surface of the Earth are not at equal Diſtance from the Centre; becauſe the Equatorial Parts are ſomething higher than the Polar Parts.

4thly; *Gravity* affects all Bodies equally, without regard either to their Bulk, Figure, or Matter; ſo that, abſtracting from the Reſiſtance of the Medium, the moſt compact and looſe, the greateſt and ſmalleſt Bodies would deſcend equal Spaces in equal Times, as appears from the Quickneſs of the Deſcent of very light Bodies in an exhauſted River.

Whence we may obſerve a very great Difference between *Gravity* and *Magnetiſm*; *Gravity* affecting all Bodies alike, and *Magnetiſm* affecting only Iron, and that towards its Poles.

And hence we may alſo conclude, that there is no poſitive *Levity*; for that thoſe Things which do ſeem to be light, are only ſo comparatively; and whereas ſeveral Things ſwim and riſe in Fluids, the Cauſe is only, becauſe they are not ſo heavy as thoſe Fluids, Bulk for Bulk.

There is no reaſon that Cork ſhould be ſaid to be light, becauſe it floats upon Water, more than Iron, by reaſon that will float on Mercury.

5thly; This Power increaſes in deſcending Bodies towards the Centre of the Earth, in proportion to the Squares of the Diſtances therefrom reciprocally; and alſo decreaſes in aſcending, in the ſame proportion, ſo as, at a double Diſtance, to have but a quarter of the Force, *&c.*

This appears very agreeable to Reaſon; becauſe the *gravitating* or attracting Power muſt of Neceſſity be excited more feebly in a greater Sphere, and more vigorouſly in a ſmall Sphere, in proportion as it is expanded or contracted.

So that the Surfaces of Spheres being to one another as the Squares of the *Radii*, the Power of them, at ſeveral Diſtances, will be reciprocally as the Squares of thoſe Diſtances; and then the whole of its Action upon each ſpherical Surface, whether it be great or ſmall, will be always equal.

6thly; As all Bodies gravitate towards the Earth, ſo does the Earth equally *gravitate* towards all Bodies; *i. e.* the Action of *Gravity* is mutual on each Side, and equal.

Hence alſo the attractive Powers of Bodies, at equal Diſtances from the Centre, as are the Quantities of Matter in the Bodies.

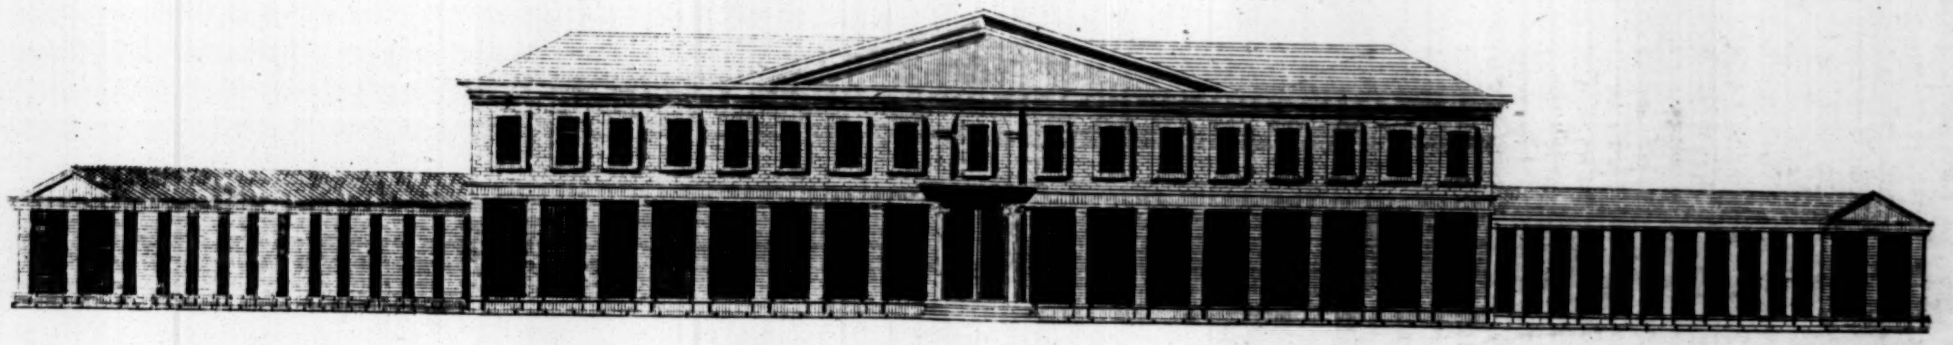
Hence alſo the attractive Force of intire Bodies conſiſts of the attractive Force of the Parts; for by the adding or taking away any Part of the Matter of a Body, its *Gravity* is increaſed or diminiſhed in proportion to the Quantity of ſuch Particles to the intire Maſs.

To this Property of *Gravity*, perhaps, is owing the alternate Motion of the Sap in Vegetables, which may be accounted for from the Alternacies of the Day and Night, Warm and Cold, Moiſt and Dry: For it is very probable that the Sap in Plants does, in ſome meaſure, recede from the Tops of their Branches, as the Sun leaves them; becauſe its rarefying Power then ceaſing, the greatly rarefied Sap, and Air mix'd with it, will condenſe and take up leſs Room than they did; and the Dew and Rain will then be ſtrongly imbibed by the Leaves, which mixing with the included Sap, will render it too heavy to be ſuſtained by the Preſſure of the Air upon the Surface of the Plant, or by any conſtricting Quality of the containing Veſſels, ſo that it recedes downwards until it meets with an equal Reſiſtance, whereby it is ſuſpended until the Return of Warmth, which rarefies the Sap, and renders it ſpecifically lighter than before, and ſo mounts again to the Extremity of the Branches; and part of it, by being rendered extremely light, paſſes off thro' the Pores of the Plant, and is evaporated.

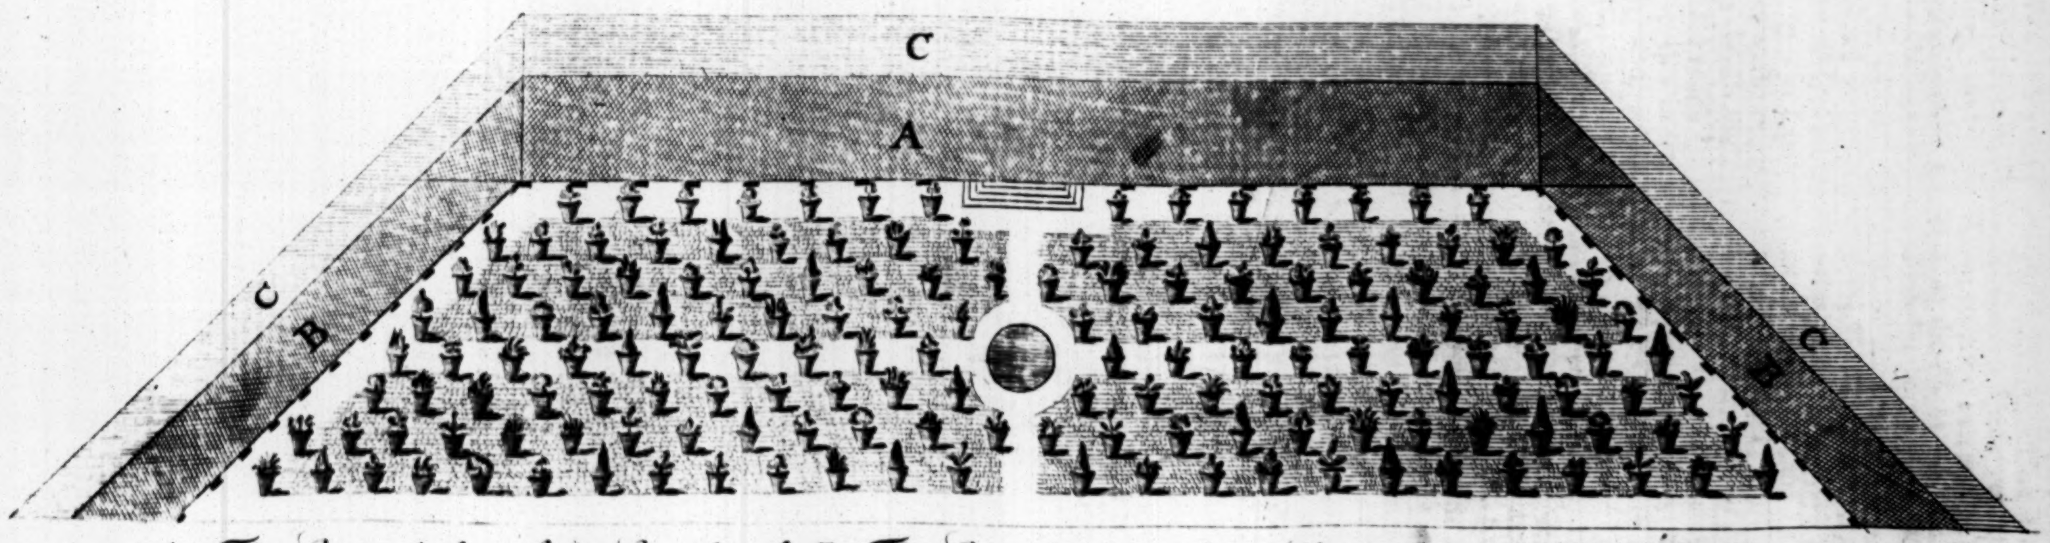
GREEN-HOUSE, *or* Conſervatory.

As of late Years there have been great Quantities of curious exotick Plants introduced into the *Engliſh* Gardens, ſo the Number of *Green-houſes* or *Conſervatories* has increaſed, and not only a greater Skill in the Management and Ordering of theſe Plants has increaſed therewith, but alſo a greater Knowledge of the Structure and Contrivance of theſe Places, ſo as to render them both uſeful and ornamental, hath been acquired: And ſince there are many Particulars to be obſerved in the Conſtruction of theſe *Houſes*, whereby they will be greatly improv'd, ſo I thought it neceſſary not only to give the beſt Inſtructions for this I was capable of, but alſo to give a Deſign of one in the Manner I would chuſe to erect it, upon the annexed Copper-Plate.

As to the Length of theſe Houſes, that muſt be proportion'd to the Number of Plants they are to contain, or the Fancy of the Owner; but their Depth ſhould never be greater than eighteen or twenty Feet in the Clear: And the Length of the Windows ſhould be at leaſt equal to the Depth of the Houſe; and if they are ſomewhat longer, it will be ſtill the better: Theſe Windows ſhould be carried up quite to the Ceiling, that there may be no Room for dead Air in the Upper Part of the Houſe; and they ſhould come down within about ten Inches, or a Foot of the Floor: Their Breadth ſhould be proportion'd to the Length of the Houſe, which, in a ſmall *Green-houſe*, may be four Feet broad; but in a large one, they ſhould be ſix Feet. The Piers between theſe Windows ſhould be as narrow as poſſible to ſupport the Building; for which Reaſon, I ſhould chuſe to have them of Stone, or of hard well-burn'd Bricks; for if they are built with fine rubb'd Bricks, thoſe are generally ſo ſoft, that the Piers will require to be made thicker, otherwiſe the Building will be in Danger of falling in a ſhort time, eſpecially if you have any Rooms over the *Green-houſe*; which is what I would always adviſe, as being of great Uſe to keep the Froſt out in very hard Winters. If theſe Piers are made of Stone, I would have them about twenty Inches broad in Front, and ſlop'd off backward to about ten Inches broad, whereby the Rays of the Sun will not be taken off or obſtructed by the Corners of the Piers, which it would be if they were ſquare: But if they are built with Bricks, it will be proper to make them two Feet in Front, otherwiſe they will be too weak to ſupport the Building; and theſe I would alſo adviſe to be ſlop'd off in the Manner directed for the Stone.



The Upright of the Greenhouſe and Stoves



A *The Ground plot of the Greenhouſe* B *The Ground plot of the Stoves* C *The Sheds behind the Stoves and Greenhouſe*

place this Cut at the Word Greenhouſe

At the Back of the *Green-houſe* there may be erected a Houſe for Tools, and many other Purpoſes, which will be extreme uſeful, and alſo prevent the Froſt from entering the Houſe that Way; ſo that the Wall between theſe need not be more than two Bricks in Thickneſs; whereas, if it were quite expos'd behind, it ſhould be two Bricks and an half, or three Bricks in thickneſs: And by this Contrivance, if you are willing to make a handſome Building, and to have a noble Room over the *Green-houſe*, you may make the Room to come over the Tool-houſe, and carry up the Stair-caſe in the Back, ſo as not to be ſeen in the *Green-houſe*; and hereby you may have a Room twenty or twenty-five Feet in Width, and of a proportionable Length: And under this Stair-caſe there ſhould be a private Door into the *Green-houſe*, at which the Gardener may enter in hard-froſty Weather, when it will not be ſafe to open any of the Glaſſes in the Front. The Floor of the *Green-houſe*, which ſhould be laid either with Marble, Stone, or Broad Tiles, according to the Fancy of the Owner, muſt be rais'd two Feet above the Level of the Ground whereon the Houſe is placed, which, in dry Ground, will be ſufficient: but if the Situation be moiſt and ſpringy, and thereby ſubject to Damps, it ſhould be rais'd at leaſt three Feet above the Surface: And under the Floor, about two Feet from the Front, I would adviſe a Flue of about ten Inches in width, and two Feet deep, to be carried the whole Length of the Houſe, which may be return'd along the Back-part, and be carry'd up in proper Funnels adjoining to the Tool-houſe, by which the Smoke may paſs off. The Fire-place may be contriv'd at one End of the Houſe; and the Door at which the Fuel is put in, as alſo the Aſh-grate may be contriv'd to open into the Tool-houſe, ſo that it may be quite hid from the Sight, and be in the dry; and the Fuel may be laid in the ſame Place, whereby it will be always ready for Uſe.

I ſuppoſe many People will be ſurprized to ſee me direct the making of Flues under a *Green-houſe*, which has been diſuſed ſo long, and by moſt People thought of ill Conſequence; as indeed they have often prov'd, when under the Direction of unſkilful Managers, who have thought it neceſſary, whenever the Weather was cold, to make Fires therein. But however injurious Flues have been under ſuch Miſmanagement, yet when ſkilfully managed, they are of very great Service: for though perhaps it may happen that there will be no Neceſſity to make any Fires in 'em for two or three Years together, as when the Winters prove mild there will not, yet in very hard Winters they will be extremely uſeful to keep out the Froſt; which cannot be effected any other way, but with great Trouble and Difficulty.

Within-ſide of the Windows, in Front of the *Green-houſe*, you ſhould have good ſtrong Shutters, which ſhould be made with Hinges, to fold back, ſo that they may fall back quite cloſe to the Piers, that the Rays of the Sun may not be obſtructed thereby: Theſe Shutters need not be above an Inch thick, or little more, which, if made to join cloſe, will be ſufficient to keep out our common Froſt; and when the Weather is ſo cold as to endanger the freezing in the Houſe, it is but making a Fire in your Flue, which will effectually prevent it: and without this Conveniency it will be very troubleſome, as I have often ſeen, where Perſons have been obliged to nail Mats before their Windows, or to ſtuff the hollow Space between the Shutters and the Glaſs with Straw; which, when done, is commonly ſuffer'd to remain 'till the Froſt goes away; which, if it ſhould continue very long, the keeping the *Green-houſe* ſo cloſely ſhut up, will prove very injurious to the Plants: And as it frequently happens that we have an Hour or two of the Sun-ſhine in the middle of the Day, in continued Froſts, which are of great Service to Plants, when they can enjoy the Rays thereof through the Glaſſes; ſo when there is nothing more to do than to open the Shutters, which may be perform'd in a very ſhort time, and as ſoon ſhut again when the Sun is clouded, the Plants may have the Benefit thereof whenever it appears: whereas where there is ſo much Trouble to uncover, and as much to cover again, it would take up the whole Time in uncovering and ſhutting them up, and thereby the Advantage of the Sun's Influence would be loſt. Beſides, where there is ſo much Trouble requir'd to keep out the Froſt, it will be a great Chance if it be not neglected by the Gardener; for if he be not as fond of preſerving his Plants, and as much in love with 'em as his Maſter, this Labour will be thought too great by him; and if he does take the Pains to cover the Glaſſes up with Mats, *&c.* he will not care to take them away again until the Weather alters; ſo that the Plants will be ſhut up cloſe during the whole Continuance of the Froſt.

There are ſome People who commonly make uſe of Pots fill'd with Charcoal to ſet in their *Green-houſe* in very ſevere Froſts, but this is very dangerous to the Perſons who attend theſe Fires; and I have often known they have been almoſt ſuffocated therewith; and at the ſame time they are very injurious to the Plants: Nor is the Trouble of tending upon theſe ſmall; and the many Hazards to which the Uſe of theſe Fires are liable, have juſtly brought them into Diſuſe with all ſkilful Perſons: And as the Contrivance of Flues, and the Charge of the Fires, are but ſmall, ſo they are much to be preferr'd to any other Method for warming the Air of the Houſe.

The Back-part of the Houſe ſhould be plaiſter'd with Mortar, and white-waſh'd; or, if lined with Wainſcot, ſhould be painted white, as ſhould the Ceiling, and every Part within-ſide of the Houſe; for this reflects the Rays of Light in a much greater Quantity than any other Colour, and is of ſignal Service to Plants, eſpecially in the Winter, when the Houſe is pretty much cloſ'd, ſo that but a ſmall Share of light is admitted through the Windows; and at ſuch time I have obſerved, that in ſome *Green-houſes* which have been painted black, or of a dark Colour, the Plants have caſt moſt of their Leaves.

In this *Green-houſe* you ſhould have Truſſels, which may be mov'd out and into the Houſe, upon which you ſhould place Rows of Planks, ſo as to fix the Pots or Tubs of Plants in regular Rows one above another, whereby the Heads of the Plants may be ſo ſituated as not to interfere with each other: The loweſt Row of Plants, which ſhould be the forwardeſt towards the Windows, ſhould be plac'd about four Feet therefrom, ſo that there may be a convenient Breadth left next the Glaſſes to walk in Front; and the Rows of Plants ſhould riſe gradually from the firſt, in ſuch a manner, that the Heads of the ſecond Row ſhould be intirely advanced above the firſt, the Stems only being hid thereby: And at the Back-ſide of the Houſe there ſhould alſo be allow'd a Space of at leaſt five Feet, for the Conveniency of watering the Plants, as alſo to admit of a Current of Air round them, that the Damps, occaſion'd by the Perſpiration of the Plants, may be the better diſſipated; which, by being pent in too cloſely, often occaſions a Mouldineſs upon the tender Shoots and Leaves; and when the Houſe is cloſe ſhut up, this ſtagnating, rancid Vapour is often very deſtructive to the Plants: For which Reaſon alſo you ſhould never croud them too cloſe to each other: Nor ſhould you ever place *Sedums*, *Euphorbiums*, *Torch-thiſtles*, and other tender ſucculent Plants, amongſt *Oranges*, *Myrtles*, and other Ever-green Trees; for, by an Experiment which I made *Anno* 1729, I found that a *Sedum* placed in a *Green-houſe* among ſuch Trees, almoſt daily increas'd its Weight, although there was no Water given to it the whole time: Which Increaſe of Weight was owing to the Moiſture imbib'd from the Air, which being replete with the rancid Vapours perſpir'd from the other Plants, occaſion'd the Leaves to grow pale, and in a ſhort time they decay'd, and dropp'd off: which I have often obſerv'd has been the Caſe with many other ſucculent Plants, when plac'd in thoſe Houſes which were fill'd with many Sorts of Ever-green Trees, that requir'd to be frequently water'd.

Therefore, to avoid the Inconvenience which attends the placing of Plants of very different Natures in the ſame Houſe, it will be very proper to have two Wings added to the main *Green-houſe*; which, if placed in the Manner expreſſed in the annexed Plan, will greatly add to the Beauty of the Building, and alſo collect a greater Share of Heat. In this Plan the *Green-houſe* is placed exactly fronting the South; and one of the Wings faces the South-Eaſt, and the other the South-Weſt: ſo that from the time of the Sun's firſt Appearance upon any Part of the Building, until it goes off at Night, it is conſtantly reflected from one Part to the other; and the cold Winds are alſo kept off from the Front of the main *Green-houſe* hereby: and in the Area of this Place you may contrive to place many of the moſt tender exotick Plants, which will bear to be expoſed in the Summer-ſeaſon: And in the Spring, before the Weather will permit you to ſet out the Plants, the Beds and Borders of this Area may be full of *Anemonies*, *Ranunculus's*, early *Tulips*, &c. which will be paſt flowering, and the Roots fit to take out of the Ground by the time you carry out the Plants; which will render this Place very agreeable during the Spring-ſeaſon that the Flowers are blown; and here you may walk and divert yourſelf in a fine Day, when, perhaps, the Air in moſt Parts of the Garden will be too cold for Perſons not much us'd thereto, to take Pleaſure in being out of the Houſe.

In the Center of this Area may be contriv'd a ſmall Baſon for Water, which will be very convenient for watering Plants, and very much add to the Beauty of the Place: Beſides, the Water being thus ſituated, will be ſoftened by the Heat which will be reflected from the Glaſſes upon it, whereby it will be render'd much better than raw cold Water for theſe tender Plants.

The two Wings of the Building ſhould be contriv'd ſo as to maintain Plants of different Degrees of Hardineſs; which muſt be effected by the Situation and Extent of the Fire-place, and the Manner of conducting the Flues; a particular Account of which will be exhibited under the Article of *Stove*. But I would here obſerve, that the Wing facing the South-Eaſt ſhould always be preferr'd for the warmeſt Stove; its Situation being ſuch, as that the Sun, upon its firſt Appearance in the Morning, ſhines directly upon the Glaſſes; which is of great Service in warming the Air of the Houſe, and adding Life to the Plants, after having been ſhut up during the long Nights in the Winter-ſeaſon. Theſe Wings being, in the Draught annex'd, allow'd ſixty Feet in Length, may be divided in the Middle by Partitions of Glaſs, with Glaſs-doors to paſs from one to the other; and the Fire-place may be order'd ſo as to warm both Diviſions, by placing a Regulator of Iron in the Flue, ſo that the Smoke may paſs thro' the Flues of which Part ſoever you pleaſe; and, by this Contrivance, you may keep ſuch Plants as require the ſame Degree of Heat in one Part of the Houſe, and thoſe which will thrive in a much leſs Warmth in the other Part: But this will be more fully explain'd under the Article of *Stoves*.

The other Wing of the Houſe, facing the South-Weſt, may alſo be divided in the ſame Manner, and Flues carried thro' both Parts, which may be us'd according to the Seaſons, or the particular Sorts of Plants which are plac'd therein: So that here will be four Diviſions in the Wings, each of which may be kept up to a different Degree of Warmth; which, together with the Green-houſe, will be ſufficient to maintain Plants from all the ſeveral Countries of the World: And without having theſe ſeveral Degrees of Warmth, it will be impoſſible to maintain Plants from all the ſeveral Countries of the World: And without having theſe ſeveral Degrees of Warmth, it will be impoſſible to preſerve the various Kinds of Plants from the ſeveral Parts of *Africa* and *America*, which are annually introduced into the *Engliſh* Gardens; for when Plants from very different Countries are placed in the ſame Houſe, ſome are deſtroy'd for want of Heat, while others are forc'd and ſpoil'd by too much of it; and this is often the Caſe in many Places, where there are large Collections of Plants.

But beſides the Conſervatories here mention'd, it will be proper to have a deep Hot-bed Frame, (ſuch as is commonly uſed to raiſe large Annuals in the Spring) into which may be ſet Pots of ſuch Plants as come from *Carolina*, *Virginia*, &c. while the Plants are too ſmall to plant in the open Air; as alſo many other Sorts from *Spain*, &c. which require only to be ſkreen'd from the Violence of Froſts; and ſhould have as much free Air as poſſible in mild Weather, which can be no better effected than in one of theſe Frames, where the Glaſſes may be taken off every Day when the Weather will permit, and put on every Night; and in hard Froſts the Glaſſes may be covered with Mats, Straw, Peaſe-haulm, or the like, ſo as to prevent the Froſt from entering the Pots to freeze the Roots of the Plants, which is what will, many Times, utterly deſtroy them; tho' a ſlight Froſt pinching the Leaves or Shoots very ſeldom does them much Harm: As to the Structure of theſe Frames, it will be fully explained under the Article of *Hotbeds*.

GROSSULARIA, [ſo called from the groſs or thick Skin of the Fruit; becauſe the Skin of this Shrub is carnoſe and fleſhy: It is alſo called *Uva*, becauſe the Fruit reſembles a *Grape*; and *Criſpa*, becauſe it is villoſe and hairy: It is ſaid to be *acino ſimplici*, becauſe its Berries are diſtinct one from another, and do not grow in Cluſters] The Gooſeberry Tree.

The *Characters* are;

The Leaves are laciniated, or jagged: The whole Plant is ſet with Prickles: The Fruit grows ſparſedly upon the Tree, having, for the moſt part, but one Fruit upon a Foot-ſtalk, which is of an oval or globular figure, containing many ſmall Seeds, ſurrounded by a pulpy Subſtance.

The *Species* are;

1. Grossularia *ſimplici acino, vel ſpinoſa ſylveſtris. C. B. P.* The common Gooſeberry.
2. Grossularia *ſpinoſa ſativa. C. B. P.* The large manured Gooſeberry.
3. Grossularia *fructu obſcure purpuraſcente. Cluſ.* The red hairy Gooſeberry.
4. Grossularia, *ſive Uva criſpa alba, maxima rotunda. Hort. Ed.* The large white *Dutch* Gooſeberry.
5. Grossularia *maxima ſubflava oblonga. Hort. Ed.* The large Amber Gooſeberry.
6. Grossularia *fructu rotundo maximo viraſcente.* The large green Gooſeberry.
7. Grossularia *fructu rubro majore. Boerh. Ind.* The large red Gooſeberry.
8. Grossularia *ſpinoſa ſativa, foliis flaveſcentibus.* The yellow-leaf'd Gooſeberry.
9. Grossularia *ſpinoſa ſativa, foliis ex luteo variegatis.* The ſtrip'd-leaf'd Gooſeberry.

There are ſeveral other Varieties of this Fruit which have been obtain'd from Seeds in different Parts of *England*, which differ either in the Shape or Colour of the Berries: But as theſe are only ſeminal Variations, ſo it is needleſs, in this Place, to enumerate them, eſpecially ſince the Number of theſe will be increas'd continually from Seeds.

Theſe are propagated either by Suckers taken from the old Plants, or by Cuttings; the latter of which I prefer to the former: becauſe thoſe Plants which are produced from Suckers are always more diſpoſed to ſhoot out a greater Number of Suckers from their Roots, than ſuch as are raiſed from Cuttings, which do generally form much better Roots.

The beſt Seaſon for planting theſe Cuttings is in *February*, juſt before their Buds begin to open; obſerving always to take the handſomeſt Shoots, and from ſuch Branches as generally produce the greateſt Quantity of Fruit; ſo if you take thoſe which are produced from the Stem of the old Plants, (which are commonly very luxuriant) they will not be near ſo fruitful as thoſe taken from bearing Branches: Theſe Cuttings ſhould be about ſix or eight Inches long, and muſt be planted in a Border of light Earth expoſed to the Morning Sun, about three Inches deep, obſerving to water them gently, when the Weather proves dry, to facilitate their taking Root; and in the Summer, when they have put out, you ſhould rub off all the under Shoots, leaving only the uppermoſt or ſtrongeſt, which ſhould be train'd upright to form a regular Stem. In *October* following theſe Plants will be fit to remove; at which Time you ſhould prepare an open Spot of freſh Earth, which ſhould be well dug, and cleans'd from all noxious Weeds, Roots, *&c.* and being levell'd, you ſhould proceed to take up your Plants, trimming their Roots, and cutting off all lateral Side-branches; then plant them at three Feet Diſtance Row from Row, and one Foot aſunder in the Rows, obſerving to place ſome ſhort Sticks to the Plants, in order to train their Stems upright and regular. In this Place they may remain two Years, being careful to keep them clear from Weeds, as alſo dig up the Ground between the Rows once a Year, which ſhould be in the Spring; as alſo to trim off all lateral Shoots which are produced below the Head of the Plant, ſo that the Stem may be clear about a Foot in Height above the Surface of the Earth, which will be full enough: And as the Branches are produced commonly very irregular in the Head, ſo you muſt cut out ſuch of them as croſs each other, or thin them where they are too cloſe, whereby the Head of the Plant will be open, and capable of admitting the Air freely into the Middle, which is of great Uſe to all Kinds of Fruits.

After theſe Plants have remain'd in this Nurſery two Years, they will be fit to tranſplant to the Places where they are deſign'd to remain; for it is not ſo well to let them grow in the Nurſeries too large, which will occaſion their Roots to be woody, whereby the removing of them will not only hazard the Growth of the Plants, but ſuch of them as may take very well, will remain ſtunted for two or three Years before they will be able to recover their Check. The Soil in which theſe Plants thrive to the greateſt Advantage, is a rich, light, ſandy Loam; tho' they will do very well upon moſt Soils and Situations: But where this Fruit is cultivated, in order to procure it in the greateſt Perfection, they ſhould never be planted in the Shade of other Trees, but muſt have a free open Expoſure: The Diſtance they ought to be planted is eight Feet Row from Row, and ſix Feet aſunder in the Rows: The beſt Seaſon for tranſplanting them is in *October*, when their Leaves begin to decay; obſerving, as was before directed, to prune their Roots, and trim off all lateral Shoots, or ſuch as croſs each other, ſhortning all long Branches, ſo as to make the Head regular.

In the pruning of theſe Shrubs, moſt People make uſe of Garden-ſheers, obſerving only to cut the Head round, as is practiſed for Ever-greens, *&c.* whereby the Branches become ſo much crouded, that what Fruit is produced, never grows to half the Size as it would do, were the Branches thin'd and prun'd according to Art; which ſhould always be done with a pruning Knife, ſhortning the ſtrong Shoots to about ten Inches, and cutting out all thoſe which grow irregular, and thinning the Fruit-bearing Branches where they are too thick; obſerving always to cut behind a Leaf-bud: With this Management your Fruit will be near twice as large as thoſe which are produced upon ſuch Buſhes as are not thus pruned, and the Shrubs will continue in Vigour much longer: But you muſt obſerve to keep the Ground clear from Weeds, and dig it at leaſt once a Year; and every other Year you ſhould beſtow a little rotten Dung upon it, which will greatly improve the Fruit.

It is a common Practice with the Gardeners near *London*, who have great Quantities of theſe Buſhes, in order to ſupply the Markets, to prune them ſoon after *Michaelmas*, and then to dig up the Ground between the Rows, and plant it with Coleworts for Spring Uſe, whereby their Ground is employed all the Winter without prejudicing the *Gooſeberries*; and in hard Winters theſe Coleworts often eſcape, when thoſe which are planted in an open Expoſure, are all deſtroy'd; and theſe are generally pull'd up for Uſe in *February* or *March*, ſo that the Ground is clear before the *Gooſeberries* come out in the Spring; which is a Piece of Huſbandry well worth practiſing where Ground is dear, or where Perſons are confined for Room.

GUAIABARA, Sea-ſide Grape, *vulgo*.

The *Characters* are;

It hath a Flower conſiſting of ſix Leaves, which expand in Form of a Roſe; in the Center ariſes the Pointal, which afterward becomes a pulpy Fruit, incloſing one roundiſh Stone terminating in a Point.

The *Species* are;

1. GUAIABARA *alia racemoſa, foliis oblongis. Plum. Manuſ.* Sea-ſide Grape with oblong Leaves.
2. GUAIABARA *alia racemoſa, foliis latiſſimis. Houſt.* Sea-ſide Grape with very broad Leaves.
3. GUAIABARA *foliis minoribus & longioribus, fructu racemoſo minimo atro-purpureo. Houſt.* Sea-ſide Grape with ſmaller and longer Leaves, and the leaſt dark purple Fruit growing in Bunches.

The ſecond Sort is very common in *Jamaica*, and all the *Caribee Iſlands*; where it grows on the ſandy Shores, from whence it had the Name of *Sea-ſide Grapes*, the Fruit growing in a long ſlender Bunch. This Fruit is commonly ſold in the Markets in *Barbadoes*, where it is much eſteemed.

The firſt Sort is common at *Carthagena* in *New Spain*, from whence I received the Seeds; which were collected by the late Dr. *William Houſtoun*.

The third Sort was alſo diſcovered by the ſame Gentleman at *la Vera Cruz*; who ſent the Seeds into *England*, from which ſeveral Plants were raiſed. Theſe two Sorts alſo grow on the ſandy Shores near the Sea.

Theſe Shrubs do uſually grow about ten or twelve Feet high, and have ſeveral Trunks ariſing from the ſame Root, ſo that they appear like large Buſhes. The Fruit comes out from the Wings of the Leaves in long ſlender Bunches, which are about the Size of an ordinary Raiſin in the ſecond Sort; but the firſt and third Sorts produce very ſmall Fruit, which are ſeldom gathered. The ſecond Sort is figured in *Lobel*'s *Hiſtory of Plants* under the Title of *Populus Novi Orbis*.

All theſe Sorts are propagated by Seeds, which ſhould be ſown in ſmall Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark: In about a Month after, the Plants will appear above Ground, when they muſt be frequently watered and cleared from Weeds: If the Weather proves warm, the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants; but if the Nights are cold, the Glaſſes muſt be covered with Mats every Night, to preſerve a gentle Warmth in the Bed. When the Plants are about two Inches high, they muſt be ſhaken out of the Pots, and ſeparated carefully, planting each into a ſmall Pot filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to ſcreen them from the Sun every Day, until they have taken Root; after which Time they ſhould have Air admitted to them every Day, in Proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed; they muſt alſo be frequently watered in hot Weather. When the Plants have filled the Pots with their Roots, they muſt be tranſplanted into larger Pots, and plunged again into the Hot-bed, where they may remain till *Michaelmas*; at which Time they ſhould be removed into the Stove, and plunged into the Tan. During the Winter Seaſon, they muſt be kept very warm, and frequently refreſhed with Water, but it muſt not be given to them in large Quantities; but in Summer, they ſhould have freſh Air admitted to them in warm Weather, and watered more plentifully, but they muſt conſtantly remain in the Stove; for they are too tender to live in the open Air in this Country in the warmeſt Seaſon. Theſe Plants having thick, ſtrong, green Leaves, make an agreeable Appearance in the Stoves; and it may be expected to ſee the Fruit brought to Perfection in ſome of the Stoves which have been lately erected.

GUAJACANA; *Indian* Date Plum, *or* Baſtard Lote-Tree.

The *Characters* are;

The Leaves are produced alternately upon the Branches, which fall off in Winter: The Cup of the Flower is divided into three Parts: The Flower conſiſts of one Leaf of a Bell-ſhape, the under Part being tubuloſe, and the upper Part is cut into five or more Segments, and is expanded: In the Center of the Cup ariſes the Ovary, which becomes a ſoft, roundiſh Fruit, having many depreſs'd Cells, in which are contained many hard Seeds diſpoſed in a circular Order.

The *Species* are;

1. GUAJACANA. *J. B.* The *Indian* Date Plum-Tree.
2. GUAJACANA *anguſtiore folio. Tourn.* Narrow-leaf'd *Indian* Date Plum-Tree.
3. GUAJACANA *Piſhamin Virginianum. Park. Theat. Boerh. Ind. Virginian* Date Plum, *or* Piſhamin.

The firſt and ſecond Sorts are at preſent very rare in *England*, and only to be found in ſome curious Gardens; but the third Sort is more common; they are all ſuppoſed to be Natives of the *Weſt Indies*: The laſt Sort hath been raiſed in great Plenty, of late Years, in the Gardens near *London*, from Seeds which have been brought from *Virginia* and *Carolina*, in both which Countries this Tree greatly abounds.

Theſe Plants may be propagated by ſowing the Seeds (which are often brought into *England*) upon a moderate Hot-bed, in the Spring of the Year; and when the Plants come up, they ſhould be tranſplanted each into a ſeparate Half-penny Pot, which ſhould be filled with freſh, light, ſandy Earth, and plunged into another moderate Hot-bed, to facilitate their taking Root; and as the Summer advances, ſo you ſhould inure them to the open Air by Degrees; and in *June* they may be removed into ſome Place that is pretty well ſhelter'd from Winds, where they may remain until *October*, at which Time they ſhould be removed under the Shelter of a Hot-bed Frame, or into the Green-houſe, during the firſt Winter: But in *April* following they may be ſhaken out of the Pots, and tranſplanted into the open Air, where they will thrive very faſt, and reſiſt the Cold of our Winters very well, provided they are planted in a dry Soil, and not too much expoſed to ſevere Winds.

They may alſo be propagated by laying down the young Shoots in the Spring, which, if kept ſupplied with Water in very dry Weather, will take Root by the ſucceeding Spring, when they may be tranſplanted where they are to remain: The beſt Seaſon for tranſplanting theſe Trees is at the latter End of *March*, juſt before they begin to ſhoot; at which Time, if Care be taken not to hurt their Roots, there will be little Danger of their not ſucceeding, if the Plants are young: But they are very difficult to remove when they are grown large; therefore if your Ground be not ready to tranſplant theſe Trees into while young, you ſhould keep them in Pots or Tubs until it be ſo, that they may be turned out with a Ball of Earth to their Roots, which will be much the ſureſt Method.

The *Piſhamin* is very ſubject to ſend forth great Number of Suckers from the Root, ſo that there will never want a Supply of Shoots for Laying; which is by far the beſt Method of managing them; tho' ſometimes they may be taken from the old Plants with Roots to them: Yet theſe Roots are ſeldom very good, and will always be ſubject to puſh out a greater Quantity of Suckers than ſuch as are produced by Layers; which is what no one would covet in any Sort of Trees, unleſs for the ſake of increaſing the Number; for they ſeldom make ſuch fair Trees as the other. This makes a very large, beautiful Tree in *Virginia*, and ſeems diſpoſed to grow to the ſame Stature with us. There was formerly a large Tree of this Kind in the Gardens of the Biſhop of *London* at *Fulham*, which flower'd; but this hath been cut down many Years, to make Room for Kitchen Stuff, ſo that at preſent there are very few: Some of them have flower'd and produced Fruits, but they have not ripen'd, our Autumns not proving ſo favourable as could be wiſhed.

GUAIACUM; Lignum Vitæ.

The *Characters* are;

It hath pinnated Leaves: The Flower conſiſts of ſeveral Petals, which are placed orbicularly, and expand in form of a Roſe: The Pointal of the Flower, which ariſes from the Center of the Calyx, becomes a fleſhy, roundiſh, ſtony Fruit, or the ſtony Seeds are ſurrounded with a thin Pulp.

The *Species* are;

1. GUAIACUM, *flore cæruleo, fructu ſubrotundo. Plum.*

Lignum Vitæ, or Wood of Life, with a blue Flower, and roundiſh Fruit.

2. Guaiacum, *flore cœruleo, fimbriato, fructu tetragono. Plum.* Lignum Vitæ, with a blue fringed Flower, and a four-corner'd Fruit.

Theſe two Plants are Natives of the hotteſt Parts of the *Weſt-Indies*, and are with great Difficulty tranſplanted into *England*; for their Seeds ſeldom riſe with us, unleſs they are brought very freſh, and are ſown ſoon after they arrive: I have ſome young Plants in the *Phyſick-Garden*, that were rais'd from Seeds, *Anno* 1726, which have come on very well, tho' they are naturally Plants of a very ſlow Growth.

Theſe Plants may be brought over from *America* in any of the Summer Months, which is the ſureſt Method to obtain them, their Seeds being very difficult to grow: but great Care ſhould be taken to tranſplant them into a Tub or Box of Earth at leaſt a Month before they are put on Board the Ship, that they may be ſettled in the Earth, and Charge given to the Sailors not to over-water them in their Paſſage; which is what hath deſtroy'd more Plants ſent from abroad, than either the Cold, or any other Accident or Management whatever.

When the Plants arrive, they ſhould be immediately taken out of the Tubs, preſerving ſome Earth about their Roots, and planted into Pots fill'd with good freſh rich Earth, and plung'd into a Hot-bed of Tanners-bark, to facilitate their making freſh Roots, that they may be enabled to live during the Winter; for if they are not well rooted in the Earth before the cold Weather comes on, it will be difficult to preſerve them.

In *October* they ſhould be removed into a warm Stove, where the Thermometer ſhould be kept up to twenty Degrees above Temperate, (as mark'd on Mr. *Fowler*'s Thermometers); and during the Winter-ſeaſon they ſhould be often refreſh'd with Water: but it ſhould be given them very cautiouſly; for too much Moiſture is very hurtful to theſe Plants. You ſhould alſo carefully waſh their Leaves, from time to time, to cleanſe them from Filth, which is very ſubject to lodge upon the Surfaces thereof: And in Summer they ſhould have a good Share of freſh Air, by opening the Glaſſes of the Stove: but they ſhould never be wholly expoſed to the open Air, even in the hotteſt Seaſon, unleſs for a ſhort time, in a gentle warm Shower of Rain, which will waſh the Leaves, and greatly refreſh them.

The Wood of theſe Trees is ſo hard as to break the Tools in felling them; ſo that it is ſeldom cut down for Firewood, being very difficult to burn.

GUAJAVA; The Guava.

The *Characters* are;

The Flowers, for the moſt part, conſiſt of five Leaves, which are produced in a circular Order, and expand in form of a Roſe, having many Stamina, *or Threads, ſurrounding the Ovary: The Ovary is of a long tubulous Figure, which becomes a fleſhy Fruit, crown'd on the Top, and containing many ſmall hard Seeds.*

The *Species* are;

1. Guajava *alba dulcis. H. L.* The white Guava.
2. Guajava *rubra, acida, fructu rotundiori. H. L.* The red Guava.

Theſe Trees grow to the Height of twenty Feet, or more, in the *Weſt-Indies*, and have Trunks as thick as a Man's Thigh: but with us in *England* they are preſerved in warm Stoves, and are rarely ſeen above ſix or ſeven Feet high; tho' there are ſeveral Trees which have produced Fruit in *England*.

Theſe Plants are propagated by ſowing their Seeds in a Hot-bed in the Spring; and when they are come up, they ſhould each of them be tranſplanted into a ſingle Half-penny Pot, filled with light rich Earth, and plunged into a freſh Hot-bed, in order to bring 'em forward; obſerving to give 'em Air, in proportion to the Warmth of the Weather, by raiſing the Glaſſes with Stones, *&c.* and in the great Heat of the Day you ſhould ſhade the Glaſſes with Mats, to prevent their being ſcorched: and in Summer-time they will require to be frequently watered. As they increaſe in Bulk, ſo you muſt ſhift them into larger Pots: but you muſt be careful not to put them into Pots that are too large; for that will very much retard their Growth, as indeed it doth moſt other Plants; and towards the Beginning of *July* you muſt let them have a plentiful Share of Air, in order to harden them before Winter; for if you continue forcing them quite thro' the Summer, you will get them to be very large in one Seaſon: but then they'll be ſo tender, that 'twill be difficult to preſerve them in Winter.

At the Latter-end of *Auguſt*, or Beginning of *September*, you ſhould remove the Pots into the Stove, where they ſhould be placed in a moderate Situation, *i. e.* not too near the Fire, nor at too great a Diſtance therefrom; the Temperate Heat, as mark'd on Mr. *Fowler*'s Thermometers, agreeing better with them than a Great Degree. During the Winter-ſeaſon they muſt be often refreſhed with Water, eſpecially if they are placed upon Shelves in the Stove: but if they are plunged into Tanners-bark, they will not require it ſo often; nor muſt they have too much given at a time; and the Water wherewith they are water'd ſhould be placed in the Stove at leaſt twenty-four Hours before it be uſed, that it may be nearly of an equal Proportion of Warmth with the Air of the Houſe. You ſhould alſo frequently waſh their Leaves with a Cloth in Winter, in order to cleanſe them from Duſt and other Filth which may have been collected upon the Surfaces of the Leaves during their being in the Houſe; as alſo from Vermin, which are very ſubject to infeſt theſe Plants. In the Summer you may expoſe them to the Air, by removing or opening the Glaſſes in the Front of the Stove: but they ſhould never be ſuffered to ſtand abroad, unleſs it be for a few Hours, in a warm Rain, to waſh them; for when they are treated too hardily, they will never produce either Fruit or Flowers; whereas, when they are rightly managed, they will flower the third Seaſon after their being ſown.

Theſe Trees are planted every-where in the *Caribbee* Iſlands for their Uſefulneſs; tho' the uſual Manner of their Cultivation is by being eaten: The Seeds paſſing intire thro' the Body, are voided in the Excrements; ſo that where-ever the *Negroes* dung, there will never want a Supply of theſe Trees, which is often ſo great, as to become troubleſome to their Plantations and Savanna's.

“ The Fruit (ſays Sir *Hans Sloane*) is accounted extreme-
“ ly pleaſant, delicious, and wholſome, and may very deſer-
“ vedly take the firſt Place among the *Weſt-Indian* Fruits, if
“ eaten when thoroughly ripe. They have (continues he)
“ only this Inconvenience, that being very aſtringent, they
“ ſtop up the Belly, if eaten in great Quantities; and the
“ Seeds ſometimes ſticking to the hard Excrement, in coming
“ through the Inteſtines, eſpecially the *Rectum*, by their irre-
“ gular ſharp Angles, will occaſion very great Pain there, and
“ very often bring a Flux of Blood.”

GUANABANUS.

This is the *American* Name by which theſe Fruits are called, and by Father *Plumier* is made the generical Name; but as many of theſe Sorts are enumerated under the Title *Anona*; ſo I ſhall only take Leave to add a few Sorts, which have been lately introduced into the *Engliſh* Gardens.

1. Guanabanus *folio ampliſſimo, flore roſeo, fructu purpureo ſquamato.* Cherimonias with a roſe-coloured Flower, and a purple ſcaly Fruit.
2. Guanabanus, *latifolia, flore albo, fructu aureo ſquamato.* Cherimonias with a broad Leaf, a white Flower, and a golden ſcaley Fruit.
3. Guanabanus *perſeæ folio, flore intus albo, exterius vireſcente, fructu nigricante ſquamato, vulgo Cherimolia. Feuill. Obſ.* Guanabanus with an avocado-pear Leaf, and Flowers which are white within, and greeniſh on the Outſide, and a ſcaly blackiſh Fruit, commonly called *Cherimolia* or *Cherimonias*, in the *Spaniſh Weſt-Indies.*

Theſe three Sorts grow in ſeveral Parts of the *Spaniſh Weſt-Indies*, where they are cultivated for their Fruits, which are greatly eſteemed by the Inhabitants.

They are very tender Plants, ſo muſt be preſerved in the warmeſt Bark-ſtove, otherwiſe they will not live in this Country. They are propagated by Seeds, which ſhould be ſown in Pots filled with rich light Earth, and plunged into a Hot-bed of Tanners Bark; when the Plants are come up two Inches high, they ſhould be tranſplanted into ſeparate ſmall Pots filled with light rich Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root; after which Time they muſt be treated, as hath been directed for the *Anona's*.

The third Sort is much cultivated in the Gardens in *Peru*, and ſeveral other Places in the *Spaniſh Weſt-Indies*, where the Fruit is greatly eſteemed, being by many Perſons preferred to the Pine-apple. This Tree ſeldom grows above twelve or fourteen Feet high in the *Weſt-Indies* : ſo that we may hope to ſee the Fruit in Perfection in this Country in a few Years ; becauſe, as the Tree is of humble Growth, it may be contained in the warmeſt Stoves.

The Seeds of this Kind were brought into *England* in the Year 1734, from the *Spaniſh Weſt-Indies*, by a very curious Gentleman ; from which many Plants have been raiſed, which have flouriſhed greatly, where proper Care was taken ; ſo that there are many Plants already [*Mar.* 1738.] eight or nine Feet high, which may be expected to produce Fruit in a Year or two at fartheſt. This is propagated by Seeds, which muſt be ſown and managed as is directed for the former Sorts, and muſt be conſtantly preſerved in the Bark-ſtove.

GUAZUMA, Baſtard Cedar Tree, *vulgò*.

The *Characters* are ;

It hath a regular Flower conſiſting of five Leaves, which are hollowed like a Spoon at their Baſe, but at their Tops are divided into two Parts, like a Fork. The Flower-cup conſiſts of three Leaves, from whence ariſes the Pointal, which afterward becomes a roundiſh warted Fruit, which has five Cells incloſing many Seeds.

The *Species* are ;

1. GUAZUMA *arbor ulmi-folia, fructu ex purpura nigro. Plum. Nov. Gen.* The Baſtard Cedar Tree, *vulgò*.
2. GUAZUMA *frutex chamædryfolia, fructu lanuginoſo, major. Plum. Nov. Gen.* Shrubby *Guazuma* with a groundpine Leaf, and a larger woolly Fruit.
3. GUAZUMA *frutex, Chamædryfolia, fructu lanuginoſo, minor. Plum. Nov. Gen.* Shrubby *Guazuma* with a groundpine Leaf and a leſſer woolly Fruit.

The firſt Sort grows plentifully in the low Lands in *Jamaica*, where it riſes to the Height of forty or fifty Feet, and has a large Trunk. The Timber of this Tree is cut into Staves, for Caſks of all ſorts, and uſed for many other Purpoſes. The Fruit is eat by Cattle as it falls from the Trees, and is eſteemed very good to fatten them : ſo that the Planters often leave theſe Trees ſtanding in their Savannas, when they clear them from all other Wood ; becauſe, when there is a Scarcity of Graſs and other Food, theſe Fruit are a great Support to their large Cattle.

The other two Sorts are pretty common in ſeveral Parts of the *Weſt-Indies*, where they grow about ten or twelve Feet high ; but are of little Uſe to the Inhabitants.

Theſe Plants may be propagated by Seed, which ſhould be ſown early in the Spring, in ſmall Pots filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark : theſe Pots of Earth muſt be frequently watered to promote the Vegetation of the Seed ; and if the Nights prove cold, the Glaſſes of the Hot-bed muſt be covered with Mats, to preſerve a moderate Warmth in the Bed ; but in the Day-time, when the Sun ſhines warm, the Glaſſes ſhould be raiſed, to let the Steam which ariſes from the Bed, paſs off. When the Plants appear above Ground, they muſt be carefully cleared from Weeds, and often refreſhed with Water ; and the Glaſſes muſt be raiſed to admit freſh Air to them, otherwiſe they will draw up too weak : and when they are about two Inches high, they muſt be ſhaken out of the Pots, and parted carefully, planting each into a ſeparate ſmall Pot filled with light freſh Earth, and then plunged into the Hot-bed again, being careful to ſcreen them from the Heat of the Sun, until they have taken new Root ; after which Time they muſt have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed ; they muſt alſo be frequently refreſhed with Water in hot Weather, which will greatly promote their Growth. In this Bed the Plants may remain all the Summer, being careful to keep them clear from the Weeds ; and when the Plants have filled the ſmall Pots with their Roots, they ſhould be ſhaken out, and their Roots trimmed, and then put into Pots a Size larger. About *Michaelmas* the Plants muſt be removed into the Stove, and plunged into the Tan in a warm part of the Stove. During the Winter Seaſon they will not require ſo much Water as in Summer ; but they muſt be frequently refreſhed with a little Water, eſpecially if the Stove is kept warm. If their Leaves ſhould contract filth, it muſt be carefully waſhed off with a Spunge ; for if it is ſuffered to remain on them, it will greatly injure the Plants. Theſe Plants being very tender, they muſt conſtantly remain in the Stoves, giving them a good Share of freſh Air in Summer ; but in Winter they muſt be kept very warm, otherwiſe they will not live in this Country ; but if they are carefully managed, they will thrive very well, and afford an agreeable Variety in the Stove, amongſt other tender exotic Plants of the ſame Countries.

GUIDONIA.

The *Characters* are ;

The Cup of the Flower conſiſts of five Leaves, which are ſtiff, and of a thick ſucculent make, expanding in form of a Star ; theſe are of an Aſh-colour on the Out-ſide, and of a fine Purple on the Inſide : In the Centre of the Cup ariſes the Flower, which conſiſts of ſeveral Leaves, and expands in form of a Star : From the Bottom of the Flower ariſes the Pointal, which becomes a roundiſh Fruit, divided into three or four Cells, in which are contained many oblong Seeds.

The *Species* are ;

1. GUIDONIA *ulmi foliis, flore roſeo. Plum. Guidonia* with Elm Leaves, and a Roſe-colour'd Flower.
2. GUIDONIA *ulmi foliis, flore niveo. Plum. Nov. Gen.* Guidonia with Elm Leaves, and a white Flower.
3. GUIDONIA *aurantii foliis, aculeata. Plum. Nov. Gen.* Prickly Guidonia, with Orange Leaves.
4. GUIDONIA *nucis juglandis foliis, major. Plum. Nov. Gen.* Greater Guidonia, with Walnut-tree Leaves.
5. GUIDONIA *nucis juglandis foliis, minor. Plum. Nov. Gen.* Leſſer Guidonia, with Walnut-tree Leaves.

The *Characters* the firſt Sort do not very well agree with thoſe which *Pere Plumier* hath given to this Genus of Plants. However, as the modern Botaniſts have agreed, that this Plant here named is the ſame which is figured by *Commelin*, in the *Hortus Amſtelodamenſis*, with the Title of *Arbuſcula Ulmi facie Æthiopica, ramulis alatis, floribus purpuraſcentibus* ; ſo I have continued *Plumier*'s Name to it : Tho' I am in doubt whether our Plant is really the ſame with *Plumier*'s ; but it is undoubtedly that which *Commelin* has figured and deſcribed.

This Plant may be propagated by laying down the Branches in the Spring, which, by the ſucceeding *Spring*, will be rooted ſufficiently to tranſplant ; and they ſhould be taken up at the latter End of *March*, before the Plant ſhoots, and put into Pots fill'd with good rich Earth ; and if you ſet the Pots upon a moderate Hot-bed to forward their rooting, it will be a ſure Method : Tho' they ſhould not be too much forced ; nor ſhould they continue longer than to the End of *April* under Shelter, when they may be ſet abroad in ſome Place which is pretty well defended from ſtrong Winds, where they may remain until *October*, at which time they ſhould be remov'd into the Green-houſe, with *Oranges*, *Myrtles*, *Oleanders*, &c. placing them in the cooleſt Part of the Houſe ; for they are pretty hardy, requiring nothing more than to be protected from ſevere Froſt : And during the Winter-ſeaſon they ſhould have but little Water ; for they caſt their Leaves in Autumn ; and ſo being deſtitute of them until *April*, they are incapable of diſcharging much Moiſture : but in Summer they will require frequently to be water'd, without which they ſeldom produce Flowers.

Theſe may, with Care, be train'd up to the Height of eight or ten Feet, with regular Stems ; and their Heads may alſo be reduced into a handſome Shape : but they ſhould not be clip'd with Shears, for that will cauſe 'em to appear unſightly, as alſo prevent their flowering ; but rather ſhorten all ſtrong irregular Shoots with your Knife, obſerving to cut behind a Leaf-bud, otherwiſe the Stump left beyond the Eye will appear to Sight. The beſt Seaſon for this Operation is at the latter End of *March*, at which time you ſhould cut out all decay'd Branches, and ſhift the Plants into freſh Earth.

They may alſo be propagated by planting ſome ſtrong Cuttings into Pots of freſh Earth in *March*, and plunge them into a moderate Hot-bed, obſerving to water them, and ſhade the Glaſſes in the Heat of the Day, as alſo to give them a good Quantity of Air when the Weather is warm ; and in about a Month or ſix Weeks time they will have taken Root, when you muſt harden them by Degrees to the open Air, to which they muſt be expos'd in Summer, and manag'd as was directed for the Layers.

The other four Sorts are tenderer than the firſt, ſo muſt be placed in the Bark-ſtove, eſpecially while they are young, which will greatly forward their Growth : they may be all propagated by Seeds, which ſhould be ſown in Pots filled with light freſh Earth early in the Spring, and plunged into a Hot-bed of Tanners-bark. When the Plants come up, they muſt be duly watered, and clear'd from Weeds, in the Day-time. When the Weather is warm, the Glaſſes of the Hot-bed muſt be tilted with Stones, to admit freſh Air to the Plants ; but if the Nights prove cold, the Glaſſes muſt be covered with Mats, to keep the Bed warm. When the Plants are about three Inches high, they ſhould be carefully taken up, and each tranſplanted into a ſeparate Pot, and plunged into the

Hot-bed again, obſerving to ſhade them from the Sun until they have taken Root; after which Time they muſt be treated as hath been directed for the *Guazuma*. The two firſt Winters, theſe Plants may be placed in the Bark-ſtove; but when they have acquired Strength, they may be inured to bear the open Air in the warmeſt Part of the Summer; and in Winter they may be placed on Stands in the dry Stove, where, if they are kept in a moderate Temperature of Warmth, they will thrive very well, and produce their Flowers every Year in *July* and *Auguſt*; but they rarely perfect Seeds in this Country.

They may be alſo propagated by laying their Branches down into the Earth: this ſhould be done in *April*; and if they are duly watered, they will be rooted enough to tranſplant by the following Year; when they ſhould be taken off and tranſplanted into Pots, and managed as is directed for the ſeedling Plants. But when it is propoſed to increaſe theſe Plants after this Manner, it will be proper to encourage ſome Shoots near the Bottom of the Stems of the old Plants (from whence they are very apt to ſend forth Shoots); becauſe theſe will be much more convenient to make Layers, than thoſe which are placed higher from the Earth.

Some of theſe Plants will grow from Cuttings, when they are rightly managed. Theſe Cuttings ſhould be planted in the Beginning of *April* (juſt before the Plants begin to ſhoot) in Pots filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root, which will be in about two Months, if they ſucceed; when they may be inured to bear the open Air by degrees, and in *Auguſt* they may be tranſplanted into ſeparate Pots, and afterward muſt be managed as is before directed for the ſeedling Plants and Layers. The Plants thus raiſed, will produce Flowers much ſooner than thoſe raiſed from Seed; but they ſeldom grow to make ſo large Plants as thoſe do.

GUNDELIA.

This Plant was ſo named by Dr. TOURNEFORT, in Honour to Dr. GUNDELSCHEIMER, who found it in his Travels in Company with Dr. TOURNEFORT, in the *Levant*.

The *Characters* are;

It is a Plant with a ſloſculous Flower, gathered into a kind of Head, conſiſting of many Florets, coming out of a common Empalement, and ſitting on the Embryos of the Seed, which are hid in the Cells of the Empalement, and afterward become roundiſh Seeds ending in a Point.

The *Varieties* of this Plant are;

1. GUNDELIA *orientalis, acanthi aculeati foliis, floribus intenſe purpureis, capite aranæoſa lanugine obſito. Tourn. Cor.* Eaſtern Gundelia, with a prickly Bears-breech Leaf, deep purple Flowers, and an Head woven, as it were, with a Cobweb.
2. GUNDELIA *orientalis, acanthi aculeati folio, capite glabro. Tourn. Cor.* Eaſtern Gundelia, with a prickly Bears-breech Leaf, and a ſmooth Head.

The ſecond Sort is figured and deſcribed in the ſecond Volume of Dr. *Tournefort*'s Travels in the *Levant*. It was diſcovered, as I ſaid, by Dr. *Gundelſcheimer* near *Baibout*, in their Journey to *Armenia*, growing in dry ſtony Places.

The firſt ſort ſeems to be a Variety of the ſecond, and was found intermixed with it in the ſame Places.

Theſe Plants are propagated by Seed, which ſhould be ſown the Beginning of *March*, in a warm dry Border of freſh but lean Earth; for they will not live long in a moiſt rich Soil. When the Plants come up, they muſt be carefully cleared from Weeds; as they grow large, ſo they ſhould be thinned and tranſplanted out in warm Borders, leaving the Plants which are deſigned to remain about two Feet aſunder, that they may have Room to ſpread. After this there is no other Culture required, but to keep them clear from Weeds; and in two Years they will produce their Flowers, when they will make a fine Appearance amongſt other hardy Flowers in the Pleaſure-garden; but theſe Plants rarely perfect Seeds in this Country, which is the Caſe of ſeveral other of the headed Plants; for if the Seaſon ſhould prove moiſt at the Time when the Plants are in Flower, the Wet ſoaks into the Empalement where the Embryos of the Seed are lodged, which prevents their ripening, ſo that the Seeds muſt be procured from Abroad.

H A

HÆMANTHUS, [Ἁιμάνθος, of Ἅιμα *Blood*, and Ἄνθος, *Flower*], *i. e.* Blood-flower.

The *Characters* are;

It has two Leaves ſpringing from the Bulb on each Side, and bowing backwards: The Stem is ſingle, fungous, thick, and ſpeckled, bearing a ſingle Flower on the Top, as it is thought: The Flower appears naked, hexapetalous, (i. e. *conſiſting of ſix Petals*) *or heptapetalous,* (i. e. *conſiſting of ſeven Petals*): *but, upon a cloſe Examination, the Flower appears to be floſculous, having a Calyx conſiſting of ſix Leaves, after the manner of a* Tulip, *of a red Colour, among (or within) which are monopetalous Flowers that are hexapetaloides, conſiſting of ſix long, fine, deeply-cut Segments, tubulous at the Bottom, having ſix* Stamina, *proceeding from a triangular Ovary; and tricapſular,* i. e. *conſiſting of three* Capſulæ *or Partitions, in which are contain'd oblong Seeds to the Number of thirty in one Calyx: The Bulb is ſquamoſe, and often, as it were, bifoliated.*

The *Species* are;

1. HÆMANTHUS *Africanus. H. L.* Blood-flower, or African Tulip.
2. HÆMANTHUS *colchici foliis, perianthio herbaceo. Hort. Elth.* Blood-flower with meadow-ſaffron Leaves, and an herbaceous Empalement.

The firſt Sort was originally brought from the *Cape of Good-hope*, and hath been many Years preſerv'd in the curious Gardens in *Holland*, where they now have more Sorts than one; but in *England* it is ſtill very rare, and in but few Gardens. The Seaſon for tranſplanting the Bulbs is in *May* or *June*, when the Leaves are decayed, at which time they may be kept out of the Earth two or three Months without Damage; though the ſooner they are tranſplanted, the ſtronger the Roots will be, and more likely to flower. The Soil in which they muſt be planted ſhould be one half freſh Earth from a Paſture, and a fourth Part rotten Dung, and the other Part Sea Sand; theſe ſhould be well mixed two or three Months before uſed, that their Parts may be better incorporated: Then you ſhould put a few Stones in the Bottom of each Pot, that the Water may be the eaſier drain'd off; and afterwards put the Earth into the Pots, planting the Bulbs therein, only ſo deep as that their upper Parts may be juſt covered: Then place the Pots in a ſhady Situation, giving them now and then a little Water in very dry Weather; but you muſt obſerve, never to let them have too much Moiſture, eſpecially at the time when they are deſtitute of Leaves: In this Situation they may continue until the Beginning of *Auguſt*, when they muſt be removed to a warmer Place; for about that Seaſon they will begin to puſh out new Roots: but they may remain abroad until the Middle or latter End of *September*, at which time they ſhould be removed into a moderate Stove, where they muſt be carefully preſerved, obſerving frequently to refreſh them with Water; for now their Leaves will appear, and will in a ſhort time grow to a large Size, if the Roots are ſtrong: but you muſt not give them too much Water at once, which will endanger their rotting. The Stove in which theſe Plants are placed ſhould be kept to near the Temperate Heat as is marked on Mr. *Fowler*'s *Thermometers*, in which they will thrive very well, and, if the Bulbs are ſtrong, will produce their beautiful Flowers in Winter, which renders them very valuable, it being a time when few other Plants appear. Theſe Roots ſhould not be tranſplanted oftener than every other Year: but the Earth in the upper Part of the Pots ſhould be taken out twice a Year, and ſome freſh Earth put in, which will greatly ſtrengthen the Roots.

The ſecond Sort is a Native of *Africa*, from whence it was brought to the curious Garden of Mr. *Beaumont* in *Holland*, where it was propagated, and has been ſince diſtributed to many curious Perſons in ſeveral Parts of *Europe*. It is propagated by Off-ſets, which ſhould be taken off in *May*, at which Time theſe Plants begin to loſe their Leaves; for they are ready to put out new Leaves in *July*, and continue growing all the Autumn and Winter; but toward the End of *May* the Leaves begin to decay; at which Time the Plants ſhould be new potted, and if they have any Off-ſets which are ſufficiently rooted, they muſt be taken off, and planted in Pots filled with light rich Earth. In tranſplanting of theſe Plants, there muſt be particular Care to lay ſome Stones and Rubbiſh in the Bottom of the Pots to let the Moiſture paſs off; for if the Wet is detained in the Pots, it will ſoon cauſe the Roots to periſh.

During the Seaſon of their Inactivity, which is commonly from the Beginning of *May* to the Beginning of *July*, they muſt not have too much Water, leſt it rot their Roots; but when they are in Vigour, they will require a little more Wet.

Theſe Plants muſt be conſtantly kept in the dry Stoves; for they do not thrive well, if they are ſet Abroad, even in the warmeſt Part of the Summer; ſo that it is much the better Method to let them remain in the Stove, with *Euphorbiums*, and other tender ſucculent Plants, which require a large Share of free Air in warm Weather; in which Situation they will thrive exceeding well, and will annually produce their beautiful Flowers, which make a fine Appearance among other rare Plants. During the Winter-ſeaſon they muſt be kept in a moderate Temperature of Heat, and ſhould be frequently refreſhed with Water; but it muſt not be given to them in large Quantities, leſt it rot them. This Plant is not conſtant in the Time of its flowering, but the moſt uſual Seaſon is in *July* or *Auguſt*; but when it flowers in the Spring, it will ſometimes perfect Seeds in this Country; which, if ſown ſoon after they are ripe, and preſerved in the Stove till Spring, and then placed in a Hot-bed of Tanners-bark, will grow very well; and by this Method a much greater Increaſe of the Plants may be obtained in a Year or two, than could be by Off-ſets in many Years.

HALICACABUM. *Vide* Alkekengi.

HALICACABUS PEREGRINA. *Vide* Corindum.

HALIMUS. *Vide* Atriplex.

HARMALA; Wild Syrian Rue.

The *Characters* are;

The Leaves are produced alternately on the Branches: The Flower conſiſts of five Leaves, which expand in form of a Roſe: *The Ovary ariſes from the Bottom of the Calyx, and becomes a roundiſh Fruit, divided into three Cells.*

There is but one *Species* of this Plant at preſent known, which is,

HARMALA. *Dod.* Harmel, *or* Wild Rue.

This Plant is propagated by ſowing the Seeds in the Spring, either upon a moderate Hot-bed, or on a Border of light Earth; and when the Plants come up, they ſhould be tranſplanted into a Border of good light Earth, at the Diſtance of ſix Inches from each other, where they may remain until the ſucceeding Spring, when they may be removed to the Places where they are to continue. The ſecond Summer after ſowing they generally produce Flowers, and, if the Autumn proves favourable, will perfect their Seeds.

This Plant is mention'd in the Catalogue of *Simples* annexed to the *College Diſpenſatory*, as a Medicinal Plant; but it is rarely uſed in *England*: Nor is it a Plant of any great Beauty; ſo that it is rarely preſerved in Gardens, but for the ſake of Variety.

HAWTHORN. *Vide* Meſpilus.

HAZEL. *Vide* Corylus.

HEDERA; The Ivy-Tree.

The *Characters* are;

It is a paraſitick Plant, ſending forth Roots or Fibres from its Branches, by which it is faſtened to either Trees, Walls, or Pales which are near it, and from thence receives a great Share of its Nouriſhment: The Leaves are angular: The Flowers (for the moſt part) conſiſt of ſix Leaves, and are ſucceeded by round black Berries, which grow in round Bunches, each of which, for the moſt part, contains four Seeds.

The *Species* are;

1. HEDERA *arborea. C. B.* Common Ivy.
2. HEDERA *arborea, foliis cymis flaveſcentibus.* Common Ivy, with the Leaves upon the upper Part of the Shoots of a pale-yellow Colour.
3. HEDERA, *communis minor, foliis ex albo, & viridi variis. Boerh. Ind. alt.* The Silver-ſtriped Ivy.
4. HEDERA *communis minor, foliis ex luteo variegatis.* The yellow variegated Ivy.

The firſt of theſe Plants is very common in moſt Parts of *England*, growing ſometimes very large, and forming a Sort of Tree, and at other Times faſtening itſelf to whatever Tree, Wall, or Pale it ſtands near, where it appears like a trailing Plant, which has occaſioned moſt Botanick Writers to mention them as two diſtinct Plants, whereas in reality they are the ſame, their Difference being occaſioned by their different Situations; as may be often obſerved, when the upper Branches of theſe trailing Plants get above the Trees or Walls to which they are faſtened, then they grow more woody, and form large Heads producing Fruit; whereas that Part which is below never makes any Effort to produce either Flowers or Fruit.

Theſe Plants are eaſily propagated by their trailing Branches, which ſend forth Roots at every Joint; which Branches being cut off, and planted, will grow in almoſt any Soil or Situation, and may be trained up to Stems or ſuffered to remain Climbers, to cover Walls, Pales, &c.

They may alſo be propagated by Seeds, which ſhould be ſown ſoon after they are ripe: But they very often remain two Years in the Ground before they appear; which being a tedious Method, moſt People make uſe of the former, which is very expeditious and certain.

The ſecond Sort is a Variety of the firſt, from which it differs in having the Leaves upon the upper Part of the Branches, of a pale-yellow Colour: This is propagated in the ſame manner as the former, and may be preſerved for the ſake of Variety.

The third and fourth Sorts are very beautiful Plants, and are often planted againſt Walls or Buildings, where they adhere to the Brick, and grow ſo cloſe as to hide them from the Sight: Theſe alſo may be train'd up to regular Stems and Heads, and are increaſed as the former Sorts.

HEDERA TERRESTRIS. *Vide* Chamæciſſus.

HEDGES. Tho' Hedges are moſt commonly made of *Quick*, yet it will be proper, before planting, to conſider the Nature of the Land, and what Sort of Plants will thrive beſt in that Soil, whether it be Clay, Gravel, Sand, &c. and likewiſe what the Soil is from whence the Plants are to be taken; for if the Land they are taken from is better than that in which they are to be planted, it will be more difficult to get them to grow. As for the Size, the Sets ought to be about the Bigneſs of one's Thumb, and cut within about four or five Inches of the Ground; they ought to be freſh gathered, ſtrait, ſmooth, and well-rooted.

2dly: If the *Hedge* has a Ditch, it ſhould be made three Feet wide at Top, and one at Bottom, and two Feet deep, that each may have a Slope: But if the Ditch be four Feet wide, it ought to be two Feet and an half deep; and if it be five Feet wide, it ſhould be three Feet; and ſo in Proportion.

3dly: If the Bank be without a Ditch, the Sets ſhould be ſet in two Rows, almoſt perpendicular, at the Diſtance of a Foot from each other.

4thly: The Turf is to be laid with the Graſs-ſide downwards, on that Side of the Ditch the Bank is deſigned to be made; and ſome of the beſt Mould ſhould be laid upon it, to bed the Quick: Then the Quick is to be laid upon it, a Foot aſunder, ſo that the End of it may be inclining upwards; and at equal Diſtances of thirty Feet plant a young *Oak*, *Aſh*, *Crab*, or *Elm*, to grow with the *Quick*.

5thly: When the firſt Row of *Quick* is laid, it muſt be covered with Mould, and the Turf laid upon it, as before, and ſome Mould upon that; ſo that when the Bank is a Foot high, you may lay another Row of Sets againſt the Spaces of the lower *Quick*, and cover them as the former was done; and the Bank is to be topp'd with the Bottom of the Ditch, and a dry or dead *Hedge* laid to ſhade and defend the under Plantation.

6thly: Then there ſhould be Stakes driven into the looſe Earth, at about two Feet and an half Diſtance, ſo low as to reach the firm Ground.

Oak Stakes are accounted the beſt, and *Black-thorn* and *Sallow* the next: Let the ſmall Buſhes be laid below, but not too thick, only a little to cover the *Quick* from being bit by Cattle, when it ſprings; and alſo lay long Buſhes at the Top to bind the Stakes in with, by interweaving them.

And in order to render the *Hedge* yet ſtronger, you may *edder* it, (as it is call'd); *i. e.* bind the Top of the Stakes in with ſome ſmall long Poles or Sticks on each Side; and when the Eddering is finiſhed, drive the Stakes anew; becauſe the waving of the *Hedge*, and Eddering, are apt to looſen the Stakes.

The *Quick* muſt be kept conſtantly weeded, and ſecur'd from being cropp'd by Cattle; and in *February* it will be proper to cut it within an Inch of the Ground; which will cauſe it to ſtrike Root afreſh, and help it much in the Growth.

When an *Hedge* is of about eight or nine Years Growth, it will be proper to plaſh it: The beſt Time for this Work is either in *February*, or *October*.

When an *Hedge* is grown old, *i. e.* of about twenty or thirty Years Growth, and there are in it old Stubs, as well as new Shoots, the old Stubs ſhould be cut ſloping off within two or three Inches of the Ground; and the beſt and longeſt of the middle Size ſhould be left to lay down; and ſome of the ſtrongeſt, at the Height of five or ſix Feet, according as you deſign the Height of the *Hedge* to be, may be left to ſerve inſtead of Stakes; and freſh Stakes ſhould be put in thoſe Places where they are wanting: The *Hedge* ſhould be thinn'd, ſo as to leave on the Stubs only ſuch Shoots as are deſigned to be of Uſe, that there may be Room left to put a Spade in between them: The Ditch alſo ſhould be cleanſed, and each Side of the Slope kept as in a new Ditch: And where the Earth is waſh'd from the Roots of the Quick, or is hollow, face it anew with ſo much of the firſt Spit of Earth that is dug out of the Ditch, as there is Occaſion for; and lay what is dug out at the ſecond Spit, on the Top of the Bank; for if it be laid on the Side or Face of the Bank, it will ſlip into the Ditch again when Wet comes, and alſo take a great deal of the Bank along with it.

In planting *Quicks*, there are two Extremes to be avoided: The Firſt is, Laying it too low, and too thick; becauſe it makes the Sap run all into the Shoots, and leaves the Plaſhes without Nouriſhment; which, with the Thickneſs of the *Hedge*, kills them.

Secondly: It muſt not be laid too high; becauſe this draws all the Sap into the Plaſhes, and ſo cauſes but ſmall Shoots at the Bottom, and makes the *Hedge* ſo thin, that it will neither hinder the Cattle from going through, nor from cropping of it.

When the Shoot that is deſigned to be plaſhed is bent, give it a ſmall Cut with a Bill, half thro', ſloping a little downwards; and then weave it about the Stakes, and trim off the ſmall ſuperfluous Branches that ſtraggle too far out on both Sides of the *Hedges*.

If the Stubs are very old, cut them quite down, and ſecure them with good dead *Hedges* on both Sides, 'till the young Shoots are got up tall enough to plaſh, and plant new Sets in the void Spaces.

In making a *Hedge*, if it be ſet with *Crab* or *Apple Stocks*, it will be proper to leave one ſtanding uncut up at every ten, twelve, or twenty Feet, on both Sides the *Hedge*, if the Ground be your own: Which being done, they may be ſo ordered by pruning or ſtaking, that one may lean into one Ground, and the other into another, *&c.*

Theſe Stocks ſhould be prun'd up every Year, 'till they are brought out of the Reach of the Cattle; and then they may be grafted with the *Red-ſtreak*, *Gennet-moil*, or what other Fruit you pleaſe.

If the Stocks be of *Apple-kernels* they may ſtand ungrafted, and they will yield very good Cyder Fruit: But then ſuch Stocks as are not grafted, will be longer before they bear; and alſo, when you do graft, you may be certain of your Kind: But if you find a very natural Stock, which by Leaf, Shoot, and Bud appears likely, you may try it, and ſo you may have a new fine Fruit; and if you do not like it, you may graft it when you pleaſe.

As for the reſt of the *Hedge*, when it has ſhot three or four Years, you may lay it to make a Fence with; for the doing of which, take the following Directions:

1ſt: At every Laying to lay down ſome old Plaſhes; or, if the *Hedge* be thin, young ones: But they muſt be ſo laid, as to point with their Ends to the Ditch Side of the Bank, the Ends being kept low on the Bank: By being ſo ordered, they will the better thicken the Bottom of the *Hedge*, and keep up the Earth of the Bank.

2dly: To heighten the Bank every Time you lay Earth on it, ſo as to cover the Layers, all but the Ends; this Earth will very much help the *Quick*: And by heightning the Banks, and deepning the Ditch, you will render the Fence the better.

3dly: Not to cut the Plaſhes too much, but juſt ſo as they may bend down well; not to lay them too upright, as ſome do, but to lay them near to a Level: and by ſo doing, the Sap will the better break out at ſeveral Places, and not run ſo much to the Ends, as it will when they lie much upon the Slope.

If you have much Wood to ſpare, you may cut up great Part of thoſe that grow near the Ditch; but then you ought to hang the Bank with Buſhes, to prevent Cattle from cropping them the firſt Year: Theſe will ſhoot ſtrong, and ſecure the *Hedge*, keep up the Bank, and thicken the Bottom of the *Hedge*.

4thly: Take care to lay the *Hedge* pretty thick, and turn the Beard on the Ditch Side: But you muſt not let the Beard hang uncut, (though it makes a good Shew at the firſt making) but you muſt cut off all the ſtraggling Boughs within half a Foot of the *Hedge* on both Sides, and this will cauſe it to ſhoot ſtronger at theſe Places, and make the *Hedge* much the thicker.

5thly: If the Bank be high, make the *Hedge* ſo low, that it may but juſt ſerve for a Fence the firſt Year, for it will ſoon grow higher; and the lower the *Hedge* is made, the better the *Quick* will grow, and alſo the thicker at the Bottom: But Care muſt be taken to preſerve it from Cattle on the Field Side for the firſt Year that it is made.

6thly: If you would have a good *Hedge* or Fence, you ſhould fell it often; and at every Felling root out *Elder*, *Travellers-joy*, (which ſome call *Bull-bine*) *Briony*, &c. and do not leave too many high Standards or Pollards in it, tho' the *Elm* is one of the beſt; alſo too much dead Wood is not to be left in the Bottom of the *Hedges*, for that will choak the *Quick*; but if there be a Gap, the dead *Hedge* ſhould be made at a Diſtance.

HEDYPNOIS, [of Ἡδύπνοις, of ἡδὺς, *Sweet*, and πνοὴ, *Breath*, &c.] Trailing crooked-ſeeded Hawkweed.

The *Characters* are;

The Cup of the Flower is like a ſtriated Column, or a Melon: *The little Leaves of the Flower-cup, when the Flower is fallen off, embrace each of them one ſingle umbilicated Seed; but in the Middle of the little Head are other naked Seeds, which form an Head.*

The *Species* are;

1. HEDYPNOIS *annua. Tourn.* Trailing crooked-ſeeded Hawkweed, *or* common Hedypnois.
2. HEDYPNOIS *minor Cretica annua. J. Cor.* Annual Hedypnois from *Crete*.
3. HEDYPNOIS *annua, capite maximo. Boerh. Ind.* Annual Hedypnois, with a large Head.

Theſe Plants are ſeldom propagated, except in botanick Gardens, for the ſake of Variety, as being Plants of no great Beauty or Uſe. The firſt and third Species are found wild in the Southern Parts of *France*, in *Spain*, and *Italy*; but the ſecond Sort was brought from *Crete* by Monſ. *Tournefort*. Theſe may all be propagated by ſowing their Seeds towards the latter End of *March*, or the Beginning of *April*, in an open Situation, and a dry Soil, where they may remain to flower and ſeed, for they don't care to be tranſplanted: The Diſtance which theſe Plants ſhould be allowed muſt not be leſs than a Foot; and if the Soil be good, a Foot and an half aſunder will be full little enough; for they are very apt to ſpread to a great Diſtance; and their Branches trailing upon the Ground, would occaſion their rotting, were they to ſtand too cloſe to each other. Theſe Plants produce their Flowers in *June* and *July*; and their Seeds are perfected in *Auguſt*, when they ſhould be gathered, and preſerved for the ſucceeding Year.

HEDYSARUM, [of ἡδὺς, *ſweet*, and Ἄρον, Gr. the Herb *Arum*] *French* Honey-ſuckle.

The *Characters* are;

It hath papilionaceous Flowers, which are collected into an Head or Spike: The Pointal of the Flower, which riſes out of the Empalement, becomes a jointed undulated Pod; in each of which Joints is lodg'd a Kidney-ſhap'd Seed.

The *Species* are;

1. HEDYSARUM *clypeatum, flore ſuaviter rubente. H. Eyſt.* *French* Honey-ſuckle, with a delicate red Flower.
2. HEDYSARUM *clypeatum, flore albido. Tourn.* *French* Honey-ſuckle, with a whitiſh Flower.
3. HEDYSARUM *clypeatum minus, flore purpureo. Raii Hiſt.* Smaller *French* Honey-ſuckle, with a purple Flower.
4. HEDYSARUM *tryphyllum Canadenſe. Cornut.* Three-leaf'd *Canada French* Honey-ſuckle.
5. HEDYSARUM *annuum, ſiliqua aſpera undulata intorta. Tourn.* Annual *French* Honey-ſuckle, with a rough waved and wreathed Pod.
6. HEDYSARUM *Alpinum, ſiliqua lævi, flore purpuro-cæruleo. Tourn.* *Alpine French* Honey-ſuckle, with a ſmooth Pod and a blue purple Flower.
7. HEDYSARUM *Alpinum, ſiliqua lævi, flore albido. Tourn.* *Alpine French* Honey-ſuckle, with a ſmooth Pod, and a white Flower.
8. HEDYSARUM *minus diphyllum, flore luteo. Sloan. Cat.* Smaller two-leav'd *French* Honey-ſuckle, with a yellow Flower.

9. **Hedysarum** *triphyllum fruticoſum, flore purpureo, ſiliqua varie diſtorta. Sloan. Cat.* Three-leav'd ſhrubby *French* Honeyſuckle, with a purple Flower, and a variouſly diſtorted Pod.

10. **Hedysarum** *triphyllum fruticoſum minus. Sloan. Cat.* Smaller three-leav'd ſhrubby *French* Honey-ſuckle.

11. **Hedysarum** *triphyllum fruticoſum ſupinum, flore purpureo. Sloan. Cat.* Three-leav'd ſhrubby dwarf *French* Honeyſuckles with a purple Flower.

12. **Hedysarum** *annuum majus Zeylanicum, mimoſæ foliis. Tourn.* The greater annual *French* Honeyſuckle of *Zeylon*, with Leaves like the ſenſitive Plant.

13. **Hedysarum** *annuum minus Zeylanicum, mimoſæ foliis. Tourn.* The leſſer annual *French* Honey-ſuckle of *Zeylon*, with Leaves like the ſenſitive Plant.

14. **Hedysarum** *arboreſcens, foliis mimoſæ. Plum. Cat.* Shrubby *French* Honeyſuckle, with Leaves like the ſenſitive Plant.

15. **Hedysarum** *caule hirſuto, mimoſæ foliis alatis, pinnis acutis minimis gramineis. Sloan. Can. French* Honeyſuckle with a hairy Stalk, winged Leaves like the ſenſitive Plant, and ſmalleſt pointed graſs-like Wings.

16. **Hedysarum** *minimum procumbens, foliis pinnatis ſubrotundis, flore luteo. Houſt.* Smaller trailing *French* Honeyſuckle, with roundiſh winged Leaves, and a yellow Flower.

17. **Hedysarum** *triphyllum fruteſcens, foliis ſubrotundis & ſubtus ſericeis, flore purpureo. Houſt.* Three-leav'd ſhrubby *French* Honey-ſuckle, with roundiſh Leaves, which are ſilky underneath, and a purple Flower.

18. **Hedysarum** *triphyllum humile, flore conglomerato, calyce villoſo. Houſt.* Dwarf three-leav'd *French* Honey-ſuckle, with Flowers growing in Cluſters, and a hairy Cup.

19. **Hedysarum** *triphyllum procumbens, foliis rotundioribus & minoribus, ſiliquis tenuibus & intortis. Houſt.* Trailing three-leav'd *French* Honey-ſuckle, with ſmaller and rounder Leaves, and narrow intorted Pods.

20. **Hedysarum** *triphyllum, caule triangulari, foliis mucronatis, ſiliquis tenuibus intortis. Houſt.* Three-leav'd *French* Honey-ſuckle, with a triangular Stalk, pointed Leaves, and a narrow intorted Pod.

21. **Hedysarum** *triphyllum annuum erectum, ſiliquis intortis & ad extremitatem amplioribus. Houſt.* Three-leav'd annual upright *French* Honey-ſuckle, with intorted Pods, which are broad at their Extremity.

22. **Hedysarum** *triphyllum Americanum ſcandens, flore purpureo.* Three-leav'd climbing *American French* Honey-ſuckle, with a purple Flower.

The two firſt Species are very common in *England*, being propagated by the Gardeners near *London*, who ſupply the Markets with Plants and Flowers in the Spring of the Year.

The firſt four Sorts are propagated by ſowing their Seeds in *April*, in a Bed of light freſh Earth; and when the Plants come up, they ſhould be tranſplanted into other Beds of the like Earth, and in an open Situation, to about ſix or eight Inches Diſtance from each other, leaving a Path between every four Rows, to go between them to hough, and clear them from Weeds: In theſe Beds they may remain until *Michaelmas*; at which Time they may be tranſplanted into the large Borders of a Parterre or Pleaſure-Gardens, allowing them at leaſt two Feet Diſtance from other Plants, amongſt which they ſhould be interſpers'd, to continue the Succeſſion of Flowers, where they will make a very fine Appearance when blown, eſpecially the red Sort, which produces very handſome Flowers.

Theſe are tolerably hardy, and are ſeldom hurt but by extreme Cold, or great Rains. Moiſture, eſpecially in the Winter-ſeaſon, is very apt to rot their Roots, therefore they ſhould be planted in a dry Soil, and in a warm Situation; and in the Spring they may be remov'd to the Borders; where if they are much expoſed, or the Soil moiſt, they ſhould not be tranſplanted 'till *March*, juſt before they begin to ſhoot out their Flower-ſtems: But then they will not produce their Flowers ſo ſtrong as thoſe which are planted in Autumn.

In order to have a Succeſſion of theſe Plants, their Seeds ſhould be ſown every Spring; for the old Roots ſeldom continue long after they have flowered; and when they do remain, their Flowers are ſeldom ſo ſtrong as from young Roots. Their Seaſon of flowering is in *June* and *July*, and their Seeds are perfected in *Auguſt*.

The third Sort is preſerved in ſome Gardens for Variety; but the Flowers are not near ſo fair as thoſe of the two former: This requires the ſame Management as is directed for them.

The fourth Sort hath a perennial Root, which will abide many Years, if planted in a dry Soil. This is propagated by ſowing the Seeds in the Manner directed for the former: But when the Plants are come up two Inches high they ſhould be tranſplanted where they are to remain for good; for if they are not too thick in the Seed-bed, they may be ſuffered to remain there until the *March* following; at which Time they ſhould be carefully taken up, and tranſplanted into the Borders where they are deſigned to ſtand; for their Roots generally run down very deep, ſo that 'tis not ſafe to remove them often. This Plant produces its Flowers about the ſame Time of the Year as the former, and perfects its Seeds in Autumn; and the Roots will abide in the open Air very well, reſiſting the ſevereſt Cold, provided they are planted in a dry Soil.

The fifth, ſixth, and ſeventh Sorts are very hardy Plants, ſo will live in the open Air in this Country. Theſe are propagated by Seeds, which muſt be ſown in *March*, in a Bed or Border of light Earth, in the Place where they are deſigned to remain; becauſe, as they ſhoot their Roots deep into the Earth, ſo they do not bear tranſplanting well. When the Plants appear above Ground, they muſt be carefully cleared from Weeds, which, if ſuffered to grow, would ſoon overbear the young Plants, and deſtroy them. As the Plants advance in their Growth, they ſhould be thinned where they are too cloſe, leaving thoſe which are deſigned to flower, about a Foot or eighteen Inches apart. In dry Weather they will require ſome Water; and to keep them clear from Weeds, is all the Culture they want. In *July* they will flower, and, if the Autumn proves favourable, they will perfect their Seeds in *September*.

The eighth, ninth, tenth, eleventh, and fifteenth Sorts, were diſcovered by Sir *Hans Sloane*, Bart. in *Jamaica*, from whence the Seeds have been ſent into *England*, and have ſucceeded in ſeveral curious Gardens. Theſe are all of them annual Plants, notwithſtanding ſome of them grow ſhrubby, and will riſe to the Height of eight or nine Feet; for they periſh as ſoon as they have ripened their Seeds in the Country of their natural Growth.

The twelfth and thirteenth Sorts were brought from *Ceylon* by the learned Botaniſt, Dr. *Herman*, to the *Phyſick-Garden* at *Leyden*; but they are not peculiar to that Country, for I have received Seeds of both theſe Sorts from ſeveral Parts of *America*, which have flouriſhed in the *Phyſick-Garden* at *Chelſea*.

The fourteenth Sort was diſcovered by Father *Plumier*, in ſome of the *French* Settlements in *America*. The Seeds of this Sort were ſent me from *Campechy*, by the late Dr. *William Houſtoun*.

The ſixteenth, ſeventeenth, eighteenth, nineteenth, twentieth and twenty-firſt Sorts were diſcovered by the late Dr. *William Houſtoun* at *La Vera Cruz*, *Jamaica*, *Campechy*, and *Carthagena*, from which Places he ſent the Seeds and Specimens into *England*. The twenty-ſecond Sort I received from *South-Carolina*, which grew in the *Phyſick-Garden* at *Chelſea*.

Theſe are moſt of them annual Plants, and as they are Natives of warm Countries, ſo they require to be tenderly managed, to make them thrive in this Country. The Seeds of theſe Plants ſhould be ſown on a Hot-bed the Beginning of *March*; and when the Plants are about two Inches high, they muſt be carefully tranſplanted each into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark, being careful to ſhade them from the Sun until they have taken Root; after which Time they muſt have freſh Air admitted to them every Day by tilting the Glaſſes, in proportion to the Heat of the Weather: They muſt alſo be frequently refreſhed with Water, which will greatly promote their Growth. When the Plants have filled theſe Pots with their Roots, they ſhould be planted into larger; and as thoſe Sorts which grow upright, riſe to touch the Glaſſes of the Hot-bed, ſo they ſhould be removed into the Bark-bed in the Stove, or into a Glaſs-caſe, where they may have Room to grow. If theſe Plants are brought forward early in the Spring, they will begin to flower by the Beginning of *July*, and then they will have Time to ripen their Seeds before Winter; for if they are backward in flowering, they ſeldom perfect their Seeds in this Country.

The twelfth Sort rarely perfects Seed in *England*; for it generally grows to be five or ſix Feet high, and is always late before it flowers; but the thirteenth Sort will produce good Seeds every Year, if it is rightly managed.

The ſeventeenth and twenty-ſecond Sorts will abide two Years, provided they are placed in a warm Stove in Winter; and theſe Plants, when they are kept thro' the Winter, will flower early the following Summer, ſo that good Seeds may be obtained from them.

All theſe Plants afford an agreeable Variety in the Stove amongſt other exotic Plants in Autumn, when they are in Flower; ſo that they are preſerved by thoſe who are curious in Botany.

When an *Hedge* is of about eight or nine Years Growth, it will be proper to plaſh it: The beſt Time for this Work is either in *February*, or *October*.

When an *Hedge* is grown old, *i. e.* of about twenty or thirty Years Growth, and there are in it old Stubs, as well as new Shoots, the old Stubs ſhould be cut ſloping off within two or three Inches of the Ground; and the beſt and longeſt of the middle Size ſhould be left to lay down; and ſome of the ſtrongeſt, at the Height of five or ſix Feet, according as you deſign the Height of the *Hedge* to be, may be left to ſerve inſtead of Stakes; and freſh Stakes ſhould be put in thoſe Places where they are wanting: The *Hedge* ſhould be thinn'd, ſo as to leave on the Stubs only ſuch Shoots as are deſigned to be of Uſe, that there may be Room left to put a Spade in between them: The Ditch alſo ſhould be cleanſed, and each Side of the Slope kept as in a new Ditch: And where the Earth is waſh'd from the Roots of the Quick, or is hollow, face it anew with ſo much of the firſt Spit of Earth that is dug out of the Ditch, as there is Occaſion for; and lay what is dug out at the ſecond Spit, on the Top of the Bank; for if it be laid on the Side or Face of the Bank, it will ſlip into the Ditch again when Wet comes, and alſo take a great deal of the Bank along with it.

In planting *Quicks*, there are two Extremes to be avoided: The Firſt is, Laying it too low, and too thick; becauſe it makes the Sap run all into the Shoots, and leaves the Plaſhes without Nouriſhment; which, with the Thickneſs of the *Hedge*, kills them.

Secondly: It muſt not be laid too high; becauſe this draws all the Sap into the Plaſhes, and ſo cauſes but ſmall Shoots at the Bottom, and makes the *Hedge* ſo thin, that it will neither hinder the Cattle from going through, nor from cropping of it.

When the Shoot that is deſigned to be plaſhed is bent, give it a ſmall Cut with a Bill, half thro', ſloping a little downwards; and then weave it about the Stakes, and trim off the ſmall ſuperfluous Branches that ſtraggle too far out on both Sides of the *Hedges*.

If the Stubs are very old, cut them quite down, and ſecure them with good dead *Hedges* on both Sides, 'till the young Shoots are got up tall enough to plaſh, and plant new Sets in the void Spaces.

In making a *Hedge*, if it be ſet with *Crab* or *Apple Stocks*, it will be proper to leave one ſtanding uncut up at every ten, twelve, or twenty Feet, on both Sides the *Hedge*, if the Ground be your own: Which being done, they may be ſo ordered by pruning or ſtaking, that one may lean into one Ground, and the other into another, *&c.*

Theſe Stocks ſhould be prun'd up every Year, 'till they are brought out of the Reach of the Cattle; and then they may be grafted with the *Red-ſtreak*, *Gennet-moil*, or what other Fruit you pleaſe.

If the Stocks be of *Apple-kernels* they may ſtand ungrafted, and they will yield very good Cyder Fruit: But then ſuch Stocks as are not grafted, will be longer before they bear; and alſo, when you do graft, you may be certain of your Kind: But if you find a very natural Stock, which by Leaf, Shoot, and Bud appears likely, you may try it, and ſo you may have a new fine Fruit; and if you do not like it, you may graft it when you pleaſe.

As for the reſt of the *Hedge*, when it has ſhot three or four Years, you may lay it to make a Fence with; for the doing of which, take the following Directions:

1ſt: At every Laying to lay down ſome old Plaſhes; or, if the *Hedge* be thin, young ones: But they muſt be ſo laid, as to point with their Ends to the Ditch Side of the Bank, the Ends being kept low on the Bank: By being ſo ordered, they will the better thicken the Bottom of the *Hedge*, and keep up the Earth of the Bank.

2dly: To heighten the Bank every Time you lay Earth on it, ſo as to cover the Layers, all but the Ends; this Earth will very much help the *Quick*: And by heightning the Banks, and deepning the Ditch, you will render the Fence the better.

3dly: Not to cut the Plaſhes too much, but juſt ſo as they may bend down well; not to lay them too upright, as ſome do, but to lay them near to a Level: and by ſo doing, the Sap will the better break out at ſeveral Places, and not run ſo much to the Ends, as it will when they lie much upon the Slope.

If you have much Wood to ſpare, you may cut up great Part of thoſe that grow near the Ditch; but then you ought to hang the Bank with Buſhes, to prevent Cattle from cropping them the firſt Year: Theſe will ſhoot ſtrong, and ſecure the *Hedge*, keep up the Bank, and thicken the Bottom of the *Hedge*.

4thly: Take care to lay the *Hedge* pretty thick, and turn the Beard on the Ditch Side: But you muſt not let the Beard hang uncut, (though it makes a good Shew at the firſt making) but you muſt cut off all the ſtraggling Boughs within half a Foot of the *Hedge* on both Sides, and this will cauſe it to ſhoot ſtronger at theſe Places, and make the *Hedge* much the thicker.

5thly: If the Bank be high, make the *Hedge* ſo low, that it may but juſt ſerve for a Fence the firſt Year, for it will ſoon grow higher; and the lower the *Hedge* is made, the better the *Quick* will grow, and alſo the thicker at the Bottom: But Care muſt be taken to preſerve it from Cattle on the Field Side for the firſt Year that it is made.

6thly: If you would have a good *Hedge* or Fence, you ſhould fell it often; and at every Felling root out *Elder*, *Travellers-joy*, (which ſome call *Bull-bine*) *Briony*, &c. and do not leave too many high Standards or Pollards in it, tho' the *Elm* is one of the beſt; alſo too much dead Wood is not to be left in the Bottom of the *Hedges*, for that will choak the *Quick*; but if there be a Gap, the dead *Hedge* ſhould be made at a Diſtance.

HEDYPNOIS, [of Ἡδύπνοις, of ἡδὺς, *Sweet*, and πνοὴ, *Breath*, &c.] Trailing crooked-ſeeded Hawkweed.

The *Characters* are;

The Cup of the Flower is like a ſtriated Column, or a Melon: *The little Leaves of the Flower-cup, when the Flower is fallen off, embrace each of them one ſingle umbilicated Seed; but in the Middle of the little Head are other naked Seeds, which form an Head.*

The *Species* are;

1. **Hedypnois** *annua. Tourn.* Trailing crooked-ſeeded Hawkweed, *or* common Hedypnois.
2. **Hedypnois** *minor Cretica annua. J. Cor.* Annual Hedypnois from *Crete*.
3. **Hedypnois** *annua, capite maximo. Boerh. Ind.* Annual Hedypnois, with a large Head.

Theſe Plants are ſeldom propagated, except in botanick Gardens, for the ſake of Variety, as being Plants of no great Beauty or Uſe. The firſt and third Species are found wild in the Southern Parts of *France*, in *Spain*, and *Italy*; but the ſecond Sort was brought from *Crete* by Monſ. *Tournefort*. Theſe may all be propagated by ſowing their Seeds towards the latter End of *March*, or the Beginning of *April*, in an open Situation, and a dry Soil, where they may remain to flower and ſeed, for they don't care to be tranſplanted: The Diſtance which theſe Plants ſhould be allowed muſt not be leſs than a Foot; and if the Soil be good, a Foot and an half aſunder will be full little enough; for they are very apt to ſpread to a great Diſtance; and their Branches trailing upon the Ground, would occaſion their rotting, were they to ſtand too cloſe to each other. Theſe Plants produce their Flowers in *June* and *July*; and their Seeds are perfected in *Auguſt*, when they ſhould be gathered, and preſerved for the ſucceeding Year.

HEDYSARUM, [of ἡδὺς, *ſweet*, and Ἄρον, Gr. the Herb *Arum*] *French* Honey-ſuckle.

The *Characters* are;

It hath papilionaceous Flowers, which are collected into an Head or Spike: The Pointal of the Flower, which riſes out of the Empalement, becomes a jointed undulated Pod; in each of which Joints is lodg'd a Kidney-ſhap'd Seed.

The *Species* are;

1. **Hedysarum** *clypeatum, flore ſuaviter rubente. H. Eyſt.* *French* Honey-ſuckle, with a delicate red Flower.
2. **Hedysarum** *clypeatum, flore albido. Tourn.* *French* Honey-ſuckle, with a whitiſh Flower.
3. **Hedysarum** *clypeatum minus, flore purpureo. Raii Hiſt.* Smaller *French* Honey-ſuckle, with a purple Flower.
4. **Hedysarum** *tryphyllum Canadenſe. Cornut.* Three-leaf'd *Canada French* Honey-ſuckle.
5. **Hedysarum** *annuum, ſiliqua aſpera undulata intorta. Tourn.* Annual *French* Honey-ſuckle, with a rough waved and wreathed Pod.
6. **Hedysarum** *Alpinum, ſiliqua lævi, flore purpuro-cæruleo. Tourn.* *Alpine French* Honey-ſuckle, with a ſmooth Pod and a blue purple Flower.
7. **Hedysarum** *Alpinum, ſiliqua lævi, flore albido. Tourn.* *Alpine French* Honey-ſuckle, with a ſmooth Pod, and a white Flower.
8. **Hedysarum** *minus diphyllum, flore luteo. Sloan. Cat.* Smaller two-leav'd *French* Honey-ſuckle, with a yellow Flower.

9. Hedysarum *triphyllum fruticoſum, flore purpureo, ſiliqua varie diſtorta. Sloan. Cat.* Three-leav'd ſhrubby *French* Honeyſuckle, with a purple Flower, and a variouſly diſtorted Pod.

10. Hedysarum *triphyllum fruticoſum minus. Sloan. Cat.* Smaller three-leav'd ſhrubby *French* Honey-ſuckle.

11. Hedysarum *triphyllum fruticoſum ſupinum, flore purpureo. Sloan. Cat.* Three-leav'd ſhrubby dwarf *French* Honey-ſuckles with a purple Flower.

12. Hedysarum *annuum majus Zeylanicum, mimoſæ foliis. Tourn.* The greater annual *French* Honeyſuckle of *Zeylon*, with Leaves like the ſenſitive Plant.

13. Hedysarum *annuum minus Zeylanicum, mimoſæ foliis. Tourn.* The leſſer annual *French* Honey-ſuckle of *Zeylon*, with Leaves like the ſenſitive Plant.

14. Hedysarum *arboreſcens, foliis mimoſæ. Plum. Cat.* Shrubby *French* Honeyſuckle, with Leaves like the ſenſitive Plant.

15. Hedysarum *caule hirſuto, mimoſæ foliis alatis, pinnis acutis minimis gramineis. Sloan. Can.* *French* Honeyſuckle with a hairy Stalk, winged Leaves like the ſenſitive Plant, and ſmalleſt pointed graſs-like Wings.

16. Hedysarum *minimum procumbens, foliis pinnatis ſubrotundis, flore luteo. Houſt.* Smaller trailing *French* Honey-ſuckle, with roundiſh winged Leaves, and a yellow Flower.

17. Hedysarum *triphyllum fruteſcens, foliis ſubrotundis & ſubtus ſericeis, flore purpureo. Houſt.* Three-leav'd ſhrubby *French* Honey-ſuckle, with roundiſh Leaves, which are ſilky underneath, and a purple Flower.

18. Hedysarum *triphyllum humile, flore conglomerato, calyce villoſo. Houſt.* Dwarf three-leav'd *French* Honey-ſuckle, with Flowers growing in Cluſters, and a hairy Cup.

19. Hedysarum *triphyllum procumbens, foliis rotundioribus & minoribus, ſiliquis tenuibus & intortis. Houſt.* Trailing three-leav'd *French* Honey-ſuckle, with ſmaller and rounder Leaves, and narrow intorted Pods.

20. Hedysarum *triphyllum, caule triangulari, foliis mucronatis, ſiliquis tenuibus intortis. Houſt.* Three-leav'd *French* Honey-ſuckle, with a triangular Stalk, pointed Leaves, and a narrow intorted Pod.

21. Hedysarum *triphyllum annuum erectum, ſiliquis intortis & ad extremitatem amplioribus. Houſt.* Three-leav'd annual upright *French* Honey-ſuckle, with intorted Pods, which are broad at their Extremity.

22. Hedysarum *triphyllum Americanum ſcandens, flore purpureo.* Three-leav'd climbing *American French* Honey-ſuckle, with a purple Flower.

The two firſt Species are very common in *England*, being propagated by the Gardeners near *London*, who ſupply the Markets with Plants and Flowers in the Spring of the Year.

The firſt four Sorts are propagated by ſowing their Seeds in *April*, in a Bed of light freſh Earth; and when the Plants come up, they ſhould be tranſplanted into other Beds of the like Earth, and in an open Situation, to about ſix or eight Inches Diſtance from each other, leaving a Path between every four Rows, to go between them to hough, and clear them from Weeds: In theſe Beds they may remain until *Michaelmas*; at which Time they may be tranſplanted into the large Borders of a Parterre or Pleaſure-Gardens, allowing them at leaſt two Feet Diſtance from other Plants, amongſt which they ſhould be interſpers'd, to continue the Succeſſion of Flowers, where they will make a very fine Appearance when blown, eſpecially the red Sort, which produces very handſome Flowers.

Theſe are tolerably hardy, and are ſeldom hurt but by extreme Cold, or great Rains. Moiſture, eſpecially in the Winter-ſeaſon, is very apt to rot their Roots, therefore they ſhould be planted in a dry Soil, and in a warm Situation; and in the Spring they may be remov'd to the Borders; where if they are much expoſed, or the Soil moiſt, they ſhould not be tranſplanted 'till *March*, juſt before they begin to ſhoot out their Flower-ſtems: But then they will not produce their Flowers ſo ſtrong as thoſe which are planted in Autumn.

In order to have a Succeſſion of theſe Plants, their Seeds ſhould be ſown every Spring; for the old Roots ſeldom continue long after they have flowered; and when they do remain, their Flowers are ſeldom ſo ſtrong as from young Roots. Their Seaſon of flowering is in *June* and *July*, and their Seeds are perfected in *Auguſt*.

The third Sort is preſerved in ſome Gardens for Variety; but the Flowers are not near ſo fair as thoſe of the two former: This requires the ſame Management as is directed for them.

The fourth Sort hath a perennial Root, which will abide many Years, if planted in a dry Soil. This is propagated by ſowing the Seeds in the Manner directed for the former: But when the Plants are come up two Inches high they ſhould be tranſplanted where they are to remain for good; for if they are not too thick in the Seed-bed, they may be ſuffered to remain there until the *March* following; at which Time they ſhould be carefully taken up, and tranſplanted into the Borders where they are deſigned to ſtand; for their Roots generally run down very deep, ſo that 'tis not ſafe to remove them often. This Plant produces its Flowers about the ſame Time of the Year as the former, and perfects its Seeds in Autumn; and the Roots will abide in the open Air very well, reſiſting the ſevereſt Cold, provided they are planted in a dry Soil.

The fifth, ſixth, and ſeventh Sorts are very hardy Plants, ſo will live in the open Air in this Country. Theſe are propagated by Seeds, which muſt be ſown in *March*, in a Bed or Border of light Earth, in the Place where they are deſigned to remain; becauſe, as they ſhoot their Roots deep into the Earth, ſo they do not bear tranſplanting well. When the Plants appear above Ground, they muſt be carefully cleared from Weeds, which, if ſuffered to grow, would ſoon overbear the young Plants, and deſtroy them. As the Plants advance in their Growth, they ſhould be thinned where they are too cloſe, leaving thoſe which are deſigned to flower, about a Foot or eighteen Inches apart. In dry Weather they will require ſome Water; and to keep them clear from Weeds, is all the Culture they want. In *July* they will flower, and, if the Autumn proves favourable, they will perfect their Seeds in *September*.

The eighth, ninth, tenth, eleventh, and fifteenth Sorts, were diſcovered by Sir *Hans Sloane*, Bart. in *Jamaica*, from whence the Seeds have been ſent into *England*, and have ſucceeded in ſeveral curious Gardens. Theſe are all of them annual Plants, notwithſtanding ſome of them grow ſhrubby, and will riſe to the Height of eight or nine Feet; for they periſh as ſoon as they have ripened their Seeds in the Country of their natural Growth.

The twelfth and thirteenth Sorts were brought from *Ceylon* by the learned Botaniſt, Dr. *Herman*, to the *Phyſick-Garden* at *Leyden*; but they are not peculiar to that Country, for I have received Seeds of both theſe Sorts from ſeveral Parts of *America*, which have flouriſhed in the *Phyſick-Garden* at *Chelſea*.

The fourteenth Sort was diſcovered by Father *Plumier*, in ſome of the *French* Settlements in *America*. The Seeds of this Sort were ſent me from *Campechy*, by the late Dr. *William Houſtoun*.

The ſixteenth, ſeventeenth, eighteenth, nineteenth, twentieth and twenty-firſt Sorts were diſcovered by the late Dr. *William Houſtoun* at *La Vera Cruz*, *Jamaica*, *Campechy*, and *Carthagena*, from which Places he ſent the Seeds and Specimens into *England*. The twenty-ſecond Sort I received from *South-Carolina*, which grew in the *Phyſick-Garden* at *Chelſea*.

Theſe are moſt of them annual Plants, and as they are Natives of warm Countries, ſo they require to be tenderly managed, to make them thrive in this Country. The Seeds of theſe Plants ſhould be ſown on a Hot-bed the Beginning of *March*; and when the Plants are about two Inches high, they muſt be carefully tranſplanted each into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark, being careful to ſhade them from the Sun until they have taken Root; after which Time they muſt have freſh Air admitted to them every Day by tilting the Glaſſes, in proportion to the Heat of the Weather: They muſt alſo be frequently refreſhed with Water, which will greatly promote their Growth. When the Plants have filled theſe Pots with their Roots, they ſhould be planted into larger; and as thoſe Sorts which grow upright, riſe to touch the Glaſſes of the Hot-bed, ſo they ſhould be removed into the Bark-bed in the Stove, or into a Glaſs-caſe, where they may have Room to grow. If theſe Plants are brought forward early in the Spring, they will begin to flower by the Beginning of *July*, and then they will have Time to ripen their Seeds before Winter; for if they are backward in flowering, they ſeldom perfect their Seeds in this Country.

The twelfth Sort rarely perfects Seed in *England*; for it generally grows to be five or ſix Feet high, and is always late before it flowers; but the thirteenth Sort will produce good Seeds every Year, if it is rightly managed.

The ſeventeenth and twenty-ſecond Sorts will abide two Years, provided they are placed in a warm Stove in Winter; and theſe Plants, when they are kept thro' the Winter, will flower early the following Summer, ſo that good Seeds may be obtained from them.

All theſe Plants afford an agreeable Variety in the Stove amongſt other exotic Plants in Autumn, when they are in Flower; ſo that they are preſerved by thoſe who are curious in Botany.

HELENIASTRUM, Baſtard Elecampane.

The *Characters* are;

It hath a compound radiated Flower, conſiſting of many Florets, which are hermaphrodite, and of Semiflorets, which are female: The Ovaries ſtand on a naked Placenta, each bearing an antient Crown. All theſe Parts are included in a ſimple Empalement, which expands, and is cut almoſt to the Bottom in ſeveral Parts.

The *Species* are;

1. HELENIASTRUM *folio longiore & anguſtiore. Vaill. Mem.* Baſtard Elecampane, with a longer and narrower Leaf.
2. HELENIASTRUM *folio breviore & latiore. Vaill. Mem.* Baſtard Elecampane, with a broader and ſhorter Leaf.

Theſe Plants are both of them Natives of *America*; the Seeds of both Sorts I have received from *Virginia* and *New England*, where they grow wild in great Plenty in the Woods and other ſhady Places, where the Ground is moiſt. They may be propagated by Seeds, or by parting of their Roots; but the latter is generally practiſed in this Country, becauſe they ſeldom perfect their Seeds here; but if Seeds are procured from Abroad, they ſhould be ſown the Beginning of *March* on a warm Border of light Earth: And if the Seeds ſhould not come up the firſt Year, the Ground ſhould not be diſturbed; becauſe they often remain a whole Year under Ground, before the Plants appear: in which Caſe there is nothing more to be done, but to keep the Ground clear from Weeds, and wait until the Plants come up: when they appear, if the Seaſon proves dry, they muſt be often watered, which will greatly forward their Growth; and where the Plants come up too cloſe to each other, they ſhould be thinned and tranſplanted out into Beds a Foot aſunder every way, being careful to ſhade them until they have taken Root, as alſo to water them in dry Weather. In the Autumn theſe Plants will produce their Flowers, which will continue till the Froſt prevents them; and their Roots will abide many Years, and afford many Offſets, by which they may be increaſed.

The beſt Seaſon to tranſplant the old Roots, and to part them for Increaſe, is the Beginning of *March*, juſt before they begin to ſhoot; but if the Spring ſhould prove dry, they muſt be duly watered, otherwiſe they will not produce many Flowers the ſame Year. Theſe Plants ſhould not be removed oftener than every other Year; for, as they do not ſpread their Roots very wide, ſo they will continue within due Compaſs two Years very well. They delight in a Soil rather moiſt than dry, provided it be not too ſtrong, or holds the Wet in Winter: but if they are planted in a dry Soil, they muſt be often and plentifully watered in dry Weather, to make them produce Plenty of Flowers.

Theſe Plants generally riſe about three Feet and a half, or four Feet high; ſo ſhould be planted in the Middle of large Borders, intermixed with Flowers of the ſame Growth, where they will make a pretty Variety, becauſe they continue a long time in Flower: and as they require very little Care to cultivate them, ſo they deſerve a Place in every large Garden. Their Flowers reſemble thoſe of the ſmaller Kinds of *Sunflower*, and have been by ſome Botaniſts ranged in that *Genus*. The Time of their flowering is from *June*, until the Froſt ſtops them.

HELENIUM, Elecampane.

The *Characters* are;

It hath a radiated Flower, whoſe Florets are hermaphrodite, but the Semiflorets are female; both theſe are yellow; the Ovaries, which reſt on a naked Placenta, are crowned with Down: all theſe Parts are included in a ſcaly Cup. To theſe Notes may be added, the Leaves growing alternately on the Stalks, and the Flowers grow on the Top of the Branches.

The *Species* are;

1. HELENIUM *vulgare. C. B. P.* Common Elecampane.
2. HELENIUM *virgæ paſtoris folio, ſubtus incano & tomentoſo. Vaill. Mem.* Yellow Starwort, with a wild Teaſel-leaf, which is hoary and woolly underneath.
3. HELENIUM *villoſum, conyzæ folio, magno flore. Vaill. Mem.* Yellow hairy Starwort, with a fleabane Leaf, and a large Flower.
4. HELENIUM *conyzæ folio, prægrandi flore, calyce piloſiſſimo. Vaill. Mem.* Yellow Starwort, with a fleabane Leaf, and a larger Flower, and a very hairy Cup.
5. HELENIUM *Creticum, conyzæ folio, aſphodeli radice. Vaill. Mem.* Yellow Starwort of Crete, with a fleabane Leaf, and an aſphodel Root.
6. HELENIUM *paluſtre, folio longiori lanuginoſo. Vaill. Mem.* Marſh yellow Starwort, with a longer woolly Leaf.
7. HELENIUM *conyzæ folio lanuginoſo, radice odorâ. Vaill. Mem.* Yellow Starwort, with a woolly fleabane Leaf, and a ſweet-ſmelling Root.
8. HELENIUM *paluſtre villoſum odoratum, conyzæ folio. Vaill. Mem.* Hairy marſh ſweet-ſmelling Starwort, with a fleabane Leaf.
9. HELENIUM *montanum villoſum anguſtifolium, flore magno ſingulari. Vaill. Mem.* Hairy mountain yellow Starwort, with a narrow Leaf, and a large ſingle Flower.
10. HELENIUM *lanuginoſum anguſtifolium, ſummo caule ramoſo. Vaill. Mem.* Woolly yellow Starwort, with a narrow Leaf, and branching at the Top of the Stalks.
11. HELENIUM *pratenſe autumnale, conyzæ foliis caulem amplexantibus. Vaill.* Meadow yellow Starwort of the Autumn, with fleabane Leaves encompaſſing the Stalks, commonly called *Conyza media*.
12. HELENIUM *hirſutum, ſalicis folio. Vaill. Mem.* Hairy yellow Starwort, with a willow Leaf.
13. HELENIUM *montanum, ſalicis folio ſubtus incano. Vaill. Mem.* Mountain yellow Starwort, with a willow Leaf, which is hoary underneath.
14. HELENIUM *ſalicis folio glabro. Vaill. Mem.* Yellow Starwort, with a ſmooth willow Leaf.
15. HELENIUM *ſpirææ folio. Vaill. Mem.* Yellow Starwort, with a ciſtus Leaf, with a ſpirea Leaf.
16. HELENIUM *glabrum, myrti lato, ſerrato, cuſpidatoque folio. Vaill. Mem.* Smooth yellow Starwort, with a broad, ſawed, and pointed myrtle Leaf.
16. HELENIUM *ciſti folio non crenato, magno flore. Vaill. Mem.* Yellow Starwort, with a ciſtus Leaf, and a large Flower.
18. HELENIUM *lanuginoſum, piloſellæ foliis. Vaill. Mem.* Woolly yellow Starwort, with mouſe-ear Leaves.
19. HELENIUM *paluſtre ſubhirſutum, foliis calthæ. Vaill. Mem.* Marſh roughiſh yellow Starwort, with marygold Leaves.
20. HELENIUM *ſalicis folio, floribus parvis, fere umbellatis. Vaill. Mem.* Yellow Starwort, with a willow Leaf, and ſmall Flowers growing almoſt in an Umbel.
21. HELENIUM *paluſtre annuum, foliis criſpis. Vaill.* Annual marſh yellow Starwort, with curled Leaves, commonly called *Marſh Fleabane*.
22. HELENIUM *paluſtre annuum, hyſſopi foliis criſpis. Vaill. Mem.* Marſh annual yellow Starwort, with curled hyſſop Leaves.
23. HELENIUM *ramoſum, cauliculis ſparſis, calthæ arvenſis folio. Vaill. Mem.* Branching yellow Starwort, with ſparſe Stalks, and a field-marygold Leaf.
24. HELENIUM *Ægyptiacum tomentoſum & incanum, bellidioides, foliis criſpis. D. Lippi.* Hoary woolly *Egyptian* yellow Starwort, with curled daizy Leaves.
25. HELENIUM *Ægyptiacum tomentoſum & incanum, polii folio. D. Lippi.* Hoary woolly *Egyptian* yellow Starwort, with a mountain-poley Leaf.
26. HELENIUM *bellidioides, foliis amplis, aſphodeli radice. Vaill. Mem.* Yellow Starwort, with large daizy Leaves, and an aſphodel Root.
27. HELENIUM *perenne glabrum hyſſopifolium. Vaill. Mem.* Smooth perennial yellow Starwort, with an hyſſop Leaf.
28. HELENIUM *perenne glabrum, folio craſſo in ſummo tricuſpidato. Vaill. Mem.* Smooth perennial yellow Starwort, with a thick three-pointed Leaf.
29. HELENIUM *roriſmarini craſſis, obtuſis, confertiſque foliis. Vaill. Mem.* Yellow Starwort with thick blunt Leaves growing in Cluſters, commonly called *Golden Samphire*.
30. HELENIUM *ſaxatile, hyſſopi folio villoſo & glutinoſo. Vaill. Mem.* Rock yellow Starwort, with a hairy clammy hyſſop Leaf.

The firſt Sort is the true Elecampane, which is uſed in Medicine: it grows wild in moiſt Fields and Meadows in ſeveral Parts of *England*, and is pretty much cultivated in Gardens near *London*, to furniſh the Shops with the Roots, which is the only Part of the Plant in Uſe.

This Sort may be propagated by Seeds, or from ſmall Offſets, which are furniſhed with Buds on their Tops. If you would propagate it by Seeds, they ſhould be ſown on a moiſt Bed of light Earth ſoon after they are ripe; for if they are kept long out of the Ground, they will not ſucceed: theſe

Seeds generally remain in the Ground until the following Spring, when the Plants will begin to appear; at which time they muſt be carefully weeded, and if the Seaſon ſhould prove dry, they muſt be frequently watered, which will greatly promote their Growth. In this Bed the Plants ſhould remain till *Michaelmas* following, being careful to keep them conſtantly clear from Weeds during the Summer-ſeaſon. Then you ſhould prepare a Spot of Ground in proportion to the Number of Plants you have to tranſplant; which ſhould be well digged and cleanſed from the Roots of all noxious Weeds; then you muſt carefully fork up the Roots of the ſeedling Plants, ſo as not to break them; and with a Dibble they ſhould be planted in Rows about a Foot aſunder, and nine Inches Diſtance in the Rows: in the planting of theſe Roots, you muſt obſerve to make the Holes deep enough to receive them without being bent or broken, ſo that the Crown of the Roots may be juſt under the Surface of the Ground; then cloſe the Earth gently about them with your Feet. When the Plantation is finiſhed, there will be no farther Care required until the Spring, when the Plants begin to ſhoot; at which time the Ground ſhould be carefully houghed to clear it from Weeds, which Work muſt be repeated three or four times in the Spring; but always in dry Weather, which will intirely deſtroy the Weeds, if it be carefully performed; and when the *Elecampane* Plants have acquired Strength, they will keep the Weeds under, becauſe their Leaves being large, will ſpread and cover the Ground. If the Ground is good in which the Plants are placed, the Roots will be large enough to take up the *Michaelmas* following; but if the Ground is very poor, or too dry, they ſhould remain two Years after planting, before they are taken up for Uſe. *Note*, Theſe Roots ſhould not be taken up till the Leaves are decayed.

If you intend to propagate this Plant by Off-ſets, you muſt take them carefully off from the old Roots at *Michaelmas*, (which is the Time they are taken up for Uſe); ſo as to preſerve a good Bud to each Off-ſet; then plant them in a well prepared Spot of Ground, in the ſame Manner as hath been directed for the ſeedling Plants; and the following Summer they muſt be treated in the ſame Manner as thoſe.

All theſe Plants are ranged under the *Genus* of *Aſter*, by Dr. *Tournefort*, as agreeing in the Manner of their Flower and Seed with that Tribe: but as the Title of *Helenium* has been applied to the firſt *Species* by the Writers in Botany before his Time, and the outward Face of the Plant being very different from the *Starworts*, as alſo the Flowers being yellow; ſo Monſieur *Vaillant*, Profeſſor of Botany at *Paris*, has conſtituted a *Genus* by the Name of *Helenium*, and ſeparated all the *Species* which have yellow Flowers, from the *Aſters*, and placed them under this *Genus*; for which Reaſon I have added the *Engliſh* Name of *yellow Starwort* to all the *Species*.

The eleventh Sort is very common by the Sides of Ditches and Ponds in moſt Parts of *England*, ſo is ſeldom planted in Gardens; becauſe it creeps very much by the Root, and will ſoon overſpread a large Spot of Ground, when it has once taken Root. This Sort is commonly known by the Name of *Middle Fleabane*, in *England*.

The twenty-firſt Sort is alſo very common in *England*; this is an annual Plant, which ſows itſelf on moiſt Grounds, where the Water uſually ſtands in Winter; it flowers in *July* and *Auguſt*. This Plant is placed in the Catalogue of Simples annexed to the College Diſpenſatory, under the Title of *Conyza minor, flore globoſo*; it is alſo called *Pulicaria*, becauſe they ſay, the Smell of this Herb will drive away Fleas.

The twenty-ninth Sort grows on the Rocks and gravelly Shores by the Sea-ſide, in divers Parts of *England*, and is frequently gathered and brought to the Markets for *Samphire*, and pickled as ſuch. This is often diſtinguiſhed from the true *Samphire*, by the Title of *Golden Samphire*, becauſe the Flowers are yellow.

The other Sorts are not Natives of this Country, but are all of them hardy enough to thrive in the open Air, and ſeveral of them will grow in ſhady Places, and under the Drip of Trees; ſo that they deſerve to be propagated in the *Engliſh* Gardens. They are commonly propagated by parting of their Roots, becauſe they ſeldom produce good Seeds in this Country. The beſt Time to part their Roots is in Autumn, when their Stalks begin to decay; in doing of this, you ſhould be careful not to divide them too ſmall, as alſo to preſerve ſome good Buds to each Off-ſet. Theſe ſhould be planted in large Borders in the Pleaſure-Garden, intermixed with other hardy perennial Plants; where they will require no other Culture, but to keep them clear from Weeds, and to tranſplant the Roots every other Year, when they may be parted to increaſe them. In the Summer-time, when the Stalks are grown pretty high, they ſhould have Sticks thruſt into the Ground by each Root, and their Branches faſtened thereto with Baſs, to ſupport them; otherwiſe they are often broken down by heavy Rains, or ſtrong Winds, when they are in Flower; which renders them very unſightly in a neat Garden. Some of theſe Sorts begin to flower in *July*, and others ſucceed them, until the Froſts in Autumn put an End to their Flowering.

If theſe Plants are propagated by Seeds, it ſhould be ſown ſoon after it is ripe, in an open Bed of freſh Earth; for if the Seeds are kept out of the Earth till Spring, they ſeldom grow.

HELIANTHEMUM, [Ἡλιάνθεμον, of Ἥλιος *the Sun*, and Ἄνθος, *a Flower*] Dwarf-Ciſtus, *or* Little Sun-Flower.

The *Characters* are;

The Flower-cup conſiſts of three Leaves: The Flower, for the moſt part, conſiſts of five Leaves, which are placed orbicularly, and expand in form of a Roſe*: The Pointal of the Flower becomes a globular Fruit, which divides into three Parts, having three Cells, which are fill'd with roundiſh Seeds fix'd to ſmall Capillaments.*

The *Species* are;

1. Helianthemum *vulgare, flore luteo. J. B.* Common Dwarf Ciſtus, with a yellow Flower.
2. Helianthemum *vulgare, flore dilutiore. Tourn.* Common Dwarf Ciſtus, with a fainter Flower.
3. Helianthemum *Alpinum, folio piloſellæ minoris Fuchſii. J. B.* Hoary Dwarf Mountain Ciſtus, with Cat's-foot Leaves.
4. Helianthemum *Montanum, polii folio. Pluk.* Mountain Dwarf Ciſtus, with Poley Mountain Leaves.
5. Helianthemum *foliis majoribus, flore albo. J. B.* Great-leaf'd Dwarf Ciſtus, with a white Flower.
6. Helianthemum *album Germanicum. Tab. Icon.* White German Dwarf Ciſtus.
7. Helianthemum *flore albo, folio anguſto hirſuto. J. B.* White-flower'd Dwarf Ciſtus, with narrow hairy Leaves.
8. Helianthemum *ſaxatile, foliis & caulibus incanis oblongis, floribus albis Appennini montis. Mentz.* Rock Dwarf Ciſtus of the Appennines, with hoary oblong Leaves and Stalks, and white Flowers.
9. Helianthemum, *ſive Ciſtus humilis, folio Sampſuchi, capitulis valde hirſutis. J. B.* Dwarf Ciſtus, with a Marjoram Leaf, and very hairy Heads.
10. Helianthemum *folio Thymi, floribus umbellatis. Tourn.* Dwarf Ciſtus, with a Thyme Leaf, with Flowers growing in an Umbel.
11. Helianthemum, *polii folio ampliore, Luſitanicum. Tourn.* Portugal Dwarf Ciſtus, with large Poley Mountain Leaves.
12. Helianthemum *Germanicum luteum, Ciſti folio. Boerh.* German Dwarf Ciſtus, with a yellow Flower, and Ciſtus Leaf.
13. Helianthemum *ſalicis folio. Tourn.* Dwarf Ciſtus, with a Willow Leaf.
14. Helianthemum *Ledi folio. Tourn.* Dwarf Ciſtus, with a Ledum Leaf.
15. Helianthemum *flore maculoſo. Col.* Dwarf Ciſtus, with ſpotted Flowers.
16. Helianthemum *vulgare, flore albo. Tourn.* Common ſmall Sunflower, with a white Flower.
17. Helianthemum *ſerpilli folio, flore minore aureo odorato. Tourn.* Small Sunflower, with a Mother of Thyme Leaf, and a ſmaller golden ſweet-ſmelling Flower.
18. Helianthemum *anguſtifolium luteum. Tourn.* Yellow narrow-leav'd ſmall Sunflower.
19. Helianthemum *foliis myrti minoris, ſubtus incanis. Tourn.* Small Sunflower with leſſer Myrtle-leaves, which are hoary underneath.
20. Helianthemum *tenuifolium glabrum erectum, luteo flore. Tourn.* Narrow-leav'd ſmooth upright ſmall Sunflower.
21. Helianthemum *tenuifolium glabrum, luteo flore, per humum ſparſum. J. B.* Narrow-leav'd ſmooth ſmall Sunflower, ſpreading on the Ground with a yellow Flower.
22. Helianthemum *folio thymi incano. J. B.* Small Sunflower, with a hoary Thyme-leaf.
23. Helianthemum *thymi folio glabro. Tourn.* Small Sunflower, with a ſmooth Thyme-leaf.
24. Helianthemum *ad nummulariam accedens. J. B.* Small Sunflower reſembling Money-wort.
25. Helianthemum *foliis roriſmarini ſplendentibus ſubtus incanis. Tourn.* Small Sunflower, with ſhining roſemary Leaves hoary underneath.

26. Helianthemum *Maſſilienſe, coridis folio. Tourn.* Small Sunflower of Marſeilles, with a fair low heath-pine Leaf.

27. Helianthemum *polii folio ampliore, Luſitanicum. Tourn.* Portugueze Small Sunflower, with a larger Mountain Poley-leaf.

28. Helianthemum *polii folio anguſtiore, Luſitanicum. Tourn.* Portugueze Small Sunflower, with a narrow Poley Mountain-leaf.

29. Helianthemum *humilius Luſitanicum, halimi folio nigriore, magno flore luteo. Tourn.* Low Portugueze ſmall Sunflower, with a black ſea-purſlane Leaf, and a large yellow Flower.

30. Helianthemum *Algarvienſe, halimi folio, flore luteo punicante maculâ inſignito. Tourn.* Small Sunflower of *Algarve*, with a ſea-purſlane Leaf, and a yellow Flower ſpotted with Scarlet.

31. Helianthemum *Hiſpanicum, halimi folio rotundiore. Tourn.* Spaniſh ſmall Sunflower, with a round ſea-purſlane Leaf.

32. Helianthemum *Hiſpanicum, halimi folio anguſtiore. Tourn.* Spaniſh ſmall Sunflower, with a narrow ſea-purſlane Leaf.

33. Helianthemum *Hiſpanicum, halimi folio minimo. Tourn.* Spaniſh ſmall Sunflower, with the leaſt ſea-purſlane Leaf.

34. Helianthemum *Luſitanicum, mari folio incano, flore luteo. Tourn.* Portugueze ſmall Sunflower, with a hoary marum Leaf, and a yellow Flower.

35. Helianthemum *Luſitanicum, mari folio incano, capitulis valde hirſutis. Tourn.* Portugueze ſmall Sunflower, with a hoary marum Leaf, and very hairy Seed-veſſels.

36. Helianthemum *Luſitanicum, majoranæ folio, flore luteo punicante maculâ inſignito. Tourn.* Portugueze ſmall Sunflower, with a marjoram Leaf, and a yellow Flower ſpotted with Scarlet.

37. Helianthemum *Hiſpanicum, halimi folio ampliſſimo, incano & nervoſo. Tourn.* Spaniſh ſmall Sunflower, with a very large hoary ribbed Leaf.

38. Helianthemum *Hiſpanicum, anguſto folio, flore carneo. Tourn.* Spaniſh ſmall Sunflower, with a narrow Leaf, and a carnation Flower.

39. Helianthemum *Alpinum, oleæ folio ſubtus incano. Tourn.* Small Sunflower of the Alps, with an olive Leaf hoary underneath.

40. Helianthemum *Luſitanicum, bupleuri folio, flore maculato. Tourn.* Portugueze ſmall Sunflower, with a hares-ear Leaf, and a ſpotted Flower.

41. Helianthemum *Luſitanicum, globulariæ folio. Tourn.* Portugueze ſmall Sunflower, with a daizy Leaf.

42. Helianthemum *Hiſpanicum, origani folio ſubtus incano. Tourn.* Spaniſh ſmall Sunflower, with an origany Leaf hoary underneath.

43. Helianthemum *plantaginis folio, perenne. Tourn.* Perennial ſmall Sunflower, with a plantain Leaf.

44. Helianthemum *Hiſpanicum, folio minimo rotundiore. Tourn.* Spaniſh ſmall Sunflower, with a very ſmall round Leaf.

45. Helianthemum *Hiſpanicum, ocymi folio ſubtus incano. Tourn.* Spaniſh ſmall Sunflower, with a baſil Leaf, hoary underneath.

46. Helianthemum *pumilum, portulacæ marinæ folio argenteo. Tourn.* Dwarf ſmall Sunflower, with a ſilvery ſea-purſlane Leaf.

47. Helianthemum *Creticum, linariæ folio, flore croceo. Tourn. Cor.* Candy ſmall Sunflower, with a toad-flax Leaf, and a ſaffron Flower.

48. Helianthemum *Creticum annuum, lato plantaginis folio, flore aureo. Tourn. Cor.* Annual Candy ſmall Sunflower, with a broad plantain Leaf, and a golden Flower.

49. Helianthemum *Luſitanicum annuum, plantaginis folio, flore tricolore. Tourn.* Annual Portugueze ſmall Sunflower, with a plantain Leaf, and a three-coloured Flower.

50. Helianthemum *fruteſcens, folio majoranæ incano. Tourn.* Shrubby ſmall Sunflower, with a hoary marjoram Leaf.

51. Helianthemum *halimi folio breviore obtuſo. Tourn.* Small Sunflower, with a ſhorter blunt ſea-purſlane Leaf.

52. Helianthemum *folio halimi latiore mucronato. Tourn.* Small Sunflower, with a broader ſharp-pointed Leaf.

53. Helianthemum *Americanum fruteſcens, portulacæ folio. Plum. Cat.* Shrubby American ſmall Sunflower, with a purſlane Leaf.

The four firſt Sorts are found wild in ſeveral Parts of *Great Britain*; but the firſt is the moſt common of them all, and is found upon the Sides of dry Banks, and chalky Hills, in divers Parts of *England*. The twelve firſt Species are perennial Plants, which grow woody, but of low Stature, ſeldom riſing above a Foot high; the Branches, for the moſt part, trailing upon the Ground. Theſe Plants are very ornamental to a Garden, eſpecially if planted in a warm Poſition, and a dry Soil, where they will thrive and flower exceedingly, and are very proper to plant in ſloping Borders, or little Declivities, where few other Plants will thrive to Advantage: And altho' the Flowers of theſe Plants are of no great Beauty, yet the vaſt Quantities which are produced all over the Plants, for two Months together, render them worthy of a Place in every good Garden.

Theſe are all propagated by Seeds, (which the Plants annually furniſh in great Plenty) and ſhould be ſown in a warm Border of light freſh Earth in *March*, or the Beginning of *April*; and when the Plants are come up, they may be tranſplanted into Beds of the like Earth about four Inches aſunder, or ſomewhat more; in which Placethey may remain until *September*, when they ſhould be removed to the Places where they are to continue for good, obſerving to take them up with a good Ball of Earth to their Roots, otherwiſe they are ſubject to miſcarry.

They may alſo be propagated by planting Cuttings of any of the Sorts in *May*, in a Bed of light freſh Earth, obſerving to water and ſhade them until they have taken Root: Theſe alſo may remain in the Beds until *September*, when they ſhould be planted out, as was directed for the ſeedling Plants: But as they generally produce great Quantities of Seeds every Year, ſo there will ſeldom be Occaſion for propagating them any other Way: becauſe the ſeedling Plants are generally better than thoſe obtained from Cuttings; and it being more Trouble to propagate them by Cuttings, few People practiſe that Method.

The thirteenth, fourteenth, and fifteenth Sorts are annual Plants, and muſt be ſown every Year, or the Seeds ſuffer'd to fall; which, if the Ground be clear from Weeds, will come up, and abide the Winter, and flower early in the ſucceeding Summer; which is the ſureſt Method to obtain large Plants, eſpecially of the fifteenth Sort, of which, if the Seeds are ſown in the Spring, the Plants are apt to be very ſmall, and produce but few Flowers, and many times the Seeds will not come up at all; ſo that if you ſow them, it ſhould be done ſoon after they are ripe: The Flowers of this Sort are very beautiful, each Petal or Leaf having a deep purple Spot at the Bottom; and ſince it is a Plant which requires but very little Care, it is well worth keeping in a Garden.

The ſixteenth Sort is ſometimes found wild in *England*, and is only a Variety of the common Sort, differing only in the Colour of the Flower.

The twenty-ſeven Sorts next following grow wild in *Portugal*, *Spain*, the *South* of *France*, and the *Alps*. Theſe are all of them abiding Plants, which may be propagated by Seeds, in the Manner above directed, and if they are planted on a warm Border, or on a ſloping Bank, which is expoſed to the South, they will live in the open Air in this Country very well. As theſe Plants require very little Trouble to cultivate them, ſo they merit a Place in every large Garden; where if they are properly diſpoſed, they will afford an agreeable Variety.

Theſe Plants ſhould not be planted in a rich Soil; for they naturally grow on chalky Hills, or ſtony and gravelly Places, where they flower much better, and the Plants will continue longer, than when they grow in a rich Earth. As all theſe Plants are of humble Growth, and ſpread their Branches near the Ground; ſo they ſhould not be placed among tall-growing Plants, which will over-bear them, nor ſhould large Weeds be permitted to remain amongſt them, becauſe they will greatly weaken the Plants, and prevent their flowering.

The forty-fourth, forty-fifth, forty-ſixth, and forty-ſeventh Sorts, are of humbler Growth than the former Sorts, and ſeldom abide long; ſo that their Seeds ſhould be carefully ſaved, and ſown to raiſe a Supply of young Plants to preſerve their Kinds.

The 48th and 49th Sorts are annual Plants, ſo that their Seeds muſt be ſown every Seaſon, as directed for the thirteenth, fourteenth, and fifteenth Sorts. Theſe Seeds muſt be ſown in the Places where they are deſigned to remain, for the Plants do not ſucceed well when they are tranſplanted; all the Culture they require, is to keep them conſtantly clear from Weeds; and where the Plants are too near together, to thin them: With this Management they will produce their Flowers, and perfect their Seeds; which, if permitted to ſcatter, will produce young Plants in Autumn; which in a warm Situation will live thro' the Winter, and come early to flower the following Spring.

The fiftieth, fifty-firſt, and fifty-ſecond Sorts, are ſhrubby Plants, which riſe to the Height of four or five Feet; theſe are preſerved in Pots, and removed into the Green-houſe in Winter, being too tender to live in the open Air in this Country throughout the Year. They are uſually propagated by Cuttings, becauſe they ſeldom perfect Seeds in *England*, the beſt Time to plant the Cuttings, is in the Middle, or latter End of *June*, after the Plants have been expoſed in the open Air a ſufficient time to harden the Shoots; for if they are taken off ſoon after the Plants are removed out of the Green-houſe, the Shoots are generally too weak to make Cuttings. They ſhould be planted in a ſhady Border of light Earth, and frequently refreſhed with Water; in about two Months the Cuttings will be ſufficiently rooted to tranſplant, when they ſhould be carefully taken up with Balls of Earth, to their Roots, and each planted in a ſeparate ſmall Pot, filled with light freſh Earth, and placed in a ſhady Situation, until they have taken new Root; after which time they may be placed amongſt other hardy exotic Plants in a ſheltered Situation; where they may remain until the Middle of *October*, when they muſt be removed into the Green-houſe: during the Winter Seaſon, theſe Plants ſhould have as much free Air as poſſible in mild Weather, and will require to be often watered; and in the Summer Seaſon they muſt be removed into the open Air, and placed with other hardy exotic Plants, ſuch as *Myrtles*, *Geraniums*, &c. where they may be defended from ſtrong Winds; and in hot dry Weather, they muſt be plentifully watered: With this Management the Plants will thrive, and in *June*, *July* and *Auguſt*, they will flower, at which time they will make a pretty Appearance amongſt other exotic Plants.

As theſe Plants ſometimes produce good Seeds in *England*, or if their Seeds are procured from abroad; ſo thoſe Perſons who are deſirous to propagate them from Seed, ſhould ſow them the Beginning of *March*, on a very moderate Hot-bed, obſerving frequently to water the Bed to keep the Earth moiſt, otherwiſe the Seeds will not vegetate; and when the Plants appear above Ground, they ſhould have a large Share of Air, otherwiſe they will draw up too weak: they muſt alſo be kept clear from Weeds, and frequently refreſhed with Water; when the Plants are about two Inches high, they ſhould be each tranſplanted carefully into a ſmall Pot, filled with light freſh Earth, and plunged into a very moderate Hot-bed again, being careful to ſhade them from the Sun until they have taken Root; after which time they muſt be inured to bear the open Air by degrees, and in *June* they ſhould be removed out of the Hot-bed, and placed in a ſheltered Situation, and managed as hath been directed for thoſe Plants which were raiſed from Cuttings.

The fifty third Sort is much more tender than either of the former, being an Inhabitant of the warmeſt Parts of *America*. This was diſcovered by Father *Plumier*, in the *French* Settlements; and in the Year 1731. I had the Seeds of this Plant ſent me by the late Dr. *William Houſtoun*, from *La Vera Cruz*. This Sort grows about two Feet and a half, or three Feet high, and divides into many ſucculent Branches, which are beſet with thick ſucculent Leaves, ſomewhat reſembling thoſe of *Purſlane*: on the Top of the Branches is ſent forth a ſlender Stalk about a Foot long, which is garniſhed with beautiful ſcarlet Flowers, growing in a Spike; theſe Flowers are ſucceeded by tricapſular Seed-veſſels, which are full of ſmall Seeds.

This Sort, which was firſt procured by Seeds from abroad, has been ſince propagated by Cuttings, and diſperſed into ſeveral Parts of *Europe*. The beſt Seaſon for planting of theſe Cuttings, is in *July*; but they ſhould be cut from the Plant, and laid to dry, four or five Days before they are planted, otherwiſe they are very ſubject to rot. Theſe Cuttings ſhould be planted in Pots, filled with light freſh ſandy Earth, and plunged into a moderate Hot-bed, being careful to ſhade them from the Sun in the Heat of the Day, as alſo to refreſh them now and then with a little Water; but they muſt not be kept too moiſt, leſt that ſhould rot them. The Glaſſes of the Hot-bed ſhould alſo be raiſed every Day, to admit freſh Air to the Plants, in proportion to the Warmth of the Seaſon. With this Management the Cuttings will take Root in about a Month, when they may be expoſed to the Sun, giving them a proportionable Quantity of Air; but they ſhould remain in the Bed till the latter End of *September*, when they ſhould be removed into the dry Stove, and placed in the warmeſt Part, where they may have Sun and Heat. During the Winter Seaſon they ſhould be ſparingly watered, but in Summer they ſhould have a greater Share, as alſo a large Quantity of freſh Air; but they muſt conſtantly remain in the Stove.

HELIOTROPIUM, [Ἡλιοτρόπιον, of Ἥλιος, *the Sun*, and τρέπω, *to turn*] Turnſole.

The *Characters* are;

The Flower conſiſts of one Leaf, and is ſhaped like a Funnel, having its Center wrinkled and folded, and its Brim cut into ten Segments, alternately unequal: Theſe Flowers are collected into a long reflexed Spike, reſembling a Scorpion's Tail; each Flower is ſucceeded by four naked gibboſe Seeds.

The *Species* are;

1. Heliotropium *majus Dioſcoridis. C. B.* The great Turnſole of *Dioſcorides*.
2. Heliotropium *Americanum cœruleum, foliis Hormini. Acad. Reg. Sc.* Blue *American* Turnſole, with Clary Leaves.
3. Heliotropium *Americanum cæruleum, foliis Hormini anguſtioribus. H. L.* Blue *American* Turnſole, with narrower Clary Leaves.
4. Heliotropium *arboreſcens, folio teucrii, flore albo in capitula denſa congeſto. Boerh. Ind.* Tree-like Turnſole, with a Germander Leaf, and white Flowers growing in thick, ſhort Heads.
5. Heliotropium *Canarienſe arboreſcens, folio ſcorodoniæ. Hort. Amſt.* *Canary* Tree-like Turnſole, with a Wood-ſage Leaf.

The firſt, ſecond, and third Kinds are annual Plants: The firſt is very hardy, and is better preſerv'd in a Garden, by ſuffering the Seeds to fall when ripe, which will come up in the ſucceeding Spring much better than when preſerv'd and ſown with Care; for it rarely happens that thoſe which are ſown in the Spring do grow; ſo that if it be intended to be had in a different Place from where the Plants grew the preceding Year, the Seeds ought to be ſown ſoon after they are ripe; which ſhould be in the Place where they are to remain; for theſe Plants ſeldom thrive well when tranſplanted, eſpecially if it be not perform'd while the Plants are young.

This Plant produces its Flowers in *June*, and the Seeds ripen in *Auguſt*.

The ſecond and third Sorts muſt be ſown upon a Hot-bed in the Spring, and managed as was directed for the *Cyanus Turcicus*, (to which the Reader is deſired to turn, to ſave Repetition); for if they are not brought forward in the Spring, they ſeldom perfect their Seeds: There is no great Beauty in theſe two Plants, nor are they often cultivated but in botanick Gardens for Variety-ſake.

The fourth and fifth Sorts grow to be large ſhrubby Plants: Theſe are propagated by planting Cuttings of them, in any of the Summer Months, in a Bed of light Earth, obſerving to ſhade and water them until they have taken Root; and in *Auguſt* they ſhould be tranſplanted into Pots fill'd with light freſh Earth, which ſhould be placed in a ſhady Situation until the Plants are rooted in the Pots, when they may be removed into the open Air amongſt *Myrtles*, *Jaſmines*, &c. where they may remain until *October*; at which Time they ſhould be removed into the Green-houſe, where they ſhould be placed ſo as to have as much free Air as poſſible, and will require frequent Waterings.

The fifth Sort produces Flowers every Summer: But I have never yet ſeen any on the fourth Sort, altho' it is by much the larger Plant.

HELLEBORE. *Vide* Helleborus.

HELLEBORINE; Baſtard Hellebore.

The *Characters* are;

It hath a fibroſe Root: The Leaves are broad and nervous, ſomewhat like thoſe of the White Hellebore*: The Flowers, which grow upon a ſhort Foot-ſtalk, are collected into a Spike, each conſiſting of ſix diſſimilar Leaves: The Ovary becomes a Fruit very like that of the* Orchis.

The *Species* are;

1. Helleborine *latifolia montana. C. B. P.* Common Baſtard Hellebore.
2. Helleborine *altera, atro-rubente flore. C. B. P.* Baſtard Hellebore, with a blackiſh Flower.
3. Helleborine *flore albo. Ger.* White-flower'd Baſtard Hellebore.
4. Helleborine *flore rotundo, ſive Calceolus. C. B. P.* Lady's Slipper.
5. Helleborine *Virginiana, flore rotundo luteo. Baniſter.* *Virginian* Lady's Slipper, with a yellow Flower.

6. **Helleborine** *Canadenſis, ſive Calceolus Mariæ. Icon. Robert.* Canada Lady's Slipper.

7. **Helleborine** *latifolia, flore albo clauſo. Raii Syn.* Broad-leav'd Baſtard Hellebore, with a white ſhut Flower.

8. **Helleborine** *foliis prælongis anguſtis acutis. Raii Syn.* Baſtard Hellebore, with longer narrow pointed Leaves.

9. **Helleborine** *paluſtris noſtras. Raii Syn.* Marſh Baſtard Hellebore.

10. **Helleborine** *montana anguſtifolia purpuraſcens. C. B. P.* Narrow-leav'd purple mountain Baſtard Hellebore.

11. **Helleborine** *Virginiana, ophioglſſi folio. D. Baniſt.* Baſtard Hellebore of *Virginia*, with an adders-tongue Leaf.

12. **Helleborine** *Mariana, bupleuri anguſtiſſimo folio, purpuraſcente flore, caule aphyllo. Pluk.* Baſtard Hellebore of *Maryland*, with a very narrow Leaf, like that of Hares-ear, a purpliſh Flower, and a Stalk without a Leaf.

13. **Helleborine** *Mariana, flore pallide purpureo, trianthophoros. Pluk. Mantiſſ.* Baſtard Hellebore of *Maryland*, with pale purple Flowers, growing three on a Stalk.

14. **Helleborine** *Mariana monanthos, flore longo purpuraſcente liliaceo. Pluk. Mantiſſ.* Baſtard Hellebore of *Maryland*, with one long purpliſh lily-ſhaped Flower.

15. **Helleborine** *Virginia, flore rotundo magno ex purpureo albicante. Baniſt. Cat.* Baſtard Hellebore of *Virginia*, with a large round Flower of a purpliſh white Colour.

16. **Helleborine** *foliis liliaceis, aſphodeli radice. Plum. Cat.* Baſtard Hellebore of *America*, with Leaves like the Lily, and an aſphodel Root.

17. **Helleborine** *purpurea, tuberoſâ radice. Plum. Cat.* Purple Baſtard Hellebore, with a tuberoſe Root.

18. **Helleborine** *Americana, foliis longiſſimis, tuberoſâ radice. American* Baſtard Hellebore, with very long Leaves, and a tuberoſe Root, commonly called, *the Flower of the Holy Ghoſt.*

19. **Helleborine** *graminea, foliis rigidis carinatis. Plum. Cat.* Graſs-like Baſtard Hellebore, with ſtiff Leaves.

The firſt ſix Sorts are Natives of Woods and ſhady Places: The four firſt mentioned are found in the Woods of *Yorkſhire, Lancaſhire*, and other Northern Countries in *England:* But the fifth and ſixth are Natives of *America*, from whence ſome of the Plants have been ſent into *England*, which thrive, and produce Flowers very well every Year. There is no other Method to obtain theſe Plants, but by ſearching them out in their natural Places of Growth, and taking up their Roots, with a large Ball of the natural Soil to 'em, and then to tranſplant them into a ſhady Place in the Garden, and in a ſtrong undung'd Soil: Theſe are very pretty Ornaments to ſmall Wilderneſſes; where, if the Ground between the Trees be planted with theſe, and other common Flowers which grow naturally in Woods, it will render ſuch Places very agreeable: And as theſe require little other Culture than to preſerve them from being over-run with Weeds; ſo the only Expence is in the firſt procuring them, which is eaſily effected in many Parts of *England.* The beſt Seaſon for tranſplanting them is in *May*, ſoon after they appear above-ground.

The ſeventh, eighth, and ninth Sorts, grow wild in many Parts of *England*; the tenth Sort has been found in *Ireland*, and is pretty common in other Parts of *Europe.* Theſe may be tranſplanted into Gardens, from the Places of their natural Growth; either in the Spring, ſoon after they appear above Ground, or in Autumn, when their Leaves begin to decay; but if they are tranſplanted in Spring, there ſhould be great Care had, to preſerve a large Ball of Earth to their Roots, otherwiſe they will not ſucceed. Theſe Plants ſhould be planted in ſhady moiſt Places, and in a ſtrong undunged Soil, where they will continue many Years, and produce their Flowers toward the latter Part of Summer.

The eleventh, twelfth, thirteenth, fourteenth and fifteenth Sorts, are Natives of *Virginia, Maryland*, and *New England*; from which Places ſome of their Roots have been brought into *England.* The beſt Method to obtain theſe Kinds, is to procure ſome of their Roots to be taken up with Balls of Earth, and planted into Tubs of the natural Soil in which they grew, as cloſe together as poſſible; theſe Tubs ſhould remain in the Country, until the Leaves of the Plants begin to decay, when they may be put on board the Ships, and ſent over; for as the Roots will then be in a State of Inaction, ſo they will be in leſs Danger of ſuffering in their Paſſage, than if they were in a vigorous growing State, and will require very little (if any) Water. Theſe Plants may be planted out of the Boxes into ſmall Wilderneſs Quarters, where they will abide the Cold of the Winter very well, and produce their Flowers in Summer.

The ſixteenth and ſeventeenth Sorts were diſcovered by Father *Plumier*, in the *French* Settlements in *America*; both theſe Sorts were ſent by the late Dr. *William Houſtoun* from *Jamaica*, where they grow in the Woods and ſhady Places in great Plenty. The ſeventeenth Sort was alſo ſent from the *Bahama Iſlands*, to Mr. *Peter Collinſon*, and hath been ſince diſtributed to many curious Perſons in *England.* This is a very curious Plant, and deſerves a Place in the Stove, becauſe it produces a moſt beautiful Spike of purple Flowers every Year. This and the former Sort are propagated by Off-ſets, which they ſend forth plentifully; the beſt Seaſon for tranſplanting the Roots, and taking off the Off-ſets, is in the Beginning of *February*, juſt before they begin to ſhoot. Theſe Roots ſhould be planted in Pots, filled with light rich Earth, and then plunged into the Tan in the Stove, obſerving to refreſh the Earth with Water now and then; but it muſt not be given to them in great Quantities, until they have ſent forth their Leaves; for too much Moiſture will rot theſe Roots, while they are in an unactive State. Theſe Plants ſhould conſtantly be kept in the Bark-bed in the Stove, otherwiſe they will not flower: During the Summer-ſeaſon, they will require a larger Share of Moiſture, and in hot Weather, they ſhould have a large Share of freſh Air; but in Winter they muſt be kept warm, otherwiſe the Roots will periſh. With this Management the Plants will thrive exceedingly, and produce their beautiful Flowers in *Auguſt.* The Roots of theſe Plants ſhould not be diſturbed in Winter; for altho' their Leaves decay in Autumn, and their Roots remain unactive, yet if they are taken up and kept out of the Ground, they are very apt to ſhrink, unleſs great Care be taken of them. The ſeventeenth Sort was by Accident procured in *England*, the Root being ſent over as a Specimen of the Plant, which was dried and ſent to Mr. *Collinſon*; he took off the Root, and had it planted in the Stove at Sir *Charles Wager*'s Garden; it grew and flowered; from which Root there has been a great Number produced. This Sort produces a Spike of Flowers near two Feet long, which being of a bright purple Colour, make a fine Appearance in the Stove.

The eighteenth Sort grows in great Plenty on the Sides of the Road between *Porto Bello* and *Panama*, in the *Spaniſh Weſt-Indies*, in ſhady Places, and on a ſtony Soil. The *Spaniards* ſay, it is only to be found in this Place, and that it cannot be tranſplanted to any other Part of the Country, ſo as to grow. The Flowers of this Plant reſemble a *Dove*, from whence the *Spaniards* gave it the Name of the *Holy Ghoſt.* Some of theſe Roots were ſent to *England* by Mr. *Robert Millar*, Surgeon, who was on the Spot where they grow; ſome of theſe Roots are yet alive in *England*, but have not as yet produced any Flowers. This and the nineteenth Sort, are both very tender Plants; ſo, if they are brought into *England*, they muſt be treated very tenderly, their Roots ſhould be planted in Pots, filled with a ſandy Soil mixed with Lime Rubbiſh; and then plunged into a Hot-bed of Tanners-bark, being careful not to give them too much Water, until they begin to ſhoot; after which Time they ſhould be frequently watered. During the Summer-ſeaſon theſe Plants muſt have freſh Air admitted to them; but in Winter they muſt have a very warm Situation. Theſe put forth their green Leaves in *May*, which continue till Autumn, when they decay; ſo that the Roots remain inactive above ſix Months.

There are many other Sorts of theſe Plants, which are Natives of *America*; but the greater Part of them growing on Trees, cannot be cultivated in Gardens; ſo it is needleſs to enumerate them in this Place.

HELLEBOROIDES HYEMALIS. *Vide* Aconitum Hyemale.

HELLEBORO-RANUNCULUS; Globe-Ranunculus, *vulgo.*

The *Characters* are;

It hath ſingle, round, circumſcribed Leaves like the Ranunculus: *The Cup of the Flower conſiſts of five ſmall Leaves of the ſame Colour with the Flower: The Flower conſiſts of many Leaves growing in form of a* Ranunculus, *having many Stamina in the Centre: The Fruit conſiſts of many ſmall Cells, which are collected into a Head, each containing many Seeds.*

We have but one *Species* of this Plant, which is;

Helleboro-Ranunculus *flore luteo globoſo. Boerh. Ind.* The Globe-Flower, *or* Lockergowlans.

This Plant is found wild in the North Parts of *England* and *Wales* in great Plenty: It is propagated by parting the Roots in Autumn, which ſhould be planted in a moiſt ſhady Situation, where they will thrive and flower exceedingly, and require very little Care, except to keep them clear from Weeds, and parting the Roots every other Year; for if they are permitted to continue too long unremov'd, the Flowers will not be ſo large, nor in ſo great Quantity.

HELLEBORUS, [Ἑλλέβορος] Black Hellebore, *or* Chriſtmas Flower.

The *Characters* are ;

It hath a digitated Leaf: The Flower conſiſts of ſeveral Leaves, which are placed orbicularly, and expand in form of a Roſe: In the Centre of the Flower riſes the Pointal, which is incompaſſed about the Baſe with ſeveral little Horns lying between the Chives and Petals, which afterwards turn to a Fruit, in which the membranaceous Husks are gathered, as it were, into a little Head, ending, for the moſt part, in a Horn, opening lengthwiſe, and, for the moſt part, full of roundiſh or oval Seeds.

The *Species* are ;

1. Helleborus *niger fœtidus. C. B. P.* Stinking Black Hellebore, Bear's foot, *or* Settlewort.
2. Helleborus *niger hortenſis, flore viridi. C. B. P.* Green-flower'd Black Hellebore, *or* Bear's-foot.
3. Helleborus *niger, flore albo, etiam interdum valde rubente. J. B.* True Black Hellebore, *or* Chriſtmas Roſe.
4. Helleborus *niger trifoliatus. Hort. Farn.* Trifoliated Black Hellebore.
5. Helleborus *niger, flore roſeo, minor Belgicus. H. R. Blæſ.* Small Belgick Black Hellebore.
6. Helleborus *niger hortenſis alter. C. B. P.* The other garden black Hellebore.
7. Helleborus *niger, amplioribus foliis. Tourn.* Black Hellebore, with larger Leaves.
8. Helleborus *niger autumnalis, flore maximo. H. R. Par.* Autumnal black Hellebore, with a very large Flower.
9. Helleborus *niger, ſanguineo folio. Bocc. Muſ.* Black Hellebore, with a bloody Leaf.
10. Helleborus *niger orientalis, ampliſſimo folio, caule prœalto, flore purpuraſcente. Tourn. Cor.* Eaſtern black Hellebore, with a very large Leaf, a tall Stalk, and a purpliſh Flower.

The two firſt Species are found wild in the Woods in divers Parts of *England* ; but the third, fourth, and fifth Sorts are brought from other Countries, which do thrive as well with us in the open Air, as thoſe that are Natives. The two firſt Sorts being Wood Plants, thrive much better when planted in ſhady moiſt Places, than when they are planted in a warmer Situation, and too much expoſed to the Sun: And as they produce their Flowers in the Middle of Winter, when few other Plants appear ; ſo they deſerve a Place in ſmall Wilderneſs Quarters, Avenues, and ſhady Borders, where they will flouriſh exceedingly, and, if ſuffer'd to ſhed their Seeds, will ſoon furniſh a Garden with Plants enough ; and this is the eaſieſt and beſt Method to propagate them.

The 3d, 4th, and 5th Sorts are propagated either from Seeds, or by planting of their Roots: the beſt Seaſon for this Work is in *February*, when you may divide the Roots into ſmall Heads, and plant them in a Situation where they may have the Morning Sun only 'till ten o' Clock ; for if they are too much expoſed to the great Heats of the Sun, they will not thrive: Theſe ſhould alſo have a moiſt light Soil ; but the Ground ſhould not have Dung in it, which is very ſubject to rot the Roots of theſe Plants.

If you propagate them by Seeds, they ſhould be ſown ſoon after they are ripe, which is commonly in *May*, in a Border expoſed to the Morning Sun, where the Plants will come up the Spring following, and ſhould be kept clear from Weeds ; which, if ſuffer'd to grow, would ſoon deſtroy the young Plants: In this Border they ſhould remain until the *February* following, at which Time they ſhould be tranſplanted into another Border to the Diſtance of ſix Inches ſquare, obſerving to keep them conſtantly clear from Weeds ; and in one Year after planting out, they will flower, and may then be removed to the Places where they are to remain for good.

There are great Doubts whether any of theſe Species be the true *Hellebore* of the Antients ; tho' Monſ. *Tournefort*, and ſome other Travellers affirm, that the third Species is it: But yet the *Germans* uſe the *Adonis, Hellebori radice, buphthalmi flore*, for the *Hellebore* ; and many other People believe it to be a Plant different from both theſe: But it is hoped that we ſhall ſhortly know who are in the right.

The laſt five Plants are not Natives of this Country, but are hardy enough to bear the Cold of our Winters very well in the open Air: They require a ſhady Situation, and thrive beſt in a ſtrong loamy Soil ; for if the Ground is hot and dry, in which they are planted, they will not thrive or produce any Flowers. They may be propagated by parting of their Roots, or from Seeds, as is directed for the former Species.

HELLEBORUS ALBUS. *Vide* Veratrum.

HELMET-FLOWER, *or* **MONK'S-HOOD.** *Vide* Aconitum.

HEMEROCALLIS. *Vide* Lilium.

HEMIONITIS [Ἡμιονῖτις, of Ἡμίονος, *a Mule*, q. d. *Mulewort*, becauſe this Plant was believ'd to be as barren as a Mule] Moon-Fern.

This is a Plant which is ſeldom propagated in Gardens ; therefore I ſhall not trouble the Reader with any Account of it more than this, that whoever hath a mind to cultivate it, may ſee full Directions for that Purpoſe under the Article *Lingua Cervina*, to which this Plant is nearly ally'd, and delights in the ſame Situation and Culture.

HEPATICA, [Ἡπατῖτις, of Ἧπαρ, *the Liver* ; ſo call'd, becauſe the Leaves of this Plant are divided into Lobes, like the Liver, (but it does not at all take its Name from its Uſe ; for it is of no Virtue againſt Diſeaſes of the Liver, as many have erroneouſly imagined) ; and *Trifolia*, from its Similitude thereto] Noble Liverwort.

The *Characters* are ;

The Root is fibroſe and perennial: The Leaf conſiſts of three Lobes growing on a Pedicle which ariſes from the Root: The Pedicle of the Flower is naked and ſingle, ariſing from the Root: The Cup of the Flower is, for the moſt part, compoſed of one Leaf, which is ſometimes cut into three or four deep Diviſions: The Flower conſiſts of many Leaves, which expand in form of a Roſe*: The Fruit is globular, conſiſting of one ſingle Cell, which is curvated, as in the* Leſſer Celandine.

The *Species* are ;

1. Hepatica *trifolia, cœruleo flore. Cluſ.* The ſingle blue Hepatica, *or* Noble Liverwort.
2. Hepatica *trifolia, flore cœruleo pleno. Cluſ.* The double blue Hepatica, *or* Noble Liverwort.
3. Hepatica *trifolia, flore albo ſimplici. Boerh. Ind.* The ſingle white Hepatica, *or* Noble Liverwort.
4. Hepatica *trifolia, rubro flore. Cluſ.* Single red Hepatica, *or* Noble Liverwort.
5. Hepatica *trifolia, flore rubro pleno. Boerh. Ind.* Double red, *or* Peach-colour'd Hepatica.

Theſe Plants are ſome of the greateſt Beauties of the Spring: Their Flowers are produced in *February* and *March* in great Plenty, before the green Leaves appear, and make a very beautiful Figure in the Borders of the Pleaſure-Garden, eſpecially the Double Sorts, which do commonly continue a Fortnight longer in Flower than the ſingle Kinds, and the Flowers are much fairer. I have ſeen the double white Kind often mention'd in Books, but could never ſee it growing ; tho' I don't know but ſuch a Flower might be obtain'd from Seeds of the ſingle white, or blue Kinds. I have ſometimes known the double blue Sort produce ſome Flowers in Autumn which were inclining to white ; and thereby ſome People have been deceiv'd, who have procur'd the Roots at that Seaſon, and planted them in their Gardens, but the Spring following their Flowers were blue, as before: And this is a common Thing when the Autumn is ſo mild as to cauſe them to flower. But whether the double white Sort, mention'd in the Books, was only this accidental Alteration in the Colour of the Flower, I can't ſay ; tho' it ſeems very probable it was, ſince I never could hear of any Perſon who ever ſaw the double white Sort flower in the Spring.

The ſingle Sorts produce Seeds every Year, whereby they are eaſily propagated, and alſo new Flowers may be that Way obtain'd. The beſt Seaſon for ſowing of the Seeds is in the Beginning of *Auguſt*, either in Pots or Boxes of light Earth, which ſhould be placed ſo as to have only the Morning Sun until *October*, when they ſhould be removed into the full Sun, to remain during the Winter-ſeaſon: But in *March*, when the young Plants will begin to appear, they muſt be removed again to a ſhady Situation, and in dry Weather ſhould be frequently watered ; and about the Beginning of *Auguſt* they will be fit to be tranſplanted ; at which Time you ſhould prepare a Border, facing the Eaſt, of good freſh loamy Earth, into which you ſhould remove the Plants, placing them at about ſix Inches Diſtance each Way, cloſing the Earth pretty faſt to their Roots, to prevent the Worms from drawing them out of the Ground, which they are very apt to do at that Seaſon, and in the Spring following they will begin to ſhew their Flowers: But it will be three Years before they flower ſtrong, and 'till then you cannot judge of their Goodneſs; when, if you find any double Flowers, or any of a different Colour from the common Sorts, they ſhould be taken up and tranſplanted into the Borders of the Flower-Garden, where they ſhould continue at leaſt two Years before they are taken up, or parted; for it is remarkable in this Plant, that where they are often remov'd and parted, they are very ſubject to die; whereas, when they are permitted to remain undiſturb'd for many Years, they will thrive exceedingly, and become very large Roots.

The double Flowers, which never produce Seeds, are propagated by parting their Roots, which ſhould be done in *March*, at the Time when they are in flower: But you ſhould be careful not to ſeparate them into very ſmall Heads; nor ſhould they be parted oftener than every third or fourth Year, if you intend to have them thrive, for the Reaſon before given. They delight in a ſtrong loamy Soil, and in an Eaſtern Poſition, where they may have only the Morning Sun; tho' they will grow in almoſt any Aſpect, and are never injured by Cold.

HEPATORIUM. *Vide* Eupatorium.

HEPTAPHYLLUM. *Vide* Pentaphyllum.

HERBA GERARDI. *Vide* Angelica ſylveſtris minor.

HERBALIST, HERBARIST, a Perſon who is ſkill'd in diſtinguiſhing the Kinds, Natures, or Virtues of *Herbs* or *Plants*.

HERBA PARIS; Herb-Paris, True-love, *or* One-berry.

The *Characters* are;

The Cup of the Flower conſiſts of four Leaves, which expand in form of a Croſs: The Flower alſo hath four Leaves, which expand in the ſame manner, and is generally furniſh'd with four Stamina: The Pointal of the Flower becomes a ſoft globular Fruit, which is divided into four Cells, and are fill'd with oblong Seeds.

We have but one *Species* of this Plant in *England*, which is,

HERBA PARIS. *J. B.* *Solanum quadrifolium, bacciferum. C. B.* Herb True-love, *or* One-berry.

This Plant is found wild in ſhady Woods in divers Parts of *England*, and is rarely cultivated in Gardens: Thoſe who have a mind to propagate it, ſhould ſearch it out in the natural Places of its Growth in *April*, when it firſt appears aboveground, and take up the Roots with a Clod of the natural Earth to them, and tranſplant them into a ſhady Part of the Garden, where, if they are not diſturb'd, they will live and flower; but they are not very apt to increaſe when cultivated. There is no great Beauty in this Plant; but thoſe who delight in Variety may give it Place in a Wilderneſs, where few other Things will thrive.

HERBIFEROUS, ſignifies bearing or bringing forth *Herbs*.

HERBIVOROUS, *i. e.* devouring or feeding on *Herbs* or *Graſs*.

To HERBORIZE; to go abroad in the Fields in queſt of different or new *Herbs* or *Plants*.

HERBOSE, *graſſy*, or full of *Graſs* or *Herbs*.

HERBOSITY, *Graſſineſs*, or Abundance of *Graſs* or *Herbs*.

HERBULENT, *graſſy*, full of *Graſs* or *Herbs*.

HERMANNIA. *Tournefort* gives the Name *Hermannia* to this Plant, in Honour of the immortal Memory of the celebrated *Hermannus*. It is called *Ketmia Africana* in the *Amſterdam* Garden: but *Ketmia* has a Calyx like that of the *Mallow*, and this a bladdery, ſquamoſe Calyx, by which it is eaſily diſtinguiſhed.

The *Characters* are;

The Cup of the Flower conſiſts of one Leaf, which reſembles a Bladder, and is cut into five Segments: The Flower conſiſts of five Leaves, the lowermoſt of which are narrow, but the upper ones are broad, and twiſted, having a pentangular Ovary in the Centre, which is ſurrounded by five Stamina, and is afterwards turn'd to a five-corner'd long Tube.

The *Species* are;

1. HERMANNIA *fruteſcens, folio oblongo ſerrato latiori. Boerh. Ind.* Shrubby Hermannia, with a broader, oblong, ſerrated Leaf.

2. HERMANNIA *fruteſcens, folio groſſulariæ parvo hirſuto. Boerh. Ind.* Shrubby Hermannia, with a ſmall, hairy, Gooſeberry Leaf.

3. HERMANNIA *fruteſcens, folio Ibiſci hirſuto molli, caule piloſo. Boerh. Ind.* Shrubby Hermannia, with a ſoft, hairy, Marſhmallow Leaf, and a woolly Stalk.

4. HERMANNIA *fruteſcens, folio oblongo ſerrato. Tourn.* Shrubby Hermannia, with an oblong, ſerrated Leaf.

5. HERMANNIA *fruteſcens, folio oblongo molli cordato hirſuto. Boerh. Ind.* Shrubby Hermannia, with a ſoft oblong hairy heart-ſhaped Leaf.

6. HERMANNIA *fruteſcens, folio multifido tenui, caule rubro. Boerh. Ind. alt.* Shrubby Hermania, with a narrow multifid Leaf, and a red Stalk.

7. HERMANNIA *fruteſcens, folio lavendulæ latiori & obtuſo, flore parvo aureo. Boerh. Ind. alt.* Shrubby Hermannia, with a broad blunt lavender Leaf, and a ſmall golden Flower.

The firſt four Plants are all propagated by planting Cuttings of them during any of the Summer Months, in a Bed of light freſh Earth, obſerving to water and ſhade them until they are well rooted, which will be in about ſix Weeks after planting; then you ſhould take them up, preſerving a Ball of Earth to their Roots, and plant them into Pots fill'd with light freſh Earth, placing them in a ſhady Situation until they have taken freſh Root; after which they may be expoſed to the open Air, with *Myrtles*, *Geraniums*, &c. until the Middle or latter End of *October*, when they muſt be removed into the Green-houſe; obſerving to place them in the cooleſt Part of the Houſe, and where they may have as much freſh Air as poſſible; for if they are too much drawn in the Houſe, they will appear very faint and ſickly, and ſeldom produce many Flowers; whereas, when they are only preſerv'd from the Froſt, and have a great Share of free Air, they will appear ſtrong and healthy, and produce large Quantities of Flowers in *April* and *May*, during which Seaſon they make a very handſome Shew in the Green-houſe: They muſt alſo be frequently watered, and will require to be new potted at leaſt twice every Year, *i. e.* in *May* and *September*, otherwiſe their Roots will be ſo matted, as to prevent their Growth.

Theſe Plants rarely produce good Seeds with us: but when they are obtain'd from Abroad, they muſt be ſown upon a moderate Hot-bed; and when the Plants come up, they muſt be tranſplanted into ſmall Pots, and plunged into another very moderate Hot-bed, in order to promote their rooting; after which they muſt be harden'd by degrees, to endure the open Air in Summer, and may then be treated as the old Plants.

The three laſt Sorts of Hermannia are Natives of the *Cape of Good Hope*, from whence they have been brought into the *European* Gardens. They may be propagated by Cuttings, which ſhould be planted in *June*, on a Bed of light Earth, being careful to ſhade them from the Sun until they have taken Root, as alſo to refreſh them with Water. When the Cuttings have taken Root, they may be expoſed to the open Air; but it will be proper to let them remain in the Bed until the Middle or latter End of *Auguſt*, when they ſhould be carefully taken up, and each planted in a ſeparate ſmall Pot, and placed in the Shade until they have taken new Root; after which time they may be expoſed with other hardy exotic Plants, in a ſheltered Situation, till *October*; when they muſt be removed into the Green-houſe, and placed where they may enjoy a large Share of Air in mild Weather; but muſt be protected from Froſt, and treated as hath been above directed.

HERMODACTYLUS, the Hermodactyl, commonly called *Snake's-head Iris*.

The *Characters* are;

It hath a lily-ſhaped Flower, conſiſting of one Leaf, and ſhaped exactly like an Iris; but has a tuberoſe Root, divided into two or three Dugs, like oblong Bulbs.

We have but one *Species* of this Plant, which is;

HERMODACTYLUS *folio quadrangulo. C. B. P.* Snake's-head Iris, *vulgo*. This is alſo called, *Iris tuberoſa Belgarum* *i. e.* The tuberoſe Iris of the *Dutch*.

This Plant is eaſily propagated by its Tubers, which ſhould be taken off ſoon after the green Leaves decay, which is the proper Seaſon for tranſplanting of the Roots; but they ſhould not be kept long out of the Ground, leſt they ſhrink; which will cauſe them to rot when they are planted. They ſhould have a loamy Soil, not too ſtrong, and muſt be planted to an *Eaſt* Aſpect, where they will flower very well. Theſe Roots ſhould not be removed oftener than once in three Years, if you deſign to increaſe them; but then they ſhould be planted at a farther Diſtance from each other than if they were to remain but one Year, and the Beds ſhould be kept clear from Weeds, and at *Michaelmas* there ſhould be ſome fine Earth laid over the Beds, which will greatly ſtrengthen their Roots. The Diſtance which theſe Plants ſhould be allowed is ſix Inches ſquare; and they ſhould be placed four Inches deep in the Ground. Theſe produce their Flowers in *May*, and their Seeds are ripe in *Auguſt*; but as they multiply pretty faſt by their Roots, ſo few People are at the Trouble to raiſe them from Seeds; but thoſe who have an Inclination ſo to do, muſt treat them in the Manner directed for the *bulbous Iris's*.

This Plant has by ſome Botanick Writers been ſuppoſed the true *Hermodactyl*; but what has been long uſed in *Europe* for that, is a true *Colchicum*. *Vide* Colchicum.

HERNANDIA, Jack in a Box, *vulgo*.

The *Characters* are;

It hath a ſhort, multifid, ſpreading bell-ſhaped Flower, or a roſaceous Flower, conſiſting of ſeveral Petals, which are placed in a circular Order; theſe are ſome of them barren, and others are fertile: The Cup of the Flower afterward becomes an almoſt ſpherical Fruit, which is ſwelled and perforated, containing a ſtriated, roundiſh Nut.

We have but one *Species* of this Plant, which is,

Hernandia *amplo hederæ folio umbilicato. Plum.* Hernandia, with a large umbilicated ivy Leaf, commonly called in the *Weſt-Indies*, *Jack in a Box*.

This Plant is very common in *Jamaica, Barbadoes, St. Chriſtophers*, and many other Places in the *Weſt-Indies*; where it is known by the Name of *Jack in a Box*. The Fruit of this Plant, when ripe, is perforated; and the Nut in the Inſide becoming hard, the Wind blowing through the Fruit makes a whiſtling Noiſe, which may be heard at a Diſtance; from whence, I ſuppoſe, the Inhabitants gave it this Name. It grows in the Gullies, where there are Rills of Water.

In *Europe* this Plant is preſerved in curious Gardens, with other tender exotic Plants. It is propagated by ſowing of the Seeds on a Hot-bed in the Spring; and when the Plants have ariſen two Inches high, they ſhould be tranſplanted each into a ſeparate Pot, filled with freſh rich Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken Root; after which Time they muſt have Air admitted to them (by raiſing of the Glaſſes) in proportion to the Warmth of the Air, or the Heat of the Bed in which they are placed; and they muſt be frequently watered, otherwiſe they will not thrive. As the Plants advance, ſo they ſhould be removed into larger Pots, which ſhould be filled with rich Earth; but in doing of this, you ſhould be very careful not to break the Roots, as alſo to preſerve a good Ball of Earth to them; they muſt alſo be well watered, and if their Leaves ſhould hang after being removed, the Plants muſt be ſcreened from the Sun until they have taken new Root; the beſt Time to ſhift theſe Plants is in *July*, that they may be well rooted before the Cold approaches; and the Plants muſt be conſtantly kept in the Bark-ſtove: In Winter they ſhould have a moderate Share of Heat, and in Summer they muſt have a large Share of Air in hot Weather. With this Management the Plants will grow to the Height of ſixteen Feet, or more; and the Leaves, being very large, will make a beautiful Appearance in the Stove. It hath not as yet flowered in *England*, tho' we may expect ſome of the large Plants to flower in a ſhort Time.

HERNIARIA, [of *Hernia*, Lat. *a Rupture*] Rupturewort.

The *Characters* are;

The Calyx is quadrifid, or, for the moſt part, quinquifid, and expanded in form of a Star, having five Stamina in the Center: The Fruit (which grows on the Bottom of the Flower) becomes a membranaceous, furrow'd, round Capſule, which is divided into eight Cells, each of which contains one ſmall pointed Seed.

The *Species* are;

1. Herniaria *glabra. J. B.* Smooth Rupturewort.
2. Herniaria *hirſuta. J. B.* Rough *or* hairy Rupturewort.
3. Herniaria *alſines folio. Tourn.* Rupturewort, with a Chickweed Leaf.
4. Herniaria *fruticoſa, viticulis lignoſis. C. B.* Shrubby Rupturewort, with woody Branches.

Theſe Plants are ſeldom cultivated but in botanick Gardens, for the ſake of Variety: The three firſt are, for the moſt part, annual Plants, ſeldom continuing longer than one Year, and muſt be permitted to ſhed their Seeds, whereby they are better preſerv'd than if ſown with Art. The fourth Sort is an abiding Plant, which may be propagated by Cuttings: but as they are Plants of no Beauty, ſo they are not worth cultivating.

The firſt Sort is what ſhould be uſed in the Shops, but is rarely ſeen in *London*; the Herb-women commonly bringing the *Parſley Break-ſtone* to the Markets, which is ſold inſtead of this Plant.

HESPERIS: [Some derive the Name of this Plant from *Heſperia, Italy*, from whence the People were anciently call'd *Heſperides*; but it is pretty plain that the Name was taken from Ἑσπερος, becauſe moſt commonly they ſmell moſt in an Evening; either of theſe may be admitted. It is call'd *Viola Matronalis*, becauſe it reſembles the *Violet*, and was at firſt cultivated by Women] Dame's Violet, *or* Queen's Gilliflower.

The *Characters* are;

The Flower conſiſts, for the moſt part, of four Leaves, which expand in form of a Croſs; out of the Flower-cup ariſes the Pointal, which becomes a long, taper, cylindrical Pod, which is divided into two Cells by an intermediate Partition, to which the imbricated Valves do adhere on both Sides, and are furniſhed with oblong, cylindrical, or globular Seeds.

The *Species* are;

1. Hesperis *hortenſis, flore purpureo. C. B. P.* Garden Dame's Violet, with a purple Flower.
2. Hesperis *hortenſis, flore candido. C. B. P.* Garden Dame's Violet, with a white Flower.
3. Hesperis *ſylveſtris inodora. C. B. P.* Unſavoury wild Dame's Violet.
4. Hesperis *hortenſis, flore variegato. Jeſſieu.* Garden Dame's Violet, with a variegated Flower.
5. Hesperis *hortenſis, flore purpureo pleno. H. R. Par.* Garden Dame's Violet, with a double purple Flower, *commonly called* Double Purple Rocket.
6. Hesperis *hortenſis, flore albo pleno. H. R. P.* Garden Dame's Violet, with a double white Flower, or double white Rocket.
7. Hesperis *hortenſis, flore vario pleno. H. R. Par.* Garden Dame's Violet, with a variable Flower.
8. Hesperis *maritima ſupina exigua. Tourn.* Low Maritime Dame's Violet.
9. Hesperis *montana pallida odoratiſſima. C. B. P.* Pale Mountain Dame's Violet, with a very ſweet Smell.

There are many other Varieties of this Plant, which are preſerved in botanick Gardens, to add to their Variety; but theſe here mentioned are the moſt beautiful Kinds, and beſt worth propagating in the Flower-Garden.

The ſeven firſt mention'd Sorts are abiding Plants, and may be propagated by parting of their Roots in *Auguſt*, eſpecially thoſe with double Flowers, which never produce Seeds; but the ſingle Kinds are better propagated by ſowing their Seeds in *March*, which will produce ſtronger Plants than thoſe obtained from Off-ſets. The Heads which are divided, ſhould be well furniſhed with Roots, otherwiſe they are very ſubject to miſcarry: Nor ſhould the old Roots be ſeparated into very ſmall Heads, which would occaſion their flowering weak the ſucceeding Seaſon. The Soil in which theſe Plants ſhould be planted, ought to be freſh, and inclining to a ſandy Loam; but ſhould not be mixed with Dung, which often cauſes the Roots to rot: but if you bury ſome rotten Wood-pile Earth, or very rotten Tanners-bark, juſt deep enough for their Fibres to reach it, the Plants will thrive exceedingly, and produce great Quantities of very large fair Flowers, as I have ſeveral Times experienc'd: But if this ſhould be ſo ſhallow as to touch the main Roots, 'tis ten to one if they don't rot away; which is very often the Caſe with theſe Flowers, when they are planted in a rich dung'd Soil. The double white *Rocket* is by far the moſt beautiful Plant of all the Kinds, the Flowers of which are as large and double as the faireſt double *Stock-Gilliflower:* It was formerly planted in great Plenty in the Gardens near *London*, to ſupply the Markets with Flowers for Baſons; for which Purpoſe there is not any Plant better adapted, and will continue in Beauty for a long Time: But of late Years theſe Plants have not ſucceeded ſo well as formerly, which may be owing to the dunging of the Soil; for it is obſervable, that in freſh Ground, which has not been till'd, theſe Plants do ſucceed beſt. The ſingle Kinds have very little Beauty in them, when compar'd with the double, and are therefore ſeldom cultivated in Gardens: But as they are much hardier than the double, and will thrive in a ſhady Border, ſo they may be admitted for Variety. Theſe all produce their Flowers in *May*, and the ſingle Kinds do perfect their Seeds in *Auguſt*; which, if ſuffer'd to ſhed upon the Ground, will come up very well, and ſave the Trouble of ſowing them.

The eighth Sort is a very low Plant, which may be ſown for Edgings, or in Patches on the Borders of the Pleaſure-Garden, as the *Dwarf-Lychnis*, *Venus Looking-glaſs*, and other low annual Plants are uſually cultivated, to imbelliſh the Borders in Autumn, after moſt other Flowers are paſt. The Seed may be ſown in *April* or *May*, to flower late. But the Method to have this Plant in the greateſt Perfection, is to ſow the Seeds in ſmall Patches in the Borders under warm Walls in *Auguſt*, which will come up ſoon after, and the Plants will get Strength enough to endure the Cold; and in the Spring following theſe will produce much larger Flowers than thoſe which come up in the Spring.

The ninth Sort is a biennial Plant, ſeldom continuing longer than two Years: This muſt be propagated by ſowing the Seeds in the Manner directed for the firſt Sorts, and the ſecond Year the Plants will flower; which if you intend to preſerve, you muſt cut off moſt of the Flower-ſtems, before the Flowers decay; which will occaſion the Roots to put out new Heads, if they are ſound, whereby they may be often continued three or four Years.

HIERACIUM, of Ἱέραξ, Gr. a *Hawk*; ſo call'd, becauſe Hawks, as well as Eagles, have a ſtrong and quick Sight; and it is reported, that if, by reaſon of the Heat of the Air, a Film grows over the Eyes of this Bird, then the Parent drops a Drop of the Juice of it in its Eye; and that, in like manner, it is good to clear the human Sight] Hawkweed.

The *Characters* are;

The Stalks are branched and ſlender: The Leaves are produced alternately: The Cup of the Flower is ſhort, firm and expanded: The Flower conſiſts of many Leaves, which are placed in an orbicular Order, and open in form of a Marygold: *The Seeds are ſlender and angular, or furrow'd: To which may be added, the whole Plant hath a milky Juice.*

The *Species* are;

1. HIERACIUM *murorum, folio pilociſſimo. C. B. P.* Golden Hawkweed, with hairy Leaves.

2. HIERACIUM *Pyrenaicum, folio cerinthes, latifolium. Schol. Bot. Pyrenian* Hawkweed, with a broad Honeywort Leaf.

3. HIERACIUM *folio dentis leonis, flore ſuave-rubente. C. B. P.* Red-flower'd Hawkweed, with Dandelyon Leaves.

4. HIERACIUM *lanatum, ſonchi vel erigerontis facie. H. L.* Downy Hawkweed, with the Face of Sowthiſtle, *or* Groundſel.

5. HIERACIUM *medio nigrum Bœoticum majus. Par. Bat.* Greater *Spaniſh* Hawkweed, with yellow Flowers, having black Bottoms.

6. HIERACIUM *medio nigrum Bœoticum majus, flore ſulphureo.* Greater *Spaniſh* Hawkweed, with Brimſtone colour'd Flowers, having black Bottoms.

7. HIERACIUM *barbatum medio nigrum minus. H. L.* Leſſer Hawkweed, with yellow Flowers, having black Bottoms.

8. HIERACIUM *latifolium piloſum coccineum umbellatum Indicum. H. L.* Broad-leav'd *Indian* Hawkweed, with ſcarlet Flowers growing in an Umbel.

9. HIERACIUM *longius radicatum. Ger. Emac.* Long-rooted Hawkweed.

10. HIERACIUM *minus, præmorſa radice. Park.* Hawkweed with bitten Roots, or yellow Devils-bit.

11. HIERACIUM *primum latifolium. Cluſ.* Broad-leav'd *Hungarian* Hawkweed.

12. HIERACIUM *fruticoſum latifolium hirſutum. C. B.* Buſhy Hawkweed, with broad rough Leaves.

13. HIERACIUM *fruticoſum latifolium glabrum. Park. Theat.* Smoother broad-leav'd buſhy Hawkweed.

14. HIERACIUM *fruticoſum anguſtifolium majus. C. B.* Narrow-leav'd buſhy Hawkweed.

15. HIERACIUM *pulmonaria dictum, anguſtifolium. Raii Syn.* Narrow-leav'd Hawkweed, commonly called Golden Lungwort.

16. HIERACIUM *macrocaulon hirſutum, folio rotundiore. D. Lawſon.* Round-leav'd rough Hawkweed, with a tall Stalk.

17. HIERACIUM λεπτοκαῦλον *hirſutum, folio longiore. D. Lawſon.* Slender-ſtalk'd rough Hawkweed, with a longer Leaf.

18. HIERACIUM *murorum laciniatum minus piloſum. C. B.* Golden Lungwort, with more jagged Leaves.

19. HIERACIUM *murorum folio longiore diſſecto, maculis lividis aſperſo. Vaill. Mem. Acad. Scien.* Long cut-leav'd Golden Lungwort, with ſpotted Leaves.

20. HIERACIUM *caſtorei odore, Monſpelienſium. Raii Syn.* Hawkweed of *Montpelier*, ſmelling like Caſtor.

21. HIERACIUM *luteum glabrum, ſive minus hirſutum. J.B.* Smoother yellow Hawkweed.

22. HIERACIUM *montanum, cichorei folio, noſtras. Raii Syn.* Succory-leav'd mountain Hawkweed.

23. HIERACIUM *maximum, chondrillæ folio, aſperum. C. B.* The greateſt rough ſuccory-leav'd Hawkweed.

24. HIERACIUM *echioides, capitulis cardui Benedicti. C. B.* Hawkweed like Vipers Bugloſs, with Heads like the Bleſſed Thiſtle, commonly called Ox Tongue.

25. HIERACIUM *pulmonaria dictum latifolium humilius, ramulis expanſis. Act. Phil. N.* 417. Dwarf branching Hawkweed, with broad Leaves.

26. HIERACIUM *Sabaudum altiſſimum, foliis latis brevibus crebrius naſcentibus. Mor. Hiſt.* Talleſt *Savoy* Hawkweed, with broad Leaves.

27. HIERACIUM *fruticoſum, anguſtiſſimo incano folio. H. L.* Buſhy Hawkweed, with very narrow hoary Leaves.

28. HIERACIUM *Pyrenaicum rotundifolium amplexicaule. Inſt. R. H.* Round-leav'd *Pyrenean* Hawkweed, whoſe Leaves embrace the Stalks.

29. HIERACIUM *murorum, foliis maculis & lituris atrorubentibus, pulchre variegatis. Vaill. Mem. Acad. Scien.* Hawkweed whoſe Leaves are beautifully marked with dark red Spots.

30. HIERACIUM *fruticoſum latifolium, foliis dentatis, glabrum. C. B.* Broad-leav'd buſhy Hawkweed, with ſmooth indented Leaves.

31. HIERACIUM *magnum Dalechampii, folio minus laciniato.* Greater Hawkweed of *Dalechamp*, with leſs cut Leaves.

32. HIERACIUM *magnum Dalechampii, folio majus laciniato.* Greater Hawkweed of *Dalechamp*, with more cut Leaves.

The firſt, ſecond, and eighth Sorts are abiding Plants, and may be propagated by parting their Roots either in Spring or Autumn, and ſhould be planted in a freſh, light Soil, and an open Situation, where they will greatly increaſe, eſpecially the eighth Sort, which is very ſubject to creep under Ground, and ſend forth Abundance of Heads, whereby the Seaſon of Flowering is continued thro' moſt Part of the Summer; for the new Off-ſets commonly produce Flowers ſoon after they come up. Theſe are alſo propagated by Seeds, which ſhould be ſown either in the Autumn, ſoon after they are ripe, or very early in the Spring; for if they are ſown very late, the Plants ſeldom come up until the Autumn following, whereby a whole Seaſon is loſt; but as they increaſe ſo faſt by Off-ſets, it is hardly worth while to ſow their Seeds.

The third, fourth, fifth, ſixth, and ſeventh Sorts are annual Plants, which for the Variety of their Flowers deſerve a Place in a Garden; theſe Plants are much ſtronger, and produce a greater Quantity of Flowers, when they are rais'd in the Autumn, than thoſe which are ſown in the Spring, and they are ſo hardy as to endure the ſevereſt Cold of our Climate in the open Air, provided they are planted or ſown upon a dry Soil, for too much Wet is apt to rot them: The beſt Seaſon for ſowing the Seeds is in *Auguſt*; and towards the latter End of *September* the Plants will be ſtrong enough to tranſplant, which ſhould be into the Borders where they are to remain for Flowering; theſe will produce their Flowers in *May*, and their Seeds will be ripe in *July*, which, if ſuffered to ſhed upon the Ground, will grow, and ſave the Trouble of ſowing them.

The Sorts from the ninth to the twenty-fifth are Natives of *England*; ſome of them grow in ſhady Woods, and others upon dry Banks, and on old Walls in divers Places. The ninth, tenth, eleventh, twelfth, thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth, nineteenth, and the twenty-fifth Sorts, are abiding Plants; which may be propagated either by parting of their Roots, or from Seed: If they are propagated by parting of their Roots, it muſt be done about *Michaelmas*, that the Plants may be rooted before the Froſt comes on; for if this Work be deferr'd till the Spring, the Plants will not have taken good Root before the Summer comes on, which will cauſe them to flower weak. Theſe Roots ſhould not be removed oftner than every third Year, becauſe when the Plants have a Number of Heads, they will ſend forth ſo many Stalks for flowering; whereby they will make a more beautiful Appearance.

The five next mentioned Sorts are not Natives of this Country, but they are equally hardy with thoſe before-mentioned, and may be propagated in the ſame Manner. Theſe Plants are ſeldom introduced into Gardens, becauſe they are common in *England*; but they may be planted in Wilderneſs-quarters, and under the Shade of Trees, where they will thrive very well, and afford an agreeable Variety where few other Plants will live; and as they require no farther Care after planting, ſo the Trouble will be little in procuring of the Plants; and when they are once fixed in the Ground, they will abide many Years without any farther Culture. If the Seeds of theſe Plants are permitted to ſcatter, they will produce a plentiful Supply of young Plants. Or when a Perſon is deſirous to propagate them by Seeds, it ſhould be ſown in Autumn, ſoon after it is ripe; for if it is kept till the Spring, it doth not ſucceed ſo well.

The twenty-firſt, twenty-ſecond, twenty-third, and twenty-fourth Sorts are alſo Natives of *England*; but are not abiding Plants, for they ſeldom continue longer than two Years. The Seeds of theſe Plants may be ſown on an open Bed or Border of freſh undunged Earth; and when the Plants come up, they ſhould be cleared from Weeds, and thinned where they are too thick, which is all the Culture they require. If theſe Seeds are ſown in Autumn, ſoon after they are ripe, the Plants will ſoon appear, and get ſtrength before Winter, ſo will flower the following Summer; but if they are not ſown till the Spring, the Plants ſeldom flower until the Year after.

The thirty-firſt and thirty-ſecond Sorts grow wild in the South of *France*, and in *Italy*; yet are hardy enough to endure the Cold of our ordinary Winters very well, in the open Air. The Seeds of theſe Plants ſhould be ſown in the Spring, on a Bed of freſh undunged Earth, where they are deſigned to remain (becauſe they ſeldom ſucceed when they are tranſplanted). When the Plants are come up they ſhould be cleared from Weeds, and where they are too cloſe, they ſhould be thinned, leaving them about eight or ten Inches aſunder. Some of theſe Plants will flower the firſt Year they are ſown, but theſe will not produce good Seeds; but thoſe which live over the Winter, will flower early the following Summer, and, if the Seaſon proves favourable, will produce good Seeds in *Auguſt*. Theſe Plants ſeldom continue longer than two Years; ſo that Seeds ſhould be annually ſown, in order to preſerve their Kinds; for as they continue in Flower the greateſt Part of the Summer, they merit a Place in every good Garden.

HILLS have many Uſes, of which I ſhall only mention two or three.

1ſt, They ſerve as Skreens to keep off the cold and nipping Blaſts of the northern and eaſtern Winds.

2dly, The long Ridges and Chains of lofty Mountains being generally found to run from Eaſt to Weſt, ſerve to ſtop the Evagation of thoſe Vapours towards the Poles, without which they would all run from the hot Countries, and leave them deſtitute of Rain.

3dly, They condenſe thoſe Vapours, like Alembick Heads, into Clouds, and ſo by a kind of external Diſtillation, give Origin to Springs and Rivers; and by amaſſing, cooling and conſtipating them, turn them into Rain, and by that Means render the fervid Regions of the Torrid Zone habitable.

4thly, They ſerve for the Production of a great Number of Vegetables and Minerals, which are not found in other Places.

It has been found by Experiment and Calculation, that *Hills*, tho' they meaſure twice as much Ground as the Plain Ground they ſtand upon, yet the Produce of the one can be no more than the other, and therefore in purchaſing Land, the *Hills* ought not to be bought for more than their ſuperficial Meaſure, *i. e.* to pay no more for two Acres upon the Side of an Hill, than for one upon the Plain, if the Soil be equally rich.

It is true that thoſe Lands that are Hilly and Mountainous, are very different as to their valuable Contents, from what are found in flat and plain Ground, whether be planted, ſown or built upon; as for Example:

Suppoſe an *Hill* contains four equal Sides, which meet in a Point at the Top, yet the Contents of theſe four Sides can produce no more Grain, or bear no more Trees, than the plain Ground on which the *Hill* ſtands, or than the Baſe of it; and yet by the Meaſure of the Sides, there may be double the Number of Acres, Rods, and Poles, which they meaſure on the Baſe or Ground-Plot.

For as long as all Plants preſerve their upright Method of growing, hilly Ground can bear no more Plants in Number than the Plain at the Baſe.

Again, as to Buildings on an *Hill*, the true Sides of an *Hill* will bear no more than the ſame Number of Houſes that can ſtand in the Line at the Baſe.

And as to *Rails*, or *Park-pailing* over an *Hill*, tho' the Meaſure be near double over the *Hill* to the Line at the Bottom, yet both may be incloſed by the ſame Number of Pales of the ſame Breadth.

HIPPOCASTANUM [of Ἵππος, Gr. *a Horſe*, and *Caſtanea*, Lat. *a Cheſnut*] Horſe-Cheſnut.

The *Characters* are;

It hath digitated or finger'd Leaves; the Flowers, which conſiſt of five Leaves, are of an anomalous Figure, opening, as it were, with two Lips; there are Male and Female upon the ſame Spike, which when fully blown, make a ſpecious Shew, being always produced at the Extremity of the Branches; the Female Flowers are ſucceeded by Nuts which grow in green prickly Huſks.

The *Species* are;

1. HIPPOCASTANUM *vulgare. Tourn.* Common Horſe-Cheſnut.

2. HIPPOCASTANUM *vulgare, foliis ex luteo variegatis.* The yellow blotch'd Horſe Cheſnut.

3. HIPPOCASTANUM *vulgare, foliis ex albo variegatis.* The white blotch'd Horſe-Cheſnut.

The firſt of theſe Trees (of which there ſeem to be two or three Varieties differing in the Breadth of their Leaves, and the Colour of their Flowers, one of which hath its Flowers remarkably ſpotted with Red and Yellow, ſo as to be ſeen at a great Diſtance, and is ſomewhat later in flowering) is very common in *England*, having been greatly cultivated for planting Avenues and ſhady Walks near Habitations, where, in the Spring of the Year, (which is their Seaſon for flowering) they make a moſt beautiful Shew, and their Leaves being very large, afford an agreeable Shade in the Heat of Summer; but if the Number of theſe Trees be too great, or too near the Habitation, they cauſe the circumambient Air to be moiſt and unhealthy, by the large Quantities of Moiſture which they perſpire thro' their Leaves, ſo that they ſhould always be placed at ſuch a Diſtance, as to admit of a free Current of Air to paſs between them and the Building, that the rancid Air may be carried off thereby.

This Tree is propagated by planting the Nuts early in the Spring, after the Manner as was directed for the common Cheſnut (to which I refer the Reader, to avoid Repetition) the Spring following the Plants may be tranſplanted into a Nurſery, in Rows at three Feet diſtance, and eighteen Inches aſunder in the Rows, where they may continue three Years; after which Time they may be tranſplanted for Avenues, &c. where they are to remain: The beſt Seaſon for tranſplanting theſe Trees is at the latter End of *February*, or the Beginning of *March*; (tho' indeed, they may be tranſplanted in Autumn, or during any of the Winter Months, when other deciduous Trees are removed) but the other is the ſureſt Seaſon, eſpecially for moiſt Soils.

In tranſplanting of theſe Trees, we ſhould never ſhorten any of their Branches; but only cut off intirely all ſuch as are ill placed, or grow irregular; for theſe Trees have always a large turgid Bud placed at the Extremity of their Branches, in which is incloſed the Shoot for the ſucceeding Spring, which Bud is of great Service in attracting the Nouriſhment, and promoting the future Growth of the Tree; and it is often obſervable, where their Branches are ſhortned, that there is produced a glutinous Subſtance, almoſt of the Conſiſtence of Turpentine, which often occaſions the Decay of thoſe particular Branches, and ſometimes of the whole Tree.

Theſe Trees have ſomething very ſingular in their Growth, *i. e.* that their whole Year's Shoot is commonly performed in three Weeks Time, after which it does no more than increaſe in Bulk, and become more firm and ſubſtantial; and all the latter Part of the Summer is occupied in forming and ſtrengthening the Buds for the next Year's Shoots. There is a great Regularity in the natural Growth of theſe Trees, their Underbranches being always greatly extended, and the ſucceeding ones decreaſing gradually to the Top, do form a natural obtuſe Pyramid, which Regularity is by many People greatly diſliked, as appearing too much like thoſe artificial Pyramids, which were formerly ſo much eſteem'd and cultivated on ever-green Trees; but are now very juſtly deſpiſed by all curious Perſons: Tho' it muſt be allowed, where theſe Trees are rightly diſpoſed in forming of Clumps, &c. their conical Figure has a very good Effect, by rendering ſuch Plantations very agreeable to the Eye at ſome Diſtance, eſpecially when the under Parts of the Trees are hid from Sight, by other Trees which ſurround them.

Theſe Trees were originally brought from *Conſtantinople* into *Europe*; but altho' they are Natives of ſo warm a Country, yet they are now ſo enur'd to the Cold, as to defy the ſevereſt of our Winters, and do grow to be very large Trees, and produce great Quantities of Nuts annually, from which they may be multiplied at Pleaſure. The Fruit of this Tree is very bitter, and of no Uſe amongſt us at preſent; but in *Turky* they give them to Horſes, in their Provender, that are troubled with Coughs, or are ſhort-winded, in both which Diſtempers they are ſuppoſed to be very good.

HIPPOLAPATHUM. *Vide* Lapathum.

HIPPOSELINUM. *Vide* Smyrneum.

HIRUNDARIA. *Vide* Aſclepias.

HOLLOW ROOT. *Vide* Fumaria.

HOLLY-HOCKS. *Vide* Malva roſea.

HOLLY. *Vide* Aquifolium.

HOMOGENEAL or HOMOGENEOUS *Plants*, are ſuch Plants as are of the ſame Kind or Nature with others.

HONEY-SUCKLE. *Vide* Caprifolium.

HOPS. *Vide* Lupulus.

HORDEUM; Barley.

The *Characters* are;

It hath a thick Spike; the Calyx, Huſk, Awn, and Flower, are like thoſe of Wheat or Rye, but the Awns are rough; the Seed is ſwelling in the middle, and for the moſt Part ends in a ſharp Point, to which the Huſks are cloſely united.

The *Species* are;

1. Hordeum *diſtichum. Ger.* Common long-ear'd Barley.
2. Hordeum *polyſtichum, vel hybernum. Park.* Winter or Square Barley, or Bear Barley; by ſome call'd Big.
3. Hordeum *diſtichum, ſpica breviore & latiori, granis confertis. Raii.* Sprat Barley or Battle-door Barley.

The firſt and third Sorts are commonly cultivated in *England*; but the ſecond is rarely to be ſeen near *London*, tho' I think it much preferable to the other two, as producing a larger Seed, and very full thick Spike.

But, beſide theſe three, there are two other Sorts, which are cultivated in *England*; which are, the *Rath-ripe*, and *Naked Barley*; this laſt is ſometimes called *French Barley*: This makes tolerable good Bread, very good Malt, and yields a large Increaſe.

All theſe Sorts of *Barley* are ſown in the Spring of the Year, in a dry Time; in ſome very dry light Land, the Barley is ſown early in *March*, but in ſtrong clayey Soils it is not ſown till *April*, and ſometimes not until the beginning of *May*; but when it is ſown ſo late, if the Seaſon doth not prove very favourable, it is very late in Autumn before it is fit to mow, unleſs it be the Rath-ripe ſort, which is often ripe in nine Weeks from the Time of ſowing.

The *Square Barley* or *Big* is chiefly cultivated in the North of *England*, and in *Scotland*, and is hardier than the other Sorts; but this is ſeldom ſown in the South of *England*, tho' it might be cultivated to good Purpoſe on ſome ſtrong cold clayey Lands, where the other Kinds do not thrive ſo well.

Some People ſow Barley upon Land where Wheat grew the former Year; but when this is practiſed, the Ground ſhould be ploughed the Beginning of *October* in a dry Time, laying it in ſmall Ridges, that the Froſt may mellow it the better, and this will improve the Land greatly: Then in *March* the Ground is ploughed again, and laid even where it is not very wet; but in ſtrong wet Lands the Ground ſhould be laid round, and the Furrows made deep to receive the Wet. When this is finiſhed, the Seed ſhould be ſown with a broad Caſt at two Sowings; the firſt being harrowed in once, the ſecond ſhould be harrowed until the Seed is buried: The common Allowance of Seed is four Buſhels to an Acre.

When the Barley is ſown, the Ground ſhould be rolled after the firſt Shower of Rain, to break the Clods, and lay the Earth ſmooth; which will render it better to mow, and alſo cauſe the Earth to lie cloſer to the Roots of the Corn, which will be of great Service to it in dry Weather.

Where Barley is ſown upon new broken up Land, the uſual Method is, to plough up the Land in *March*, and let it lie fallow until *June*; at which time it is ploughed again, and ſown with *Turnips*, which are eaten by Sheep in Winter, by whoſe Dung the Land is greatly improved; and then in *March* following the Ground is ploughed again, and ſown with Barley as before.

There are many People who ſow *Clover* with their *Barley*, and ſome have ſown the *Lucern* with *Barley*, but neither of theſe Methods are to be commended; for where there is a good Crop of *Barley*, the *Clover* or *Lucern* muſt be ſo weak as not to pay for ſtanding; ſo that the better Way is to ſow the *Barley* alone without any other Crop among it, and then the Land will be at Liberty for any other Crop, when the Barley is taken off the Ground.

When the Barley is ripe, (which may be known by the Colour of the Ears and the Straw) it muſt be mown down; and where there are a great Number of Weeds among it, it muſt lie on the Swarth till the Weeds are decayed; but if there ſhould happen to fall Rain, the *Barley* muſt be ſhook and turned every Day, to prevent its ſprouting or growing muſty; and when it is well dried, it ſhould be made up in Cocks; for if it is houſed or mowed too green, it is very apt to burn; which will render it unfit for Malting, and worſe for moſt Purpoſes, than if it ſprouted in the Field. The uſual Produce is from two to three Quarters of *Barley* on an Acre.

HORIZONTAL SHELTERS, have by ſome Perſon been greatly recommended to preſerve Fruit-Trees from Blights; but with how little Reaſon, or upon what ſlight Experiments, every one who has ever made uſe of them, will eaſily judge; eſpecially thoſe which are contrived by placing Tiles in the Wall at certain Diſtances, nothing being more obvious than that Vegetables, when prevented from receiving the Benefit of Dews, Rains, &c. thoſe kindly Benefits o Heaven, do grow weak, languid, and at laſt intirely decay And ſince from vaſt Numbers of Experiments which have bee lately made, we find that Trees imbibe great Quantities o Nouriſhment through the Pores of their Leaves and Branche whereby they are rendred vigorous and healthy even in ſuc Seaſons, and upon ſuch Soils, where one would think it im poſſible they ſhould receive much Nouriſhment from the Earth ſo to deprive them of this Advantage, is no leſs than deſtroy ing them; though perhaps if the Trees are vigorous, it ma not be effected ſuddenly, but there will be very viſible Signs o Decay on them daily, and a few Years will put a Period t their Lives, as I have more than once obſerved, where ſuc Walls were built.

The only Sort of theſe Shelters which I have ever obſerv uſeful for Fruit-Trees, was made with two Leaves of ſ Deal, join'd over each other and painted; this being fix upon the Top of the Wall with Pullies, to draw up and do at pleaſure, formed a ſort of Penthouſe, which being let dow in great Rains, or cold Nights, during the Time that the Tre were in flower, or the Fruit was ſetting, proved ſerviceable but then theſe Shelters were removed away ſoon after the Fr was ſet, ſo that the Trees might enjoy all the Advantages Rain, Dew, &c. in the Summer; which is abſolutely nec ſary, if we would have healthy Trees, or good Fruit.

HORMINUM [is ſo call'd of ὁρμᾶν, *Gr.* to *ruſh*, or *carried with a Force*, becauſe by its Force it ſtimulates a violently increaſes the venereal Appetite] Clary.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe up Lip is ſhort and creſted, but the under one is divided into th Parts, the middle Diviſion is hollowed like a Spoon; out of Flower-cup ariſes the Pointal, fixed like a Nail to the hin Part of the Flower, and attended with four Embryo's which a terwards turn to ſo many roundiſh Seeds, incloſed in the Cup the Flower.

The *Species* are;

1. Horminum *ſylveſtre, lavendulæ flore. C. B. P.* Co mon Engliſh wild Clary, or *Oculus Chriſti.*
2. Horminum *coma purpureo-violacea. I. B.* Clary, w a purple-violet Top.
3. Horminum *ſylveſtre latifolium verticillatum. C. B.* Broad-leav'd wild Clary, with whorled Spikes.
4. Horminum *pratenſe, flore minimo. Schol. Bot.* M dow Clary, with a very ſmall Flower.
5. Horminum *ſpicatum, lavendulæ flore & odore. Rar. Pl.* Spiked Clary, with the Flower and Smell Lavender.

6. H

6. **Horminum** *napi folio. Morif. H. Bleſ.* Turnep-leav'd Clary.

7. **Horminum** *Orientale, betonicæ folio acutiſſimo, flore cæruleo. Tourn. Cor.* Eaſtern Clary, with a ſharp-pointed betony Leaf, and a blue Flower.

8. **Horminum** *Orientale, betonicæ folio acutiſſimo, flore albo. Tourn. Cor.* Eaſtern Clary, with a ſharp-pointed betony Leaf, and a white Flower.

9. **Horminum** *Orientale latifolium glutinoſum, flore partim albo, partim purpuraſcente. Tourn. Cor.* Eaſtern Clary, with broad glutinous Leaves, and a Flower partly white and partly purpliſh.

10. **Horminum** *Orientale latifolium glutinoſum, flore albo. Tourn. Cor.* Eaſtern Clary, with broad glutinous Leaves, and a white Flower.

11. **Horminum** *Orientale, betonicæ folio anguſtiore & inodoro. Tourn. Cor.* Eaſtern Clary, with a narrow betony Leaf, without Smell.

12. **Horminum** *Orientale, lamii folio. Tourn. Cor.* Eaſtern Clary, with a dead-nettle Leaf.

13. **Horminum** *Orientale, foliis ſclareæ, flore albo parvo. Tourn. Cor.* Eaſtern Clary, with the Leaves of *Sclarea*, and a ſmall white Flower.

14. **Horminum** *Orientale, foliis rugoſis & verrucoſis anguſtis, flore albo. Tourn. Cor.* Eaſtern Clary, with rough narrow-warted Leaves, and a white Flower.

15. **Horminum** *verbenæ laciniis, anguſtifolium. Triumph.* Clary with a narrow jagged vervain Leaf.

16. **Horminum** *Orientale annuum, ſativo ſimile, comâ carens, flore violaceo. Tourn. Cor.* Annual Eaſtern Clary, like the Garden Clary, wanting Tops, and a violet-coloured Flower.

The firſt of theſe Plants is found wild upon dry Banks, in diverſe Parts of *England*, and is ſeldom cultivated in Gardens; the Seeds of this Kind are by ſome People greatly eſteem'd for clearing the Eyes, of any thing that may have gotten into them, which is effected by the glutinous Quality of the Seed, which when put into the Eye, and moved about, will faſten any thing thereto which it meets with, and thereby it is taken out.

The ſecond Sort is a beautiful annual Plant and deſerves to have a Place in a good Garden, for the Oddneſs of its Spikes, which have fine purple-violet colour'd Tops: But the third Sort is not very beautiful, and is chiefly cultivated in Botanick Gardens, with many other Varieties of leſs Note.

Theſe may all be propagated by ſowing their Seeds in the Spring in an open Situation, and when the Plants are come up, they ſhould be either tranſplanted out to the Diſtance of a Foot ſquare, or hough'd out to the ſame Diſtance, obſerving to keep 'em clear from Weeds, which is all that is needful to be regarded in their Culture.

The firſt and third Sorts are abiding Plants, their Roots continuing ſeveral Years; but the ſecond Sort will decay ſoon after the Seeds are perfected. If the Seeds of this Kind are permitted to ſhed upon the Ground when they are ripe, the Plants will come up in Autumn, abide the Winter, and flower early in the ſucceeding Summer, and their Flowers will be much larger than thoſe which are ſown in the Spring.

The other Plants were moſt of them diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the *Royal Garden* at *Paris*, where they were cultivated, and have been ſince diſtributed to many curious Botanic Gardens. Theſe are all of them very hardy Plants, which will live in the open Air in *England*, and are all of them abiding Plants except the laſt, which is an Annual; ſo that the Seeds of this Kind muſt be ſown every Spring, and managed as hath been directed for the *Garden-clary*.

They are alſo propagated by Seeds, which ſhould be ſown in *March* on a Bed of freſh light Earth; and when the Plants are come up, they ſhould be carefully weeded, and thinned where they are too cloſe, leaving them about eight or ten Inches apart; and during the Summer Seaſon they muſt be kept clear from weeds, which is the only Culture they will require: The following *Michaelmas* they ſhould be taken up and tranſplanted where they are to remain, allowing them at leaſt two Feet of Room; becauſe, when they have obtained Strength, they will ſend forth a great Number of Shoots, and ſpread pretty much every way. Theſe Plants are preſerved in Botanic Gardens, for the ſake of Variety; but are ſeldom cultivated in other Places. For *Garden Clary*, ſee *Sclarea*.

HORNBEAM. *Vide* Carpinus.

HORSE-CHESNUT. *Vide* Hippocaſtanum.

HORSE-DUNG is of great Uſe to make Hot-beds for the raiſing all Sorts of Early Garden Crops, as *Cucumbers*, *Melons*, *Aſparagus*, *Salletting*, &c. for which Purpoſe no other Sort of *Dung* will do ſo well, this fermenting the ſtrongeſt, and, if mix'd with long Litter, and Sea-coal Aſhes in a due Proportion, will continue its Heat much longer than any other Sort of Dung whatſoever; and afterwards, when rotted, becomes an excellent Manure for moſt Sorts of Land, more eſpecially for ſuch as are of a cold Nature; and for ſtiff clayey Lands, when mix'd with Sea-coal Aſhes, and the Cleanſings of *London* Streets, it will cauſe the Parts to ſeparate much ſooner than any other Compoſt will do; ſo that where it can be obtain'd in Plenty, I would always recommend the Uſe of it for ſuch Lands.

HOSE IN HOSE, a Term us'd in Gardening, to ſignify one long Husk within another, as in the *Polyanthos*.

HOSE-HUSK, is a long round *Huſk*, as in *Pinks*, *Gillyflowers*, &c.

HOT-BEDS are of general Uſe in theſe Northern Parts of *Europe*, without which, we could not enjoy ſo many of the Products of warmer Climes as we do now; nor could we have the Tables furniſh'd with the ſeveral Products of the Garden, during the Winter and Spring Months, as they are at preſent in moſt Parts of *England*. The ordinary *Hot-beds* which are commonly us'd in the Kitchen-Gardens, are made with new Horſe-dung, in the following manner:

1ſt, Provide a Quantity of new Dung from the Stable (in which there ſhould be part of the Litter or Straw which is commonly us'd in the Stable) in proportion to the Length of the *Bed* intended; which, if early in the Year, ſhould not be leſs than one good Load for each Light; this Dung ſhould be thrown up in an Heap, mixing therewith a few Sea-coal Aſhes, which will be of Service to continue the Heat of the Dung; it ſhould remain ſix or ſeven Days, by which Time it will have acquir'd a due Heat: Then in ſome well-ſhelter'd Part of the Garden you muſt dig out a Trench in Length and Width proportionably to the Frames you intend it for, and, if the Ground be dry, about a Foot deep; but if wet, not above ſix Inches; then wheel the Dung into the Opening, obſerving to ſtir every Part of it with a Fork, and lay it exactly even and ſmooth thro' every Part of the *Bed*; as alſo to lay the Bottompart of the Heap (which is commonly free from Litter) upon the Surface of the *Bed*; this will prevent the Steam from riſing ſo plentifully as it would otherwiſe do: And if it be deſigned for a *Bed* to plant out *Cucumbers* or *Melons* to remain for good, you muſt make a Hole in the Middle of each Light about ten Inches over, and ſix deep, which ſhould be fill'd with good freſh Earth, thruſting a Stick into the Middle, to ſhew the Place where the Hole is; then cover the *Bed* all over with the Earth which was taken out of the Trench about four Inches thick, and cover it with the Frame, letting it remain until the Earth be warm, which commonly happens in two Days after the *Bed* is made; then you may place the Plants therein, as is directed for each Kind under their proper Heads.

But if your *Hot-bed* be deſign'd for other Plants, there need be no other Holes made in the Dung; but after having ſmoothed the Surface with a Spade, you ſhould cover the Dung about three or four Inches thick with good Earth, putting on the Frames and Glaſſes as before.

In the making of theſe *Hot-beds*, it muſt be carefully obſerv'd to ſettle the Dung cloſe with a Fork; and if it be pretty full of long Litter, it ſhould be equally trod down cloſe in every Part, otherwiſe it will be ſubject to heat too violently; and conſequently the Heat will be much ſooner ſpent, which is one of the greateſt Dangers this *Bed* may be liable to. During the firſt Week or ten Days after the *Bed* is made, you ſhould cover the Glaſſes but ſlightly in the Night, and in the Day-time carefully raiſe them to let out the Steam, which is ſubject to riſe very copiouſly while the Dung is freſh: but as the Heat abates, ſo the Covering ſhould be increas'd, otherwiſe the Plants in the *Beds* will be ſtunted in their Growth, if not intirely deſtroy'd. In order to remedy this Evil, if the *Bed* be very cold, you muſt put a pretty good Quantity of new hot Dung round the Sides of it, which will add a freſh Heat thereto, and cauſe it to continue a conſiderable Time after; and as the Spring advances, ſo the Sun will ſupply the Loſs of the Dung's Heat; but then it will be adviſeable to lay ſome Mowings of Graſs round the Sides of the *Bed*, eſpecially if the Nights ſhould prove cold, as it often happens in *May*, which is many times, even at that Seaſon, very hurtful to tender Plants on *Hot-beds*.

But although the *Hot-bed* I have deſcribed is what the Kitchen Gardeners commonly uſe, yet thoſe made with Tanner's

Bark are much more preferable, eſpecially for all tender Exotick Plants or Fruits, which require an even Degree of Warmth to be continu'd for ſeveral Months; which is what cannot be effected by Horſe-dung. The Manner of making theſe *Beds* is as follows:

You muſt dig a Trench in the Earth about three Feet deep, if the Ground be dry; but if wet, it muſt not be above a Foot deep at moſt, and muſt be rais'd two Feet above-ground. The Length muſt be proportion'd to the Frames intended to cover it; but that ſhould never be leſs than eleven or twelve Feet, and the Width not leſs than ſix, which is but a ſufficient Body to continue the Heat. This Trench ſhould be brick'd up round the Sides to the above-mentioned Height of three Feet, and ſhould be fill'd in the Spring with freſh Tanner's Bark, (*i. e.* ſuch as the Tanners have lately drawn out of their Vats, after they have us'd it for tanning Leather) which ſhould be laid in a round Heap for three or four Days before it is put into the Trench, that the Moiſture may the better drain out of it, which, if detain'd in too great a Quantity, will prevent its Fermentation; then put it into the Trench, and gently beat it down equally with a Dung-fork: But it muſt not be trodden, which would alſo prevent its heating, by ſettling too cloſe: Then you muſt put on the Frame over the *Bed*, covering it with the Glaſſes, and in about ten Days or a Fortnight it will begin to heat, at which time you may plunge your Pots of Plants or Seeds into it, obſerving not to tread down the Bark in doing of it.

A *Bed* thus prepar'd (if the Bark be new, and not ground too ſmall) will continue in a good Temper of Warmth for ſix Months; and when you find the Heat decline, if you ſtir up the Bark again pretty deep, and mix a Load or two of freſh Bark among the old, it will cauſe it to heat again, and preſerve its Warmth two or three Months longer: There are many People who lay ſome hot Horſe-dung in the Bottom of the Trench, under the Bark, to cauſe it to heat: but this is what I would never practiſe, unleſs I wanted the Bed ſooner than the Bark would heat of itſelf; and then I would put but a ſmall Quantity of Dung at Bottom, for that is ſubject to make it heat too violently, and will occaſion its loſing the Heat ſooner than ordinary; and there will never be any Danger of the Bark's heating, if it be new, and not put into the Trench too wet, tho' it may ſometimes be a Fortnight or more before it acquires a ſufficient Warmth; but then the Heat will be more equal and laſting.

The Frames which cover theſe Beds ſhould be proportion'd to the ſeveral Plants they are deſign'd to contain: For Example; if they are to cover the *Anana*, or *Pine-apple*, the back Part of the Frame ſhould be three Feet high, and the lower Part fifteen Inches, which will be a ſufficient Declivity to carry off the Wet; and the Backſide will be high enough to contain the Plants that are in Fruit, and the lower Side will be ſufficient for the ſhorteſt Plants; ſo that, by placing them regularly according to their Height, they will not only have an equal Diſtance from the Glaſſes, but alſo appear much handſomer to the Sight. And although many People make their Frames deeper than what I have allotted, yet I am fully perſuaded, that where there is but Height enough to contain the Plants, without bruiſing their Leaves, it is much better than to allow a larger Space; for the deeper the Frame is made, the leſs will be the Heat of the Air incloſ'd therein, there being no artificial Warmth but what the Bark affords, which will not heat a large Space of Air: And as the *Pine-apple* requires to be conſtantly kept very warm, in order to ripen the Fruit well; ſo it will be found, upon Trial, that the Depth I have have allowed will anſwer that Purpoſe better than a greater.

But if the *Bed* be intended for taller Plants, then the Frame muſt be made in Depth proportionable thereto: but if it be for ſowing of Seeds, the Frame need not be above fourteen Inches high at the Back, and ſeven Inches deep in the Front, by which Means the Heat will be much greater; and this is commonly the Proportion allow'd to the Frames uſually made uſe of in the Kitchen-gardens. As to their Length, that is generally according to the Fancy of the Owner; but they commonly contain three Lights each, which is in the Whole about eleven Feet in Length; though ſometimes they are made to contain four Lights; but this is too great a Length: The Frames thus made are not ſo handy to remove, as when they are ſhorter, and are more ſubject to decay at their Corners. Some indeed have them to contain but two Lights, which is very handy for raiſing *Cucumber* and *Melon* Plants while young; but this is too ſhort for a Bark-bed, as not allowing Room for a proper Quantity of Bark to continue a Warmth for any conſiderable Time, as was before mentioned; but for the other Purpoſes, one or two ſuch Frames are very convenient.

As to thoſe Frames which are made very deep, it is much the better Way to have them made to take aſunder at the four Corners, ſo that they may be remov'd with Eaſe; otherwiſe it will be very difficult to take the Frame off when there is Occaſion to put in new Bark, or take out the old. The Manner of making theſe Frames is generally known, or may be much better conceiv'd by ſeeing them than can be expreſs'd in Writing, therefore I ſhall forbear ſaying any thing more on this Head.

HOTTONIA, Water-Violet.

The *Characters* are;

It hath a Roſe-ſhaped Flower conſiſting of one Leaf, which is divided into five Parts almoſt to the Bottom; in the Center of the Flower ariſes the Pointal, which afterward becomes a cylindrical Fruit, in which are contained ſeveral ſpherical Seeds.

We have but one *Kind* of this Plant, *viz.*

HOTTONIA, *Boerh. Ind. alt.* Water-Violet.

This Plant is very common in deep ſtanding Waters, and Ditches, in ſeveral Parts of *England*. The Leaves of this Plant appear on the Surface of the Water the Beginning of *April*, and in *May* the Flowers appear on pretty long naked Stalks, growing in a Spike. Theſe Flowers are of a fine roſe Colour, which, together with their fine cut Leaves make a beautiful Appearance on the Water.

It may be propagated in deep ſtanding Waters, by procuring its Seeds when they are ripe, from the Places of their natural Growth; which ſhould be immediately dropp'd into the Water where they are deſigned to grow, and the Spring following they will appear; and if they are not diſturbed, they will ſoon propagate themſelves in great Plenty.

HOUGHING is neceſſary and beneficial to Plants, for two Things: 1ſt, for deſtroying of Weeds; 2dly, becauſe it diſpoſes the Ground the better to imbibe the Night Dews, and keep it in a conſtant Freſhneſs, and adds a Vigour to the Trees, whoſe Fruit, by that means, becomes better-conditioned than otherwiſe it would be.

HUMIDITY, is the *Quality* commonly call'd *Moiſture*, or the Power of wetting others, which Quality ſome Liquo and Fluids are endowed with; and it differs very much fro *Fluidity*, in that it depends altogether on the Congruity of th component Particles of any Liquor to the Pores or Surfaces o ſuch particular Bodies as it is capable of adhering to.

Thus *Quickſilver* is not a moiſt Liquor, in reſpect to ou Hands or Cloaths; and many other Things it will not ſtic to: but it may be call'd a moiſt Liquor, in reſpect to Gold Lead, or Tin, to the Surfaces of which it will preſently adhere.

Nay, Water itſelf, that wets almoſt every thing, and is th great Standard of *Humidity* or *Moiſture*, is not capable o wetting every thing; for it ſtands, and runs eaſily off in globular Drops on the Leaves of *Cabbages*, and many other Plant and will not wet the Feathers of *Ducks*, *Swans*, and othe Water-fowl.

And it is very plain, that it is only the Texture that ma cauſe the Fluid to be humid; becauſe neither *Quickſilver* alone nor *Biſmuth*, will ſtick upon Glaſs: yet being mix'd togethe they will form a Maſs that will ſtick on it, as is very we known in the foliating of Looking-glaſſes, in which ſuch Compoſition is uſed.

HURA, the Sand Box-tree.

The *Characters* are;

It hath a funnel-ſhaped Flower conſiſting of one Leaf, whi is ſpread open at the Brim, and ſlightly cut into twelve Part at the Bottom of the Tube is placed the Pointal, which afte ward becomes a globular compreſſed Fruit, which has twel Cells, in each of which is contained one roundiſh flat Seed.

We know but one *Sort* of this Plant, *viz.*

1. HURA *Americana, abutili Indici folio. H. Amſt.* *American* Hura, with a Leaf like the *Indian* Abutilon. This ſometimes called *Jamaica Walnuts*, and the *Sand Box-tr* and by others *Warnelia* and *Havelia*.

This Shrub is a Native of the *Spaniſh Weſt-Indies*, fro whence the Seeds have been brought into ſeveral Iſlands in t *Weſt-Indies*, where the Inhabitants cultivate theſe Plants their Gardens by way of Curioſity. It riſes to the Height fourteen or ſixteen Feet, and divides towards the Top i

ſeve

ſeveral Branches, which are adorned with large Leaves indented on their Edges, and terminating in a Point; theſe Leaves, as alſo the younger Branches, are of a deep green Colour, and are full of a milky Juice, which iſſues out on their being broken or bruiſed. The Fruit of this Plant, if ſuffered to remain on till they are fully ripe, burſt in the Heat of the Day with a violent Exploſion, making a Noiſe like the firing of a Piſtol, and hereby the Seeds are thrown about to a conſiderable Diſtance. Theſe Seeds, when green, vomit and purge, and are ſuppoſed to be ſomewhat akin to the *Nux Vomica*.

The Seeds of this Plant were ſent from *Carthagena* in *New Spain*, by the late Dr. *William Houſtoun*; and ſince there have been many of the Seeds ſent into *England* from *Barbadoes*, where there are many of the Plants cultivated in the Gardens of the Curious.

It is propagated by Seeds, which ſhould be ſown early in the Spring in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth frequently; and if the Night ſhould prove cold, the Glaſſes of the Hot-bed muſt be covered with Mats, to preſerve a gentle Warmth in the Bed; but when the Days are warm, the Glaſſes of the Hot-bed ſhould be raiſed to admit freſh Air, as alſo to let the Steam of the Bed paſs off: If theſe Rules are duly obſerved, the Plants will appear in about five Weeks after the Seeds are ſown, when they ſhould be carefully cleared from Weeds, and frequently refreſhed with Water. As the Plants will advance very faſt, where due Care is taken of them; ſo they ſhould have a large Share of freſh Air admitted to them in warm Weather, otherwiſe they will draw up too weak. When the Plants are about four Inches high, they ſhould be tranſplanted each into a ſeparate ſmall Pot filled with light rich Earth, and plunged again into the Hot-bed of Tanners-bark, being careful to ſhade them from the Heat of the Sun, until they have taken new Root; after which Time they muſt have free Air admitted to them, by raiſing of the Glaſſes in proportion to the Warmth of the Seaſon, and they ſhould be frequently watered. When the Plants have filled theſe ſmall Pots with their Roots, they muſt be ſhaken out of them, and their Roots trimmed, and then placed in larger Pots; which ſhould be filled with the like rich Earth, and plunged again into the Hot-bed, where they ſhould remain till *Michaelmas*, provided the Plants have Room, without touching of the Glaſſes; at which time they muſt be removed into the Bark-ſtove, and plunged in the warmeſt Part thereof: during the Winter Seaſon they muſt be often watered; but they muſt not have it in ſuch Quantities then, as is given to them in Summer; they muſt alſo be kept very warm, otherwiſe they will not live in this Country. In Summer they muſt have a large Share of freſh Air in warm Weather, but they muſt not be removed into the open Air, for they are too tender to live abroad in the warmeſt Part of the Year in this Country.

There are many of theſe Plants now growing in the Stoves in *England*, ſome of which are eight or ten Feet high; but I have ſeen but one Plant of this Kind in Flower, which was in the Gardens of the Right Honourable Lord *Petre*, at *Ingateſtone-hall* in *Eſſex*.

As theſe Plants have ample Leaves, which are of a beautiful green Colour, ſo they afford an agreeable Variety among other tender exotic Plants in the Stove; for where they are kept warm, and duly refreſhed with Water, they retain their Leaves all the Year in Verdure.

The Fruit of this Plant is, by the Inhabitants of the *Weſt-Indies*, cut open on the Side where the Footſtalk grew, and the Seeds carefully taken out, and the Shells are uſed as a Standiſh, to contain Sand for Writing; which gave Riſe to the Name of Sand-box. When theſe Fruit are brought intire into *England*, it is very difficult to preſerve them; for when the Heat of the Summer comes on, they uſually burſt with an Exploſion, and ſcatter their Seeds about.

HYACINTHUS, [Ὑάκινθος, Gr.] Hyacinth, or Jacinth.

The *Characters* are;

It hath a bulbous Root: The Leaves are long and narrow: The Stalk is upright and naked; the Flowers growing on the upper Part in a Spike: The Flowers conſiſt each of one Leaf, are naked, tubuloſe, and cut into ſix Diviſions at the Brim, which are reflexed: The Ovary becomes a roundiſh Fruit with three Angles, which is divided into three Cells that are fill'd with roundiſh Seeds.

The *Species* are;

1. HYACINTHUS *Anglicus, flore cæruleo. Ger.* Blue Engliſh Hair-bells.

2. HYACINTHUS *Anglicus, flore albo. Ger.* White Engliſh Hair-bells.

3. HYACINTHUS *Anglicus, flore incarnato.* Fleſh-colour'd Engliſh Hair-bells.

4. HYACINTHUS *Orientalis brumalis præcociſſimus, flore albo. Boerh. Ind.* The earlieſt White Oriental Hyacinth, *commonly call'd* Januarius.

5. HYACINTHUS *Orientalis brumalis, flore pallidè cæruleo. Boerh. Ind.* Oriental Jacinth, with a pale blue Flower, *commonly call'd* The Imperial.

6. HYACINTHUS *Orientalis albus primus. C. B.* Common Oriental Jacinth, with a white Flower.

7. HYACINTHUS *Orientalis major præcox, dictus* Zimbul *Indi. Park. Par.* The great Oriental Jacinth, *commonly call'd* Zimbul Indi.

8. HYACINTHUS *Orientalis maximus, flore amœne cæruleo, polyanthus. H. R. P.* The greateſt Eaſtern Jacinth, with many Flowers of a fine blue Colour.

9. HYACINTHUS *Orientalis, flore pleno cæruleo, vel purpureo-violaceo. Park. Par.* The Double blue Oriental Jacinth.

10. HYACINTHUS *Orientalis candidiſſimus, flore pleno. Park. Par.* The whitiſh double Oriental Jacinth.

11. HYACINTHUS *Orientalis, multiplici flore pallidè incarnatus. H. L.* Double Oriental Jacinth, with a pale fleſh-colour'd Flower, *commonly call'd* The Pulchra.

12. HYACINTHUS *Orientalis, flore pleno, cæruleo-purpureo, clavo longo, petalis modice reflexis. Boerh. Ind.* Double blue Oriental Jacinth, with a long Style, and the Petals moderately reflexed, *commonly call'd* The Double Cardinal.

13. HYACINTHUS *Orientalis, flore pleniſſimo albo, intus eleganter roſeo, clavo conico obtuſo, petalis valde reflexis. Boerh. Ind.* The moſt double Oriental Jacinth, with a white Flower of an elegant Roſe-colour in the Middle, and the Petals greatly reflexed, *commonly call'd* The King of Great Britain.

14. HYACINTHUS *Orientalis, flore pleniſſimo candidiſſimo toto & intus, clavo conico obtuſo, petalis valde reflexis. Boerh. Ind.* The moſt double Oriental Jacinth, with a pure white Flower, and the Petals greatly reflexed, *commonly call'd* The Queen of Great Britain.

15. HYACINTHUS *Orientalis, flore pleno lacteo, lituris carneis, clavis longis. Boerh. Ind.* Double Oriental Jacinth, with a Milk-colour'd Flower, ſtreak'd with a pale Red, *commonly call'd* Claudius Albinus.

16. HYACINTHUS *Orientalis, flore pleniſſimo carneo, lituris roſeis, clavo conico longiſſimo, intus roſeo, petalis valde reflexis. Boerh. Ind.* The moſt double Oriental Jacinth, with a Fleſh-colour'd Flower, ſtreak'd with a Roſe-colour, and the Petals greatly reflexed, *commonly call'd* Apollo.

17. HYACINTHUS *Orientalis, flore pleno ſqualide candido, clavo ad baſin utriculato, longo petalis valde reflexis. Boerh. Ind.* Double Oriental Jacinth, with a dirty-white Flower, and reflexed Petals, *commonly call'd* Agaath Mignon.

18. HYACINTHUS *Orientalis, flore pleniſſimo albo, pauxillo carnei admiſto, clavo longo anguloſo plano, ore ampliſſimo. Boerh. Ind.* Double Oriental Jacinth, with a Flower intermix'd with very little fleſh-colour'd Spots, *commonly call'd* Claudius Civilis.

19. HYACINTHUS *Orientalis, flore pleniſſimo, carneo & corallino rubro, clavo craſſo brevi, petalis maxime reflexis. Boerh. Ind.* Oriental Jacinth, with a very double red Coral-colour'd Flower, and the Petals greatly reflexed, *commonly call'd* Coralline.

20. HYACINTHUS *Orientalis, flore pleniſſimo candidiſſimo, in fundo oris roſeo. Boerh. Ind.* Oriental Jacinth, with a very double pure white Flower, and the Bottom of the Rim of a Roſe-colour, *commonly call'd* The Queen of Flowers.

21. HYACINTHUS *Orientalis, flore pleniſſimo candidiſſimo, petalis anguſtis & magis acutis.* Oriental Jacinth, with a very double pure white Flower, with narrow ſharp-pointed Petals, *commonly call'd* The King of Flowers.

22. HYACINTHUS *Orientalis, flore pleniſſimo candidiſſimo toto, clavo conico, petalis maxime reflexis, caule & flore maximis. Boerh. Ind.* Oriental Jacinth, with a very double white Flower, and the Petals very much reflexed, and large Stalks and Flowers, *commonly call'd* Kaiſar's White Jewel.

23. HYACINTHUS *Orientalis, flore pleniſſimo candido carneo, lituris rubellis, clavo breviſſimo craſſiſſimo. Boerh. Ind.* Oriental Jacinth, with double white Flowers ſtreak'd with red, *commonly call'd* The Princeſs Royal.

Beſides theſe here mentioned, there are a great Variety of fine Double *Hyacinths*, with beautiful variegated Flowers, moſt of which have Names impoſed on them according to the Fancy of their Owners; and ſome of theſe are highly eſteem'd by the Floriſts in *Holland*, where, according to their printed Catalogues, they have many Flowers which are valued at five, ſix, ſeven, eight, or ten Pounds *per* Root; but as theſe are Varieties which have been obtained from Seeds, ſo the Number of them are continually increas'd where People do conſtantly ſow of their Seeds; and thoſe new Flowers which are rais'd, if they are large, beautiful, and very double, will always be much valu'd at firſt, until there has been a good Number of Roots obtained from them; after which they conſtantly decreaſe in their Value according to their Plenty. But to enumerate all the Sorts that are now printed in the *Dutch* Catalogues, would be to no Purpoſe in this Place, therefore I ſhall only mention ſome of the ſtarry *Hyacinths*, and afterwards proceed to their Culture:

1. Hyacinthus *ſtellaris bifolius Germanicus. C. B. P. flore cœruleo.* Early blue ſtarry Hyacinth, *vulgo.*
2. Hyacinthus *ſtellaris bifolius, Germanicus, flore exalbido. Boerh. Ind.* Early white ſtarry Hyacinth, *vulgo.*
3. Hyacinthus *ſtellaris Byzantinus. Cluſ.* Great ſtarry Hyacinth, *vulgo.*
4. Hyacinthus *ſtellaris cœruleus amœnus. C. B. P.* Fine blue ſtarry Hyacinth.
5. Hyacinthus *ſtellatus Peruanus. H. Eyſt.* Blue ſtarry Hyacinth of *Peru.*
6. Hyacinthus *ſtellatus Peruanus, flore albo.* White ſtarry Hyacinth of *Peru.*

The firſt of theſe Species is a Native of *England*, growing in Woods, and under Hedges in divers Parts, but eſpecially near *London*. The two next mentioned are Varieties which have been accidentally obtain'd from the firſt, from which they differ only in the Colour of their Flowers. The twenty next mentioned are all of them Varieties of the Oriental *Hyacinths*, which were originally brought from *Aſia*; but by the Induſtry of the Floriſts in *Holland* and *Flanders*, they have been ſo much improv'd, as to become one of the moſt ornamental Flowers of the Spring: And as they continue ſowing Seeds annually of theſe Flowers, ſo they not only increaſe the Numbers of their Flowers, but have yearly ſome extraordinary Beauties appear; which are, according to their Stature, Beauty, and other Properties, highly eſteem'd, and are ſometimes bought at a very great Expence by the curious Delighters in theſe Beauties.

The firſt and ſecond Sorts of the ſtarry *Hyacinths* are found in ſome Parts of *Germany*: The firſt is alſo a Native of *England*; the ſecond being only a Variety of the firſt, which probably was obtain'd from Seeds: The third and fourth Sorts were brought from *Conſtantinople*; and the fifth and ſixth Sorts, tho', by their Names, ſuppos'd to be brought from *Peru*, yet are they found in many Places in the *Levant*, and Monſ. *Tournefort* mentions them as Natives of *Portugal*; but my ingenious Friend Mr. *Henry Hopkey* ſent me ſome Seeds of them which he gather'd upon *Gibraltar* Hills, where he found them growing in great Plenty. The two firſt mentioned do flower in *February*, which cauſes them to be greatly eſteemed. The third and fourth Sorts produce their Flowers in *April*; but the fifth and ſixth do not flower until the Middle of *May*: ſo that they keep a regular Succeſſion from the Middle of *February* until the End of *May*; and if their Roots are permitted to remain three Years undiſturb'd, they will produce many Stems of Flowers from each Tuft, whereby they will make a very beautiful Appearance, and continue the Succeſſion much better than when they are tranſplanted every Year, and their Flowers will be much ſtronger.

All the different Sorts of *Hyacinths* are propagated by Seeds or Off-ſets from the old Bulbs: The former Method has been but little practiſed in *England* 'till very lately; but in *Holland* and *Flanders* it hath been continually follow'd for many Years, whereby they have obtain'd a very great Variety of the moſt beautiful Flowers of this Kind; and it is owing to the Induſtry of the Floriſts in thoſe Countries, that the Lovers and Delighters in Gardening are ſo agreeably entertain'd, not only with the curious Variety of this, but of moſt other bulbous-rooted Flowers; few other Floriſts thinking it worth their Trouble to wait four or five Years for the Flowers of a Plant, which, when produced, perhaps there might not be one in forty that may deſerve to be preſerv'd: but they did not conſider, that it was only the Loſs of the three or four firſt Years after ſowing; for if they continued ſowing every Year after they began, there would be a Succeſſion of Flowers annually, which would conſtantly produce ſome Sorts that might be different from what they had before ſeen; and new Flowers being always the moſt valuable by ſkilful Floriſts, (provided they have good Properties to recommend them) it would always be a ſufficient Recompence for their Trouble, and Loſs of Time.

The Method of raiſing theſe Flowers from Seed, is as follows: Having provided yourſelf with ſome good Seed, (which ſhould be ſaved from either ſemi-double, or ſuch ſingle Flowers as are large, and have good Properties) you muſt have a Parcel of ſquare ſhallow Boxes or Pots, which muſt be fill'd with a freſh, light, ſandy Soil, laying the Surface very level; then ſow your Seeeds thereon as equally as poſſible, covering it about half an Inch thick with the ſame light Earth: The Time for this Work is about the Beginning of *Auguſt*: Theſe Boxes or Pots ſhould be placed where they may enjoy the Morning-Sun only until the Middle or latter End of *September*, at which Time they ſhould be remov'd into a warmer Situation; and towards the End of *October* they ſhould be placed under a common Hot-bed Frame, where they may remain during the Winter and Spring Months, that they may be protected from hard Froſts; tho' they ſhould be expoſed to the open Air at all times when the Weather is mild. In *February* the young Plants will begin to appear above-ground: at which time they muſt be carefully ſkreen'd from Froſts, otherwiſe it will prove very injurious to them: but you muſt never cover 'em at that Seaſon, but in the Night, or in very bad Weather; for when the Plants are come up, if they are cloſe cover'd, they will draw up very tall and ſlender, and thereby prevent the Growth of their Roots. In the Middle of *March*, if the Weather proves good, you may remove the Boxes out of the Frame, placing them in a warm Situation; obſerving, if the Seaſon be dry, to refreſh them now and then with a little Water, as alſo to keep them very clear from Weeds, which would ſoon over-ſpread the tender Plants, and deſtroy them, if permitted to remain.

Towards the latter End of *April*, or the Beginning of *May*, theſe Boxes ſhould be remov'd into a cooler Situation; for the Heat of the Sun at that Seaſon would be too great for theſe tender Plants, cauſing their Blades to decay much ſooner tha they would if they were ſkreen'd from its Violence: In thi ſhady Situation they ſhould remain during the Heat of Summer, obſerving to keep them conſtantly clear from Weeds but you muſt not place them under the Dripping of Trees &c. nor ſhould you give them any Water after their Blad are decay'd, for that would infallibly rot the Roots. Abou the Middle or Latter-end of *Auguſt* you ſhould ſift a little lig rich Earth over the Surface of the Boxes, and then remo them again into a warmer Situation, and treat them, duri the Winter, Spring, and Summer Months, as was before d rected; and about the Middle of *Auguſt* you ſhould prepare Bed of light, rich ſandy Soil, in Proportion to the Quantity your Seedling Plants, and having levell'd the Surface very eve you ſhould take out the Earth from the Boxes in which yo Plants were rais'd, into a Sieve, in order to get out all t Roots, which by this time (if they have grown well) will about the Thickneſs of a ſmall Quill: theſe Roots ſhould placed upon the Bed at about two or three Inches aſunder, o ſerving to ſet the bottom Part of their Roots downwards; th cover them over two Inches thick with the ſame light Eart but as it will be impoſſible to get all the ſmall Roots out of t Earth in the Boxes, ſo you ſhould ſpread the Earth upon a other Bed equally, and cover it over with light Earth; which Method you will not loſe any of the Roots, be th ever ſo ſmall.

Theſe Beds muſt be arched over with Hoops, and in v hard froſty Weather they muſt be cover'd with Mats, &c. protect 'em from Froſt; and in the Spring, when the gr Leaves are above Ground, if the Weather ſhould be very d you muſt refreſh 'em with Water: but do this ſparingly; nothing is more injurious to theſe Bulbs, than too gr Quantities of Moiſture. During the Summer-ſeaſon you m conſtantly keep the Beds clear from Weeds; but after Blades are decay'd, you muſt never give them any Wat And in Autumn you ſhould ſtir the Surface of the Bed wi very ſhort Hand-fork, being exceeding careful not to thru ſo deep as to touch the Roots, which, if hurt, are very ject to periſh ſoon after: Then ſift a little freſh, light, Earth over the Bed about an Inch thick, or ſomewhat mo and in Winter cover 'em again, (as was before directed): this Bed the Roots may continue until they flower, whic commonly five Years after ſowing, obſerving to treat ' both in Summer and Winter, as before.

When their Flowers begin to ſhew themſelves, you ſh mark all ſuch as appear to have good Properties, by thruſti ſmall Stick down by each Root; which Roots, at the T for taking them up, ſhould be ſelected from the reſt, planted by themſelves: Tho' I would by no means adviſe rejecting any of the other Roots, until they have blown Years, before which you cannot be aſcertained of their V

W

When the green Leaves of theſe Plants begin to decay, their Roots muſt be taken up; and the Earth of the Bed being rais'd into a Ridge, the better to ſhoot off the Moiſture, they ſhould be laid into the Earth again in an horizontal Poſition, leaving the green Leaves hanging downwards from the Roots, whereby the great Moiſture contained in their very ſucculent Leaves and Flower-ſtalks is exhaled, and prevented from entring the Roots; which, when ſuffer'd to return into them, is very often the Cauſe of their rotting: In this Ridge the Roots ſhould remain until the Leaves are quite dried off, when they muſt be taken up; and after being cleared of all manner of Filth, which would be hurtful to them, they muſt be laid up in Boxes, where they may be preſerved dry until *September*, which is the proper Seaſon for planting them again. The Method of doing this, ſhall be hereafter mentioned, when we treat of the Management of old Roots.

The *Hyacinth* of *Peru* may alſo be raiſed from Seeds in the ſame manner as the common *Hyacinths*, with this Difference only, that as they ſeldom loſe their green Leaves or their Fibres, ſo their Roots muſt not be kept out of the Ground, but ſhould be planted again immediately when they are taken up. The beſt Seaſon for this Work is in *Auguſt*: And they ſhould be planted in a Border expoſed to the Morning Sun; for if they are planted in a very hot Situation, the Flowers decay ſoon after they are expanded, ſo that they ſeldom continue in Beauty above a Week; whereas, if they are ſkreen'd from the violent Heat of the Sun, they may be preſerved near three Weeks, and will have a greater Number of Flowers open at once upon the ſame Stem.

I ſhall now proceed to the Culture of ſuch *Hyacinths* as have either been obtained from *Holland*, or are of our own Product from Seeds, that are very beautiful, and worthy to be preſerved in Collections of good Flowers; and it hath been the want of Skill in the Management of theſe noble Flowers, which has occaſion'd the ill Succeſs moſt People have had with them in *England*, whereby they are almoſt entirely neglected, ſuppoſing their Roots degenerate after they have flower'd in *England*: Which is a great Miſtake; for were the Roots managed with the ſame Art as is practiſed in *Holland*, I am fully convinced they would thrive full as well in *England* as they do in *Holland*, or elſewhere, as I have experienced; for, from about an hundred Roots which I have received from *Holland* at wo or three different times, I have increaſed them to almoſt double the Number of ſtrong Roots, all which flower'd in the Spring *Anno* 1730, ſtronger than they did when I firſt received them; and I dare ſay they were as large, and produced as many Flowers upon their Stems, as the ſame Sorts ever did in *Holland*: And by Letters which I have lately receiv'd from my ery worthy ingenious Friend *James Juſtice* Eſq; near *Edinurgh*, he hath ſucceeded ſo well in the Management of theſe lowers, as to equal any of the *Dutch* Floriſts in the Number nd Strength of his Flowers: And he has raiſed great Quantiies of Flowers from Seed of his own ſaving, from amongſt which he has obtain'd a moſt extraordinary fine one, which he alls *The Royal Britiſh Star*; the Height of its Stem was wenty Inches, upon which were twenty-three Bells, or Flows, placed in a pyramidal Order, each of which was very arge and double, of an extraordinary white Colour on the Upper part of the Petals; but the Lower-part or Centre of the Flower of a very deep Violet Colour. This Flower is thought, y ſeveral curious Gentlemen (who have ſeen the fine Collectins of *Hyacinths* in the *Dutch* Gardens) to be equal to, if not xceeding any Flowers they have ſeen in *Holland*. But to proeed:

The Soil in which theſe Flowers do ſucceed beſt, is a light, ndy, freſh, rich Earth, which may be compos'd after the ollowing Manner: Take half freſh Earth from a Common or Paſture Land which is of a ſandy Loam; this ſhould not be aken above eight or nine Inches deep at moſt; and if you take he Turf or Green-ſward with it, it will ſtill be better, provided you have Time to let it rot; to this you ſhould add a fourth-part of Sea-ſand, and the other fourth-part of rotten Cow-dung; mix theſe well together, and caſt it into an Heap, where it may remain until you uſe it, obſerving to turn it over once in three Weeks, or a Month. If this Compoſt be made wo or three Years before it be uſed, it will be much the better: But if you are obliged to uſe it ſooner, then it ſhould be oftener urn'd, that the Parts may the better unite.

This Soil ſhould be laid ten Inches deep on the Beds which re deſigned for your *Hyacinths*; and you may lay a little rotten Cow-dung or Tanners-bark at the Bottom, which may be within reach of the Fibres; but it ſhould by no means touch e Bulb. If the Soil be very wet where theſe Beds are made, u ſhould raiſe 'em ſeven or eight Inches above the Surface; t if it be dry, they need not be raiſed above three Inches.

The Manner of preparing the Beds, is as follows: Firſt, take all the former old Earth out of the Bed to the Depth you intend, then ſpread a little rotten Dung or Tan in the Bottom, laying it very level; upon this you ſhould lay the above-mention'd Earth five Inches thick, levelling it very even; then ſcore out the Diſtances for the Roots, which ſhould be eight Inches ſquare, in ſtrait Rows each Way; after which, place your Roots exactly in the Squares, obſerving to ſet the Bottom-part downward; then cover the Roots five Inches deep with the ſame prepared Earth; being very careful, in doing of this, not to diſplace any of them: And if the Tops of theſe Beds are made a little rounding, to ſhoot off the Wet, it will be of Service, provided they are not made too high, which is a Fault the other Way.

The beſt Seaſon for planting theſe Roots is towards the Middle or latter End of *September*, according to the Earlineſs or Lateneſs of the Seaſon, or the Weather which then happens: But I would adviſe you, never to plant 'em when the Ground is extreme dry, unleſs there be a Proſpect of ſome Rain ſoon after; for if the Weather ſhould continue dry for a conſiderable Time after, the Roots would receive a Mouldineſs, which will certainly deſtroy them.

Theſe Beds will require no farther Care until the Froſt comes on ſevere, at which Time they ſhould have ſome Peaſe-haulm, or ſuch-like Covering, laid over them, which will keep out the Froſt better than Mats, and lying hollow, will admit the Air to the Surface of the Ground, and alſo permit the Exhalations to paſs off, whereby the Earth will remain dry, and prevent the Roots from rotting; which has often happen'd when the Beds have been too cloſe covered. But you muſt obſerve to take off this Covering whenever the Weather is mild, and only let it continue on in very hard Froſts; for a ſmall Froſt cannot injure the Roots before the green Leaves appear above Ground, which is ſeldom before the Beginning of *February*; at which Time the Beds muſt be arched over with Hoops, that they may be cover'd either with Matts, Canvas, or ſome other light Covering, to prevent the Froſt from hindering the Buds as they ariſe above-ground: But theſe Coverings muſt be conſtantly taken off every Day when the Weather is mild, otherwiſe the Flower-ſtems will be drawn up to a great Height, and become very weak; and the Pedicles of the Flowers will be long and ſlender, and ſo render'd incapable of ſupporting the Bells: Which is a great Diſadvantage to the Flowers; for one of their greateſt Beauties conſiſts in the regular Diſpoſition of their Bells.

When the Stems of the Flowers are advanced to their Height, before the Flowers are expanded, you ſhould place a ſhort Stick down by each Root, to which with a Wire form'd into a Hoop, the Stem of the Flowers ſhould be faſten'd, to ſupport them from falling; otherwiſe, when the Bells are fully expanded, their Weight will incline them to the Ground, eſpecially if they are permitted to receive a Shower of Rain.

During their Seaſon of flowering, they ſhould be cover'd in the Heat of the Day from the Sun, as alſo from all heavy Rains: but they ſhould be permitted to receive all gentle Showers, as alſo the Morning and Evening Sun: but if the Nights are froſty, they muſt be conſtantly defended therefrom. With this Management, you may continue your *Hyacinths* in Beauty at leaſt one whole Month, and ſometimes more, according to their Strength, or the Favourableneſs of the Seaſon.

When their Flowers are quite decay'd, and the Tops of their Leaves begin to change their Colour, you muſt carefully raiſe the Roots out of the Ground with a narrow Spade, or ſome other handy Inſtrument, and then raiſe the Earth of your Beds into a high, ſharp Ridge, laying the Roots into it in an horizontal Poſition, with their Leaves hanging out; by which means a great Part of the Moiſture contained in their thick ſucculent Stalks and Leaves will evaporate, which, if it were permitted to return back to the Roots, would cauſe them to rot and decay after they are taken up, which has been the general Defect of moſt of the *Hyacinths* in *England*.

In this Poſition the Roots ſhould remain until the green Leaves are intirely dried up, which perhaps may be in three Weeks Time, then you muſt take them out of the Ground, and wipe them clean with a ſoft woollen Cloth, taking off all the decay'd Parts of the Leaves, and Fibres, putting them into open Boxes where they may lie ſingly, and be expoſed to the Air: But they muſt be preſerved carefully from Moiſture; nor ſhould they be ſuffered to remain where the Sun may ſhine upon them: In this Manner they may be preſerved out of the Ground until *September*, which is the Seaſon for replanting them again; at which Time you muſt ſeparate all the ſtrong flowering Roots, planting them in Beds by themſelves, that they may make an equal Appearance in their Flowers: But the Off-ſets and ſmaller Roots ſhould be planted in another ſeparate Bed for one Year, in which Time they will acquire

Strength, and by the ſucceeding Year will be as ſtrong as the older Roots.

The ſingle and ſemi-double Flowers ſhould be planted alſo in a Bed by themſelves, where they ſhould be carefully ſhelter'd (as was directed before) from the Froſt, until the Flowers are blown; at which Time their Covering ſhould be intirely removed, and they ſuffered to receive the open Air; which, tho' it may ſoon deface the Beauty of the Flowers, yet it is abſolutely neceſſary to promote their ſeeding: and when the Seeds are quite ripe, you muſt cut off the Veſſels, and preſerve them, with the Seeds therein, until the Seaſon for ſowing it. But you muſt obſerve, that after theſe Flowers have produced Seeds, they ſeldom flower ſo well again, at leaſt not in two Years after; ſo that the beſt Method to obtain good Seeds, is to plant new Roots every Year for that Purpoſe.

The common *Engliſh* and *ſtarry Hyacinths* are very hardy Plants, as are ſome of the ſingle blue and white Oriental Sorts, and do increaſe very faſt by Off-ſets from the old Roots; ſo that it is hardly worth while to propagate them by Seeds, eſpecially ſince it can ſcarcely be expected to receive any great Varieties from them: Theſe Flowers, tho' common, are very pretty Ornaments in the Borders of the Flower-Garden, where being intermix'd with other bulbous-rooted Flowers, they add to the Variety, and continue the Succeſſion of Flowers a long Time in the Spring; and as they are very hardy, and only require to be tranſplanted every other Year, ſo they are worthy of a Place in every good Garden.

The *Hyacinth* of *Peru* is one of the lateſt Flowers of all this Tribe, ſeldom appearing before the Middle, and ſometimes not until the latter End of *May:* This, as I before obſerved, ſhould have a Situation expoſed to the Morning Sun, and a light rich Soil: But as this ſeldom loſes its Leaves or Fibres entirely, ſo it cannot be kept long out of the Ground; the beſt Seaſon for tranſplanting their Roots is in *Auguſt* or *September*; at which Time the Off-ſets ſhould be taken from them, and the ſtrong Roots planted again for flowering; but the ſmall Roots ſhould be placed in a Nurſery-bed, until they have acquired Strength to flower. The Diſtance and Depth of planting theſe, being much the ſame with what I have already mention'd for the other *Hyacinths*, I ſhall forbear repeating it.

I ſhall add in this Place another *Hyacinth*, which is now preſerved in curious Collections of exotick Plants; it was originally brought from the *Cape of Good Hope*; and being a Native of a warm Climate, will not endure the Cold of our Winters in the open Air; but, for the Beauty of its Flowers, well deſerves a Place in a Green-houſe: It is called,

HYACINTHUS *Africanus tuberoſus, flore cæruleo umbellato. Breyn. prod.* The *African* Hyacinth, with a tuberoſe Root, and blue Flowers, growing in Umbels.

The Roots of this Plant ſhould be put in Pots, filled with the ſame Earth as was directed for the other *Hyacinths:* Theſe Pots during the Summer-ſeaſon, may be expoſed to the open Air with other Green-houſe Plants, and in Winter muſt be houſed with them. The Time for tranſplanting the Roots, is towards the End of *March*, before the green Leaves are produced too far; after which it is not ſafe ſo to remove them. During the Time that their green Leaves are in Vigour, they muſt be frequently watered: But when their Leaves begin to decay, it muſt be given them very ſparingly; for much Wet at that Time will rot their Roots: They ſhould alſo have as much free open Air, when the Weather is mild, as they can poſſibly receive; for which Purpoſe they ſhould be placed near the Windows of the Green-houſe; for they require only to be ſhelter'd from Froſt, and extreme cold Air, being in other reſpects very hardy.

This Plant is propagated by Off-ſets taken from the old Roots at the Time of tranſplanting them; which muſt be managed as hath been directed for the old Roots. The Flowers of this Plant are produced in *Auguſt* and *September*; but it ſeldom perfects Seeds in *England*.

HYACINTHUS TUBEROSUS.

The *Characters* are;

It hath a tuberoſe Root: The Stalk is erect, and ſurrounded with a leafy Covering by Intervals: The Flowers are large, and of a Lily-*ſhape, being much longer and larger than thoſe of the Bulbous* Hyacinths.

The *Species* are;

1. HYACINTHUS *Indicus tuberoſus, flore Hyacinthi orientalis. C. B. P.* The *Indian* Tuberoſe-rooted Hyacinth, *commonly call'd,* The Tuberoſe.
2. HYACINTHUS *Indicus tuberoſus, flore pleno. Boerh. Ind. alt.* The *Indian* Tuberoſe-rooted Hyacinth, with a double Flower, *commonly call'd,* The Double Tuberoſe.

The firſt of theſe Plants is very common in moſt Parts of *Europe:* The Roots of this Sort are generally brought from *Genoa* in great Plenty every Spring, by the Perſons that bring over *Orange trees* for Sale. But the ſecond Sort is very rare, and at preſent only in the Gardens of ſome curious Perſons, who have been favour'd with the Roots by Monſ. *de la Court* near *Leyden* in *Holland*, who obtain'd it from Seeds of the ſingle Kind ſome Years ſince. This Curioſity was for many Years kept as a Rarity by the Gentleman that rais'd it from Seeds, who refuſed to part with it 'till of late, tho' he had ſuch Plenty of the Roots, as to deſtroy ſome Hundreds before he would part with any of them.

Theſe Plants are propagated by Off-ſets taken from the old Roots, which ſend them forth in great Plenty; but as they require to be ſhelter'd from the Cold of our Winters, ſo this Method is ſeldom practiſed in *England*, becauſe we can be furniſhed with freſh ſtrong Roots annually from Abroad at a very cheap Rate: I ſhall therefore proceed to the Culture of thoſe Roots which are brought over.

The Roots of this Plant generally arrive here in *February*, which is full early enough to plant them for the firſt Seaſon: But in order to continue a Succeſſion of their Flowers, they ſhould be planted at three different Times: The firſt, at the latter End of *February*, or the Beginning of *March*; theſe will flower at the latter End of *May*, or Beginning of *June*. The ſecond ſhould be planted the Beginning of *April:* Theſe will flower in *July*. The third ſhould be planted in the Beginning of *May*, which will flower in *Auguſt* or *September*, and ſome of them will continue 'till *October*. By which Method we may continue this fragrant Flower for four or five Months in Beauty.

When you are provided with the Roots, you muſt prepare a moderate Hot-bed, upon which ſhould be placed a Parcel of ſmall Flower-Pots, fill'd with freſh, light, rich Earth; then having taken off the Filth and decay'd Leaves, and Fibres of the Roots, as alſo the Off-ſets, (which, if permitted to remain upon the flowering Roots, will exhauſt much of their Nouriſhment, and cauſe 'em to blow very weak) you muſt plant the Roots one into each ſeparate Pot, obſerving that the Bud or Upper Part of the Root is but juſt cover'd with the Earth; for if they are buried too deep, they will ſometimes miſcarry.

Theſe ſhould have but little Water until they apppear abo Ground, but afterwards they require frequently to be refreſhed therewith: And as the green Leaves advance, ſo you mu be careful to give them Air, in Proportion to the Heat of th Weather, and the Bed in which they are planted; for if they are forc'd too faſt, it will cauſe their Flower-ſtems to run u very weak and tall; but the Flowers will be fewer in Number, and much ſmaller, than when they are brought up hardier. As the Stems advance, ſo you muſt raiſe your Coverings, and increaſe the Proportion of free Air; and in the Middle of *May* a ſlight Covering with Mats will be ſufficient; for then you muſt harden them by Degrees to bear the open Air. When the Flowers begin to open, the Pots ſhould be removed int Shelter; for if they are permitted to continue abroad, the We will ſoon deface the Flowers: But if they are ſkreen'd fro Wet, and the violent Heat of the Sun, they will continue i Beauty a long Time.

Thoſe Roots which are planted later in the Seaſon *will require* a leſs Degree of Heat; ſo that if the Hot-*bed does bu* bring them well up above-ground, the Heat of the Sun will b ſufficient for them afterwards, provided the Seaſon be not ver cold and wet; for if it ſhould happen to prove ſo, you mu add freſh Warmth to the old Bed, or remove the Pots to a new one to bring them forward, otherwiſe they will not flower tha Seaſon.

The double-flower'd Sort being propagated by Off-ſets, ſhall ſet down the Method uſed by Monſ. *de la Court*, as obſerv'd when I was at *Leyden*. In the Spring he takes up th old Roots before they begin to ſhoot, from which he takes o all the Off-ſets; then he plants the ſtrong Roots in the Manner above directed for the ſingle Sort: But the Off-ſets h plants about four Inches aſunder, upon a freſh Hot-bed covere over with very rich Earth; this Bed is arched over with Hoops and cloſely cover'd with Canvas and Mats, which are continued on during the Spring Months while the Weather is cold But as the Summer advances, ſo the Coverings are remov'd and the Plants ſuffered to enjoy the free open Air until th Autumn following, that the Nights begin to be cold, when h covers them, as before, until the Leaves are quite wither'd of at which Time he takes up ſome of them, and preſerves th Roots in dry Sand in the Green-houſe: But others he ſuffe to continue in the Beds until the ſucceeding Spring, obſerving to cover them, to preſerve the Roots from Froſts; which if they are not well ſecured from, as alſo from too much Wet, will entirely deſtroy them.

By this Management, I obſerved ſome Hundreds of Roots of this Plant, in the Gentleman's Garden above-mention'd, which were in flower, and a large Quantity of younger Roots, which were for the ſucceeding Year: So that by having a Succeſſion of Roots, he always has a ſufficient Number to flower every Year; for the Off-ſets will be two Years before they flower, and the old Roots will not flower again 'till the third Year.

HYDROCOTYLE, [of ὕδωρ, *Water*, and κότυλη, *a Cavity*; becauſe this Plant has a Cavity in the Leaves, and grows in Marſhes] Water Navelwort.

This Plant grows in great Plenty in moiſt Places in moſt Parts of *England*, and is never cultivated for Uſe, ſo I ſhall paſs it over with only naming it.

HYDROLAPATHUM. *Vide* Lapathum.

HYDROPHYLLON, Water-Leaf.

The *Characters* are;

It hath a bell-ſhaped Flower conſiſting of one Leaf, and cut into ſeveral Segments; from the Bottom-part of the Flower ariſes the Pointal, which afterward becomes a Fruit, opening in two Parts, incloſing Seeds of the ſame Shape as the Veſſel.

We have but one Sort of this Plant, *viz.*

HYDROPHILLON *Morini. Joncq. Hort.* Water-Leaf of *Morinus.*

This Plant is very hardy in reſpect to Cold, but it ſhould be planted in a moiſt rich Soil; if it is planted in a dry warm Soil, it will not live, unleſs it is conſtantly watered in dry Weather. It may be propagated by parting of the Roots, which ſhould be done in Autumn, that the Plants may be well rooted before Spring; for otherwiſe they will require a great deal of Water to preſerve them. The Roots ſhould not be parted too ſmall, nor ſhould it be done every Year, for that will weaken them too much; they will thrive very well in a ſhady Situation, provided it is not under the Drip of Trees. It flowers in *June*, but doth not perfect Seeds in this Country.

HYDROPIPER, the common biting Arſe-ſmart, which grows in great Plenty in moiſt Places near Ditches Sides almoſt every-where.

HYDROSTATICKS, [ὑδροστατικὴ, of ὕδωρ, *Water*, and στατικὴ, f στατὸς, *ſtanding*, of ἵστημι, *I ſtand* or *ſtop*; *Hydroſtaticks* being conceiv'd as the Doctrine of the Equilibrium of Liquors] s the Doctrine of the Gravitation of Fluids; or it is that Part f the Mechanicks which conſiders the Weight or Gravity of luid Bodies, particularly of Water, and of ſolid Bodies immerg'd therein.

To *Hydroſtaticks* belong whatever relates to the Gravities and Equilibria of Liquors; with the Art of weighing Bodies in Water, in order to eſtimate the ſpecifick Gravities.

Of the Uſe of this Science in *Horticulture*, the Reverend Dr. *Hale*, in his excellent Treatiſe of *Vegetable Staticks*, has given many Examples, by Experiments, ſhewing the Quantities of Moiſture imbib'd and perſpir'd by Plants and Trees, neceſſary to be known, in order to promote the Buſineſs of Vegetation.

Some of the moſt uſeful Heads of this Science, are;

1. That the upper Parts of all Fluids preſs upon the lower.

2. That a lighter Fluid may gravitate or preſs upon a heavier.

3. That if a Body that is contiguous to the Water, be altogether or in part lower than the upper Surface of the Water, e lower Part of the Body will be preſs'd upwards by the Water which touches it beneath.

4. There needs only a competent Weight of an external luid to account for the riſing of Water in Pumps, *&c.*

5. If a Body be placed under Water, ſo that its uppermoſt urface lie parallel to the Horizon, the direct Preſſure that it ſtains is no more than that of a Column of Water, whoſe aſe is the horizontal Superficies of the Body, and its Height e perpendicular Depth of the Water. And if the Water hich leans on the Body be contain'd in Pipes, which are open both Ends, the Preſſure of the Water is to be eſtimated by e Weight of a Pillar of Water, the Baſe of which is equal the lower Orifice of the Pipe, and whoſe Height is equal to a Perpendicular which reaches from thence to the Top of the Water, altho' the Pipe ſhould be much inclined any Way, or tho' it ſhould be ever ſo irregularly ſhaped, and much broader in ſome other Place than the Bottom.

6. A Body which is immers'd in a Fluid, ſuſtains a natural Preſſure from the Fluid, which alſo increaſes as the Body is placed deeper beneath the Surface of the Fluid.

7. The Reaſon why Water aſcends in Syphons, and by which it flows thro' them, may be explain'd from the external Preſſure of ſome other Fluid, without having recourſe to the Abhorrence of a Vacuum.

8. The moſt ſolid Body, which will ſink by its own Weight at the Surface; yet, if it be placed at a Depth twenty times greater than that of its own Thickneſs, it will not ſink, if its Deſcent be not aſſiſted by the incumbent Water.

9. If a Body which is ſpecifically lighter than a Fluid, be immers'd in that Fluid, it will riſe with a Force proportionable to the Exceſs of Gravity in that Fluid.

10. If a Body which is heavier than a Fluid be immers'd, it will ſink with a Force that is proportionable to the Exceſs of its Gravity.

11. If any Veſſel be fill'd with Water, or any other Liquor, the Surface of which is capable of being even, it will continue ſo till diſturbed by ſome other external Cauſe.

12. When the Fluids are preſs'd, they are preſs'd *undequaque*, i. e. on all Sides.

How far the Knowledge of any of theſe Properties of *Fluids* may conduce to the Philoſophical Improvement of *Gardening*, and the Buſineſs of *Vegetation*, will be more clearly perceiv'd, when well conſider'd by the ingenious Artiſt, than being ſet forth by Words.

HYGROMETER, [ὑγρόμετρον, of ὕγρος *moiſt*, and μέτρον *meaſure*, of μετρέω *to meaſure*] is a Machine or Inſtrument contriv'd to ſhew or meaſure the Moiſtneſs and Dryneſs of the Air, according as it abounds with moiſt or dry Vapours, and to meaſure and eſtimate the Quantity of ſuch Moiſtneſs and Dryneſs.

There are divers Kinds of *Hygrometers*; for whatever Body either ſwells or ſhrinks by Dryneſs or Moiſture, is capable of being form'd into an *Hygrometer*; ſuch are Woods of moſt Kinds, particularly *Aſh*, *Deal*, *Poplar*, &c. ſuch alſo is a *Cord*, *Cat-gut*, &c.

Stretch a Hempen-cord or *Fiddle-ſtring* along a Wall, bringing it over a Truckle or Pulley, and to the other End tie a Weight, unto which fit a Style or Index; on the ſame Wall fit a Plate of Metal divided into any Number of equal Parts, and the *Hygrometer* is compleat.

For it is a Matter of undoubted Obſervation, that Moiſture ſenſibly ſhortens the Length of Cords and Strings; and that as the Moiſture evaporates, they return to their former Length: And the like may be ſaid of a Fiddle-ſtring.

The Weight therefore, in the preſent Caſe, upon an Increaſe of the Moiſture of the Air, will aſcend; and upon a Diminution of the ſame, will deſcend.

Hence, as the Index will ſhew the Spaces of Aſcent and Deſcent, and thoſe Spaces are equal to the Increments and Decrements of the Length of the Cord or Gut, the Inſtrument will diſcover whether the Air be more or leſs humid now, than it was at another given Time.

The ordinary Contrivance with Whip-cord, is one of the eaſieſt; for that will infallibly ſhorten and lengthen as the Air grows moiſter and drier.

Some recommend a *Cat-gut* as the beſt, which may be a Yard in Length, ſuſpended, having a Plummet or Piece of Lead, with an Index or Pointer, hanging at the lower End, by means of which the *Cat-gut* will twiſt or untwiſt as the Air dries or moiſtens, and ſhorten and lengthen ſo as to raiſe and ſink the Plummet with the Index; and this Index will point out the Degree ſought for.

The Weight of this Lead or Plummet ſhould be about two Ounces.

Some Perſons who approve a fine Whip-cord inſtead of Catgut, uſe a greater Weight of Lead: The twiſting and untwiſting of the *Cat-gut* or *Whip-cord*, will make the Lead with the Index turn round, as well as riſe and fall: The Degrees may be made upon an open Screw of Braſs within, with which the Plummet and Index has its Motion.

When you are provided with a *Barometer* and *Hygrometer*, compare the Motions of the one with the other, in order to judge what Proportion the Riſe or Fall of the Quickſilver in the *Barometer* bears to the twiſting of the *Cat-gut* or *Whipcord*; the Degrees of which Motion may be obſerved by the Index or Pointer of the *Hygrometer*; and at the ſame time both theſe muſt be compared with the riſing and falling of the Spirit in a *Thermometer*, to know what Degree of *Heat* or *Cold* attends every different Change of Weather.

HYGROSCOPE, [of ὑγρος *moiſt*, and σκοπέω *to view or conſider*] a Machine the ſame as the *Hygrometer*, and for the ſame Uſes.

The Inſtruments are of good Uſe in Conſervatories for meaſuring or ſhewing the Dampneſs or Drineſs of them in the Winter-ſeaſon.

HYOSCYAMUS, [of ὗς *a Swine*, and κύαμος *a Bean*, q. d. *Hog's-bean.*] Hen-bane.

The *Characters* are;

The Leaves are ſoft and hairy, growing alternately upon the Branches: The Cup of the Flower is ſhort, and Bell-ſhaped, and divided into five Segments: The Flower conſiſts of one Leaf, the bottom Part of which is tubuloſe, but is expanded at the Top, and divided into five Segments, having five obtuſe Stamina: The Fruit, which is incloſed with the Calyx, reſembles a Pot with a Cover to it, and is divided, by an intermediate Partition, into two Cells, which contain many ſmall Seeds.

The *Species* are;

1. HYOSCYAMUS *vulgaris, vel niger. C. B. P.* Common Black Hen-bane.

2. HYOSCYAMUS *albus major, vel tertius Dioſcoridis, & quartus Plinii. C. B. P.* Greater White Hen-bane.

3. HYOSCYAMUS *major, albo ſimilis, umbilico floris atropurpureo. T. Cor.* Great Hen-bane like the White, but with a dark-purple Bottom to the Flower.

4. HYOSCYAMUS *minor, albo ſimilis, umbilico floris virenti. Jeſſieu.* Leſſer Hen-bane like the White, with a green Bottom to the Flower.

5. HYOSCYAMUS *rubello flore. G. B. P.* Hen-bane, with a reddiſh-colour'd Fruit.

6. HYOSCYAMUS *Creticus luteus major. C. B. P.* Great yellow Hen-bane of *Candia*.

There are ſeveral other Varieties of this Plant, which are preſerv'd in Botanick Gardens, to add to their Numbers of Plants; but ſince they are rarely cultivated for Uſe, ſo I ſhall forbear to ſay any thing of them in this Place.

The firſt of theſe Sorts is very common in *England*, growing upon the Sides of Banks and old Dunghills almoſt every where. This is a very poiſonous Plant, and ſhould be rooted out in all Places where Children are ſuffer'd to come; for in the Year 1729 there were three Children poiſon'd with eating the Seeds of this Plant, near *Tottenham-court*, two of which ſlept two Days and two Nights before they could be awaken'd, and were, with Difficulty recover'd; but the third, being older and ſtronger, eſcaped better.

The ſecond Sort is by moſt Authors ſuppoſed to be the true White *Hen-bane* of the Shops, the Seeds of which ſhould be uſed in Medicine; tho' there is very little Difference in the Seeds of that, and the third and fourth Sorts, either of which may probably do. The other Sorts are of no Uſe or Beauty: but whoever hath a Mind to cultivate any of theſe Plants, may ſow their Seeds in the Spring, upon a light, dry, undung'd Soil; and when the Plants are come up, they ſhould be tranſplanted out, allowing them two Feet Diſtance each way: The ſecond Summer they will produce Flowers and Seeds, and ſoon after the Roots periſh.

HYPECOON.

We have no *Engliſh* Name for this Plant.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in Form of a Croſs; theſe are uſually divided into three Parts: Out of the Flower-cup riſes the Pointal, which afterward becomes a plain ſmooth, jointed Pod, full of kidney-ſhaped Seeds, which are incloſed in each Joint.

The *Species* are;

1. HYPECOON *latiore folio. Tourn.* Broad-leav'd Hypecoon.

2. HYPECOON *tenuiore folio. Tourn.* Narrow-leav'd Hypecoon.

3. HYPECOON *Orientale, latiore folio, flore magno. Tourn. Cor. Eaſtern* Hypecoon, with a broader Leaf, and a large Flower.

4. HYPECOON *Orientale, fumariæ folio. Tourn. Cor. Eaſtern* Hypecoon, with a fumitary Leaf.

The firſt and ſecond Sorts grow plentifully in the South of *France*, in *Spain* and *Italy*; but the third and fourth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*; from whence he ſent their Seeds to the *Royal Garden* at *Paris*.

Theſe Plants are all of them annual, ſo their Seeds ſhould be ſown the Beginning of *March*, on a Bed of light freſh Earth, where they are to remain; for they ſeldom ſucceed if they are tranſplanted. When the Plants are come up, they ſhould be carefully cleared from Weeds; and where the Plants are too cloſe, they muſt be thinned, leaving them about ſix or eight Inches apart; after this they will require no other Culture, but to keep them conſtantly clear from Weeds. In *June* theſe Plants will flower, and their Seeds will be ripe in *Auguſt*.

Sometimes, when the Spring proves very dry, the Seeds will not grow the firſt Year; but if the Ground is kept clear from Weeds, and not diſturbed, the Plants will come up the following Spring. I have known the Seeds of theſe Plants remain in the Ground two Years, and the Plants have come up the third Spring very well; ſo that it may be very proper to ſow ſome of their Seeds in Autumn, ſoon after they are ripe, in a warm Border, where the Plants may come up early the following Spring; and theſe will be ſtronger, and more likely to perfect Seeds, than thoſe ſown in the Spring; by which Method the Kinds may be preſerved.

Theſe Plants are ſeldom propagated but by thoſe who are curious in Botany, tho' for the ſake of Variety they may have a Place in large Gardens, becauſe they require very little Trouble to cultivate them; and as they take up but little Room, ſo they may be intermixed with other ſmall annual Plants in large Borders, where they will make a pretty Appearance.

The Juice of theſe Plants is of a yellow Colour, reſembling that of *Celandine*; and is affirmed by ſome eminent Phyſicians, to have the ſame Effect as *Opium*.

HYPERICUM, [ὑπερικῶν, q. d. an *Herb*, the Image of which is Eminent; or becauſe it has reſpect to, or beholds the Sun.] St. John's-wort.

The *Characters* are;

It hath a fibroſe Root: The Leaves grow oppoſite by Pairs a the Joints of the Stalks: The Flower-cup conſiſts of one Leaf which it divided into five Parts, and expanded: The Flower which conſiſts of five Leaves, expands in form of a Roſe, *havin many Stamina in the Center ſurrounding a conical Ovary, whic becomes a three-corner'd pointed Fruit, and is divided into thr Cells containing many ſmall Seeds.*

The *Species* are;

1. HYPERICUM *vulgare. C. B. P.* Common St. John's wort.

2. HYPERICUM *Aſcyron dictum, caule quadrangulo. J. B* St. John's-wort, with a ſquare Stalk, *commonly call'd* St. Peter's wort.

3. HYPERICUM *fœtidum fruteſcens. Tourn.* Stinkin ſhrubby St. John's-wort.

4. HYPERICUM *fruteſcens Canarienſe multiflorum. Hor Amſt.* Shrubby St. John's-wort from the *Canaries*, wit many Flowers.

5. HYPERICUM *Orientale, flore magno. T. Cor. Eaſte* St. John's-wort, with a large Flower.

6. HYPERICUM *villoſum erectum, caule rotundo. Tour* Upright hairy St. John's-wort, with a round Stalk.

7. HYPERICUM *elegantiſſimum non ramoſum, folio lat J. B.* The moſt beautiful St. John's-wort without Branche and a broad Leaf.

8. HYPERICUM *minus erectum. C. B. P.* Small uprig St. John's-wort.

9. HYPERICUM *minus ſupinum, vel ſupinum glabrum. C B. P.* Small ſmooth trailing St. John's-wort.

10. HYPERICUM *folio breviore. C. B. P.* Short-leav'd S John's-wort.

11. HYPERICUM *criſpum, triquetro & cuſpidato folio. Boc Muſ.* Curled St. John's-wort, with a three-corner'd an pointed Leaf.

12. HYPERICUM *perfoliatum & perforatum. Tourn.* Pe foliate and perforated St. John's-wort.

13. HYPERICUM *amplo perfoliato folio. Tourn.* St. John' wort, with a large thorough-wax Leaf.

14. HYPERICUM *Alpinum humilius, magno flore puncta Tourn.* Dwarf St. John's-wort of the *Alps*, with a lar ſpotted Flower.

15. HYPERICUM *latifolium Luſitanicum. Tourn.* Broa leav'd *Portugueſe* St. John's-wort.

16. HYPERICUM *Luſitanicum, linariæ folio. Tourn. Po tugueſe* St. John's-wort, with a toad-flax Leaf.

17. **Hypericum** *tomentoſum Luſitanicum minimum. Tourn.* The ſmalleſt woolly *Portugueſe* St. John's-wort.

18. **Hypericum** *Creticum ſupinum, folio ſubrotundo, flore magno. Tourn. Cor. Candy* trailing St. John's-wort, with a roundiſh Leaf, and a large Flower.

19. **Hypericum** *Creticum, ampliſſimo folio nitido. Tourn. Cor. Candy* St. John's-wort, with a large ſhining Leaf.

20. **Hypericum** *villoſum, foliis caulem ambientibus acutis, cæteris vero circinatis. Tourn. Cor.* Hairy St. John's-wort, with pointed Leaves encompaſſing the Stalk, and the bottom Leaves exactly round.

21. **Hypericum** *Orientale, foliis ſubrotundis auritis, cauli adhærentibus. Tourn. Cor. Eaſtern* St. John's-wort, with roundiſh-eared Leaves adhering to the Stalk.

22. **Hypericum** *Orientale, ptarmicæ foliis. Tourn. Cor. Eaſtern* St. John's-wort, with ſneezwort Leaves.

23. **Hypericum** *Orientale, fœtido ſimile, ſed inodorum. Tourn. Cor. Eaſtern* St. John's-wort, like the ſtinking Kind, but without Smell.

24. **Hypericum** *Orientale ſaxatile, majoranæ folio. Tourn. Cor. Eaſtern* rock St. John's-wort, with a Marjoram Leaf.

25. **Hypericum** *Orientale, androſæmo hirſuto ſimile, ſed glabrum. Tourn. Cor. Eaſtern* St. John's-wort, reſembling hairy Tutſan, but ſmooth.

26. **Hypericum** *Orientale, polygoni folio. Tourn. Cor. Eaſtern* St. John's-wort, with a knot-graſs Leaf.

27. **Hypericum** *Orientale, caule aſpero purpureo. Tourn. Cor. Eaſtern* St. John's-wort, with a rough purple Stalk.

28. **Hypericum** *Orientale, caule aſpero purpureo, linariæ folio. Tourn. Cor. Eaſtern* St. John's-wort, with a rough purple Stalk, and a toad-flax Leaf.

29. **Hypericum** *Orientale, roriſmarini folio glauco. Tourn. Cor. Eaſtern* St. John's-wort, with a ſea-green roſemary Leaf.

30. **Hypericum** *Orientale latifolium ſubhirſutum, caule purpureo villoſo. Tourn. Cor.* Broad-leav'd *Eaſtern* St. John's-wort, ſomewhat hairy, with a purple hairy Stalk.

The firſt and ſecond Sorts are both very common Plants, growing in the Fields in moſt Parts of *England*; the firſt is uſed in Medicine, but the ſecond is of no Uſe: Theſe are rarely propagated in Gardens; but I chuſe to mention them, in order to introduce the other Sorts, which deſerve a Place in every good Garden.

The third and fourth Sorts are ſhrubby Plants, which are very proper to intermix with other flowering Shrubs of the ſame Growths, where, by their long Continuance in Flower, they will make a very handſome Appearance. The third Sort is of an humble Stature, ſeldom riſing above four Feet in Height; but the fourth will grow to the Height of ſeven or eight Feet.

Theſe two Sorts are propagated by Suckers, which are plentifully ſent forth from the old Plants. The beſt Seaſon for taking off theſe Suckers is in *March*, juſt before they begin to ſhoot: They ſhould be planted in a light dry Soil, in which they will endure the ſevereſt Cold of our Climate very well. They may alſo be propagated by Cuttings, which ſhould be planted at the ſame Seaſon; or by Seeds, which muſt be ſown in *Auguſt* or *September*, which is as ſoon as they're ripe; for if they are kept till Spring, few of them will grow: but as they multiply ſo faſt by Suckers, the other Methods of propagating them are ſeldom practiſed in *England*.

The only Care theſe Shrubs require, is, to clear them from Suckers every Spring, and to cut out all decay'd and luxuriant Branches, in order to reduce them to a regular Figure: They produce their Flowers in *July*, and continue flowering until the End of *September*, which renders them very agreeable; but their Leaves, when bruiſed, do emit a very rank Odour.

The Eaſtern Sort is alſo an abiding Plant, but it ſeldom riſes above eighteen Inches, or two Feet high: This is propagated by parting the Roots, and planting Cuttings in the Spring; it is ſomewhat tenderer than the laſt, but will endure the Cold of our ordinary Winters in the open Air, provided it be not too much expoſed to the cold Winds: It may alſo be propagated by ſowing the Seeds in *March* upon a Bed of light Earth, in an open Situation; and when the Plants are large enough to be tranſplanted, they may be placed in the warm Borders of the Pleaſure-garden, and the Summer following they will produce their Flowers in large Quantities upon the Tops of the Branches; which being of a large Size, and a bright-yellow Colour, do make a very handſome Shew.

The ſixth, ſeventh, eighth and ninth Sorts are Natives of *England*, growing in Woods and other ſhady Places in divers Parts. The tenth, eleventh, twelfth and thirteenth Sorts grow in the South of *France*, *Italy*, and *Spain*; yet are hardy enough to endure the Cold of our ordinary Winters very well in the open Air. The fourteenth Sort grows on the *Alps*; the fifteenth, ſixteenth, and ſeventeenth Sorts are Natives of *Portugal*; but all the following Sorts were diſcovered by Dr. *Tournefort* in the *Levant*.

All theſe Plants may be propagated by ſowing of their Seeds ſoon after they are ripe, on a Bed of freſh undunged Earth; and when the Plants are come up, they ſhould be kept clear from Weeds; the following Spring they may be tranſplanted to the Places where they are to remain; after the Plants have taken new Root, they will require no farther Care, but to keep them clear from large Weeds, which, if ſuffered to grow amongſt them, will over-bear and deſtroy them.

Moſt of the Kinds being Natives of Woods and ſhady Places, will grow very well under the Drip of Trees; ſo that they may be planted in large Wilderneſs Quarters, where they will thrive and make a pretty Variety. But it will be proper to keep a few Plants of each Kind in a ſhady Border, where, if they are permitted to ſhed their Seeds, they will produce a Supply of young Plants, whereby the Kinds may be preſerved: for as ſome of the Kinds do not continue above two or three Years, ſo, where there is not Care taken to have a conſtant Supply of young Plants, their Kinds will be loſt; for where the Shade of the Wilderneſs is very thick, the Seeds which fall there will not ſucceed; becauſe the Leaves of the Trees falling in Autumn, when the Seeds are ripe, cover the Ground; whereby the Seeds either do not reach the Earth, or if they do, they are ſo cloſely covered by the falling Leaves, that they cannot enjoy the Benefits of the Air; ſo that they rarely grow.

HYPERICUM FRUTEX. *Vide* Spirea.

HYPOCISTIS.

We have no *Engliſh* Name for this Plant.

The *Characters* are;

It hath a bell-ſhaped Flower conſiſting of one Leaf, which is cut into ſeveral Segments at the brim: the hinder Part of the Flower becomes a ſoft Fruit, divided into Rays, in which are contained the Seeds.

The *Species* are;

1. **Hypocistis** *Cretica, flore purpureo. Tourn. Cor. Candy* Hypociſtis, with a purple Flower.
2. **Hypocistis** *purpurea, flore candicante. Tourn. Cor.* Purple Hypociſtis, with a white Flower.
3. **Hypocistis** *flore luteo. Tourn. Cor.* Hypociſtis, with a yellow Flower.
4. **Hypocistis** *palleſcentis coloris, lineis purpuraſcentibus & nonnihil vireſcentibus diſtincta. Cluſ. Hiſt.* Pale-coloured Hypociſtis, with purpliſh Lines.

Theſe Plants grow from the Root of the *Ciſtus*, or *Rock-roſe*, ſo cannot be cultivated by Art; it being a Super-plant, like the *Miſleto*; and it is not known to grow on any other Plant but the *Ciſtus*. But as one of the Species is uſed in Medicine, I thought it proper to mention the ſeveral Kinds which have been diſcovered.

HYPOHYLLOSPERMOUS Plants, [of ὑπὸ *under*, φλύλον, *a Leaf*, and σπέρμα, *Seed*] are ſuch Plants as bear their Seeds on the Backſides of their Leaves.

HYSSOPUS [takes its Name from the *Hebrew* Word אזוב, in which Language *Hyſſop* ſignifies an holy Herb, or for purging or cleanſing ſacred Places; as it is ſaid in the *Pſalms*, *Purge me with Hyſſop*. But what Plant the *Hyſſop* of the Ancients was, is not known; but that it ſeems to have been a low Plant, becauſe *Solomon* is ſaid to have deſcribed the Plants from the *Cedar* to the *Hyſſop*] Hyſſop.

The *Characters* are;

It is a verticillate Plant, with long narrow Leaves: The Galea (or Creſt) of the Flower is roundiſh, erect, and divided into two Parts: The Barba (or Beard) is divided into three Parts; the middle Part is hollow'd like a Spoon, having a double Point, and is ſomewhat winged: The Whorles of the Flowers are ſhort, and at the Lower-part of the Stalk are placed at a great Diſtance, but towards the Top are cloſer join'd, ſo as to form a regular Spike.

The *Species* are;

1. Hyssopus *officinarum cærulea, ſeu ſpicata.* *C. B. P.* Common *Hyſſop* of the Shops, with blue Flowers growing in a Spike.

2. Hyssopus *vulgaris alba.* *C. B. P.* Common *Hyſſop*, with a white Flower.

3. Hyssopus *rubro flore.* *C. B. P.* *Hyſſop*, with a red Flower.

4. Hyssopus *montana Macedonica, Valerandi Dourez.* *J. B.* Mountain Macedonian *Hyſſop*.

5. Hyssopus *humilior myrtifolia.* *H. R. Par.* Dwarf Myrtle-leaf'd *Hyſſop*.

6. Hissopus *utrinque florida.* *Dod. pempt.* Hyſſop bearing Flowers on every Side.

7. Hyssopus *vulgaris, moſchum redolens.* *C. B. P.* Common *Hyſſop*, ſmelling like Muſk.

8. Hyssopus *criſpa.* *Geſner. Hort.* Curled *Hyſſop*.

9. Hyssopus *foliis diſſectis.* *C. B. P.* *Hyſſop* with cut Leaves.

10. Hyssopus *ſpica brevi & rotunda.* *C. B. P.* *Hyſſop*, with a ſhort and round Spike.

11. Hyssopus *verſicolor ſive aureus.* *Park. Par.* Gold-ſtriped *Hyſſop*.

12. Hyssopus *hirſuta.* *C. B. P.* Hairy *Hyſſop*.

13. Hyssopus *hirſuta, flore albo.* *Tourn.* Hairy *Hyſſop*, with a white Flower.

The firſt five Sorts of *Hyſſop* are propagated either by Seeds or Cuttings: If by the Seeds, they muſt be ſown in *March* upon a Bed of light ſandy Soil; and when the Plants are come up, they ſhould be tranſplanted out to the Places where they are to remain, placing them at leaſt a Foot aſunder each way: But if they are deſigned to abide in thoſe Places for a long time, two Feet Diſtance will be ſmall enough; for they grow pretty large, eſpecially if they are not frequently cut, to keep them within compaſs: They thrive beſt upon a poor dry Soil, in which Situation they will endure the Cold of our Climate better than when they are planted on a richer Soil. If you you would propagare them by Cuttings, they ſhould be planted in *April* or *May*, in a Border where they may be defended from the violent Heat of the Snn; and being frequently water'd, they will take Root in about two Months; after which, they may be tranſplanted where they are to continue, managing them as was before directed for the Seedling Plants.

The firſt Sort was formerly more cultivated than at preſent in *England*, that being the Sort commonly uſed in Medicine. The other Species are preſerved in curious Gardens for their Variety, but they are ſeldom cultivated for Uſe.

It hath been a great Diſpute amongſt modern Writers, whether the *Hyſſop* now commonly known, is the ſame which is mention'd in Scripture: About which there is great room to doubt; there being very little Grounds to aſcertain that Plant: tho' it is moſt generally thought to be the *Winter-Savory*, which Plant is now in great Requeſt amongſt the Inhabitants of the Eaſtern Countries, for Outward Waſhings or Purification.

The other Sorts of *Hyſſop* are very hardy Plants, which will endure the Cold of our Winters in the open Air, provided they are planted in a dry undunged Soil; for when they are planted in a rich Soil, they grow very luxuriant in Summer, and are leſs able to reſiſt the Cold in Winter: ſo that when any of theſe Plants grow out of the Joints of old Walls, (as they frequently do) they will reſiſt the moſt ſevere Froſt; and theſe Plants will be much more aromatic, than thoſe which grow in a rich Soil.

They may be propagated by ſowing of their Seeds in the Spring, in the Manner which is directed for the common Sort, with which Management all theſe Sorts will agree except the ſtriped Kind, which is no way propagated but by Slips, which ſhould be planted the Beginning of *March*, on a Border of freſh undunged Earth, obſerving in dry Weather to water them until they have taken Root; after which time they muſt be kept clear from Weeds, and at *Michaelmas* the Plants ſhould be tranſplanted where they are to remain, which ſhould be on a dry, ſtony or gravelly Spot of Ground, where they will preſerve the Beauty of their variegated Leaves much better than in a good Soil.

J A

JACEA, [of *Jacere*, Lat. *to lie along*; becauſe this Plant often lies on the Ground] Knap-weed.

The *Characters* are;

It is one of the Herbæ Capitatæ *(or Headed Plants) which is deſtitute of Spines: The Calyx (or Cup) is ſquamoſe: The Borders of the Leaves are commonly equal, being neither ſerrated nor indented: The Florets round the Border of the Head are barren; but thoſe placed in the Centre are ſucceeded each by one Seed, having a Down adhering to it.*

The *Species* are;

1. Jacea *nigra pratenſis latifolia.* *C. B. P.* Broad-leav'd Meadow Black Knap-weed.

2. Jacea, *cum ſquamis pennatis, ſive capite villoſo.* *J. B.* Woolly-headed Knap-weed.

3. Jacea *montana candidiſſima, ſtœbes foliis.* *C. B. P.* Mountain Knap-weed, with very white Leaves.

4. Jacea *Luſitanica ſempervirens.* *H. R. Par.* Portugal Ever-green Knap-weed.

5. Jacea *Epidaurica, candidiſſima & tomentoſa.* *Tourn.* White woolly Knap-weed of *Raguſa*.

6. Jacea *cyanoides, echinato capite.* *C. B. P.* Prickly-headed Knap-weed.

7. Jacea *nigra pratenſis latifolia, flore albo.* *Tourn.* Broad-leav'd Meadow Knap-weed, with a white Flower.

8. Jacea *nigra pratenſis anguſtifolia.* Narrow-leav'd Meadow Knap-weed.

9. Jacea *cum ſquamis cilii inſtar piloſis.* *J. B.* Knap-weed with hairy Scales.

10. Jacea *nigra, ſquamoſo capite, major.* *C. B. P.* Greater Black Knap-weed, with a ſcaly Head.

11. Jacea *nigra, ſquamoſo capite, minor.* *C. B. P.* Smaller Black Knap-weed, with a ſcaly Head.

12. Jacea *vulgaris laciniata, flore purpureo.* *Tourn.* Great Knap-weed, or Matfellon.

13. Jacea *vulgaris laciniata, flore albo.* *Tourn.* Great Knap-weed, or Matfellon with a white Flower.

14. Jacea *latiſſimo laciniato folio.* *C. B. P.* Knap-weed with a broad jagged Leaf.

15. Jacea *cinerea laciniata, flore purpureo.* *Triumf.* Jagged aſh-coloured Knap-weed, with a purple Flower.

16. Jacea *foliis cichoraceis villoſis, altiſſima, flore purpureo.* *Tourn.* The talleſt Knap-weed, with hairy ſuccory Leaves, and a purple Flower.

17. Jacea *foliis cichoraceis villoſis, altiſſima, flore albo.* *Tourn.* The talleſt Knap-weed, with hairy ſuccory Leaves, and a white Flower.

18. Jacea *foliis erucæ lanuginoſis.* *Tourn.* Knap-weed with woolly Rocket-leaves.

19. Jacea *foliis candicantibus laciniatis, calyculis non ſplendentibus.* *Tourn.* Knap-weed with whitiſh jagged Leaves, and Empalement not ſhining.

20. Jacea *foliis laciniatis viridibus, calyculis argenteis.* *Tourn.* Knap-weed with green jagged Leaves, and ſilver Empalements.

21. Jacea *calyculis argenteis, minor.* *Tourn.* Leſſer Knap-weed, with ſilver Empalements.

22. Jacea *Alpina, ſucciſæ folio.* *Tourn.* Mountain Knap-weed, with a devils-bit Leaf.

23. Jacea *folio cerinthes, è Rupe Victoriæ.* *Tourn.* Knap-weed, with a honey-wort Leaf.

24. Jacea *Hiſpanica latifolia, nervis foliorum lanuginoſis.* *Bocc. Muſ.* Broad-leav'd Spaniſh Knap-weed, with the Nerves of the Leaves woolly.

25. Jacea *Cretica aculeata incana.* *Tourn.* Hoary prickly Knap-weed of *Crete*.

26. Jacea *tomentoſa, foliis undulatis.* *Tourn.* Woolly Knap-weed, with waved Leaves.

27. Jacea *Cretica ſaxatilis, glaſti folio.* *Tourn. Cor.* Rock Knap-weed of Candy, with a woad Leaf.

28. Jacea *Cretica laciniata argentea, parvo flore flaveſcente.* *Tourn. Cor.* Silver jagged Candy Knap-weed, with a ſmall yellowiſh Flower.

29. Jacea *Cretica acaulos, cichorii folio.* *Tourn. Cor.* Candy Knap-weed, without a Stalk, and a ſuccory Leaf.

30. Jacea *orientalis acaulos, cichorii folio, flore citrino.* *Tourn. Cor.* Eaſtern Knap-weed, without a Stalk, and a citron-coloured Flower.

31. Jacea *orientalis patula, carthami facie, flore luteo magno. Tourn. Cor.* Spreading Eaſtern Knap-weed, with the Face of Baſtard Saffron, and a large yellow Flower.

32. Jacea *orientalis, conyzæ folio, flore magno. Tourn. Cor.* Eaſtern Knap-weed, with a fleabane Leaf, and a large Flower.

33. Jacea *orientalis, cyani folio, flore parvo, calyce argenteo. Tourn. Cor.* Eaſtern Knap-weed, with a blue-bottle Leaf, and a ſmall Flower with a ſilver Empalement.

34. Jacea *orientalis, folio ſinuato ſubtus tomentoſo, flore purpureo. Tourn. Cor.* Eaſtern Knap-weed, with a ſinuated Leaf, hoary underneath, and a purple Flower.

35. Jacea *orientalis maritima incana, coronopi folio. Tourn. Cor.* Eaſtern maritime hoary Knap-weed, with a Bucks-horn Leaf.

36. Jacea *orientalis perennis, lato coronopi folio, flore purpuraſcente. Tourn. Cor.* Perennial *Eaſtern* Knap-weed, with a broad Bucks-horn Leaf, and a purpliſh Flower.

37. Jacea *orientalis perennis, anguſtiſſimo & incano coronopi folio, flore purpuraſcente. Tourn. Cor.* Perennial Eaſtern Knap-weed, with a very narrow and hoary Bucks-horn Leaf, and a purpliſh Flower.

38. Jacea *orientalis laciniata incana & moſchata. Tourn. Cor.* Hoary muſk jagged-leav'd Eaſtern Knap-weed.

39. Jacea *lutea-ſpinoſa centaurioides. C. B. P.* Prickly yellow Knap-weed, like the greater Centaury.

40. Jacea *latifolia purpurea, capitulo ſpinoſo. C. B. P.* Broad-leav'd purple Knap-weed, with a prickly Head.

41. Jacea *ſpinoſa Cretica, an ſpecies hyoſiridis Plinii. Zan.* Prickly Knap-weed of Candy, ſuppoſed to be a Species of Hyoſiris of Pliny.

42. Jacea *marina Bætica. Park. Theat.* Sea Spaniſh Knap-weed.

43. Jacea *cyanoides altera, caule alato. Par. Bat.* Another Knap-weed like Blue-bottle, with a winged Stalk.

44. Jacea *Melitenſis, capitulis conglobatis. Bocc. Rar. Plant.* Knap-weed of Malta, with conglobated Heads.

45. Jacea *orientalis annua, coronopi folio, flore luteo. Tourn. Cor.* Annual Eaſtern Knap-weed, with a Bucks-horn Leaf, and a yellow Flower.

46. Jacea *arboreſcens, ſtyracis folio. Tourn.* Tree-knapweed, with a ſtorax-tree Leaf.

47. Jacea *Cretica fruteſcens, elichryſi folio, flore magno purpuraſcente. Tourn. Cor.* Shrubby Knap-weed of Candy, with a goldylock Leaf, and a large purpliſh Flower.

48. Jacea *fruteſcens, plantaginis folio, flore albo. Tourn. Cor.* Shrubby Knap-weed, with a plantain Leaf, and a white Flower.

The firſt ſix are propagated by Seeds, which ſhould be ſown in *March* upon a Bed of light rich Earth; and when they are come up, they may be tranſplanted into a Nurſery-bed in ſome obſcure Part of the Garden, at about ten Inches or a Foot aſunder, where they may continue until the *Michaelmas* following, at which Time they may be tranſplanted into the Middle of large Borders in the Parterre Garden, where they may remain to flower: But the fifth Sort being tender, ſhould be planted into Pots, and ſhelter'd from great Froſts in Winter, which, if they are expoſed to, will deſtroy them. The ſixth Sort is an annual Plant, which ſhould be planted out in *May*, where it is deſigned to remain, and in *June* it will flower, and the Seeds will ripen in *Auguſt*. The firſt Sort is a Native of *England*, and is very common in Paſture Lands, eſpecially upon the Sides of Banks, or Foot-paths: This is ſeldom cultivated in Gardens.

Theſe Plants may deſerve a Place in large Gardens for Variety; but they are not proper for ſmall Gardens, their Branches taking up too much Room: And their Flowers having no great Beauty to recommend them, it is hardly worth excluding better Plants, to make Room for them.

The ſeventh Sort here mentioned, is a Variety of the common Kind, which differs in the Colour of the Flower; this is ſometimes found wild by the Sides of Hedges and Ditches, in low Paſture Ground.

The eighth Sort is very common by the Path-ſides in ſeveral Parts of *England*, ſo is rarely cultivated in Gardens.

The twelfth and thirteenth Sorts alſo grow wild in uncultivated Places in divers Parts of *England*, yet are worthy of a Place in large Gardens; for as they are laſting Plants, which require very little Care to cultivate them, and their Flowers being large and of long Continuance, ſo they will afford an agreeable Proſpect, in ſome ſhady abject Parts of the Garden, or under the Drip of Trees, where few better Plants will thrive.

The ninth, tenth, and eleventh Sorts, have been found wild in *England*, but theſe are leſs common than either of the former; but in *Holland* and *Flanders* they are very common. Theſe may alſo be allowed a Place in large Gardens for the ſake of Variety, becauſe they will thrive on the pooreſt Soil, and require no Trouble to cultivate them.

The fourteenth, fifteenth, ſixteenth, ſeventeenth, eighteenth, nineteenth, twentieth, twenty-firſt, twenty-ſecond, twenty-third, twenty-fourth, twenty-fifth and twenty-ſixth Sorts, are Natives of *France*, *Spain*, *Italy* and *Germany*; for which Countries they have been procured, and are preſerved in ſome curious botanick Gardens. Theſe, tho' ſome of them are Natives of warmer Countries, yet will live in the open Air in *England*, provided they are planted in a warm, dry, undunged Soil.

The thirty-ninth, fortieth, forty-firſt, and forty-ſecond Sorts, are all Natives of *Spain* and *Italy*; the thirty-ninth Sort, grows erect to the Height of three Feet, and on the Top of the Stalks are produced large yellow Flowers, which appear the Beginning of *June*, and continue in Beauty moſt part of *July*; ſo that it deſerves a Place in large Gardens, for the ſake of Variety. The fortieth, forty-firſt, and forty-ſecond Sorts, have large Heads and Flowers; which being heavy, and their Stalks but weak, they generally trail on the Ground, unleſs they are ſupported by Stakes. Theſe alſo produce a great Number of Branches, ſo that they require a large Share of Room, which renders them leſs valuable.

The twenty-ſeventh, twenty-eighth, twenty-ninth, thirtieth, thirty-firſt, thirty-ſecond, thirty-third, thirty-fourth, thirty-fifth, thirty-ſixth, thirty-ſeventh, and thirty-eighth Sorts, were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Seeds to the *Royal Garden* at *Paris*. Theſe Plants are ſomewhat more tender than the Sorts before mentioned; yet they will abide the Cold of our ordinary Winters very well in the open Air, provided they have a dry Soil, and a warm Situation.

Theſe Sorts may be propagated by Seeds, which ſhould be ſown in *March*, on a Bed of freſh undunged Earth, when the Plants begin to appear, they muſt be carefully cleared from Weeds; and as ſoon as they are fit to tranſplant, they ſhould be removed and planted in Beds of undunged Earth, at about a Foot Diſtance every Way. Theſe Plants muſt be watered, and if the Seaſon is hot, they ſhould be ſhaded until they have taken new Root; after which Time they will require no farther Care but to keep 'em clear from Weeds until *Michaelmas* following, when they ſhould be taken up and tranſplanted where they are deſigned to remain; the common hardy Sorts under Trees, in Wilderneſs Quarters, and other abject Parts of the Garden, where they will abide many Years, and only require to be kept clear from the largeſt Weeds, which will overbear them; but as for leſſer Weeds, they will not hurt them: the other Sorts, which are more tender, ſhould be planted in a warmer Situation, and on a lean ſtony Soil, where they will endure the Cold of our ordinary Winters very well, and afford an agreeable Variety.

The forty-third, forty-fourth, and fourty-fifth Sorts, are annual Plants. The Seeds of theſe muſt be ſown either in *March*, or the Beginning of *September*. Thoſe which are ſown in Autumn will come up, and the Plants will be ſtrong enough to reſiſt the Froſt, provided they are in a warm Border; and theſe Plants will flower much ſtronger, and come earlier in the Seaſon, than thoſe ſown in the Spring; ſo that theſe will always produce good Seeds. But if theſe autumnal Plants ſhould be deſtroyed by ſevere Froſt, then ſome of their Seeds ſhould be ſown in *March*, on a Bed of light freſh Earth, where they are deſigned to remain: For theſe Plants will not be large enough to tranſplant till *May*, when the Seaſon is generally warm; ſo that it will be difficult to make the Plants take Root, unleſs they are conſtantly ſhaded and watered: ſo it is the better Method to ſow theſe Seeds in the Spring on the Borders where they are to remain, and then all the Care required will be to clear them from Weeds, and thin the Plants where they come up too cloſe: But thoſe Plants which come up in Autumn, may be tranſplanted out the Beginning of *March*; at which Time they will ſoon take Root, and then will require no farther Culture but to keep them clear from Weeds. Theſe Plants continue a long Time in Flower, eſpecially the forty-third Sort; which renders them worthy of a Place in every large Garden.

The forty-ſixth, forty-ſeventh, and forty-eighth Sorts are ſhrubby Plants, which riſe to the Height of four or five Feet, and their Stems become woody. Theſe are Natives of the *Archipelago*, from whence their Seeds have been ſent to ſeveral curious botanick Gardens; but at preſent they are very rare in *England*. They may be propagated by ſowing of their Seeds in *March*, on a warm Border of freſh Earth; and when the Plants are come up, they muſt be carefully weeded, and in very dry Weather they ſhould be frequently refreſhed with Water. When the Plants have acquired Strength enough, they ſhould be carefully taken up, and each tranſplanted into a ſeparate ſmall Pot filled with freſh light Earth, and then placed in the Shade until they have taken new Root; when they may be removed into an open Situation, where they may remain till *October* following; during which Time they muſt be watered in dry Weather, and kept clear from Weeds; but in Winter they ſhould be ſheltered under a Hot-bed Frame, where they ſhould have as much free Air as poſſible in mild Weather, by taking off the Glaſſes every Day; but in hard Froſts they muſt be cloſely covered with Mats or Straw over the Glaſſes, to ſecure them from the Cold. The following Spring a few Plants of each Kind may be ſhaken out of the Pots, and planted in warm dry Borders, where they will live thro' the Winter, provided the Froſt is not very ſevere, and theſe Plants will flower much ſtronger than thoſe in Pots; but it will be proper to keep two Plants of each Kind in Pots to be ſheltered in Winter, for fear thoſe Abroad ſhould be deſtroyed, that the Kinds may be preſerved.

Theſe Plants ſeldom produce good Seeds in this Country, ſo that when the Plants are obtained, they may be propagated by Cuttings, which ſhould be planted about the Middle of *June* on a ſhady Border; where, if they are duly watered, they will take Root in about two Months; but it will be proper to let them remain in the ſame Border until the Beginning of *September*, when they ſhould be carefully taken up and planted into Pots, and placed in the Shade until they are rooted: Then they may be expoſed in an open Situation till the Middle or latter End of *October*, when they ſhould be removed into Shelter, and managed as hath been directed for thoſe Plants which are raiſed from Seeds. In Summer theſe Plants will flower, when they will afford an agreeable Proſpect, if they are placed among other hardy exotic Plants; and as they are evergreen, ſo they add to the Variety in Winter.

JACOBÆA, [ſo called of St. *James*, as ſays *Johannes Bauhinus*, becauſe it is ſaid to grow about the Chapel of St. *James* in *Spain*] Ragwort.

The *Characters* are;

It hath a radiated Flower, the Tube of which is almoſt of a cylindrical Figure, and the Seeds are faſten'd to Down: To which may be added, the Leaves are deeply laciniated, or jagged.

The *Species* are;

1. JACOBÆA *maritima. C. B. P.* Ragwort.
2. JACOBÆA *Africana fruteſcens, flore amplo purpureo, elegantiſſimo ſenecionis folio. Volk.* Shrubby African Ragwort, with an ample purple Flower, and Leaves like Groundſel.
3. JACOBÆA *Africana fruteſcens, foliis inciſis, & ſubtus cineraceis. Com. Rar.* African ſhrubby Ragwort, with cut Leaves, and the under Part of an Aſh Colour.
4. JACOBÆA *Africana fruteſcens, foliis abſinthii umbelliferi incanis. H. A.* Shrubby African Ragwort, with hoary Leaves like the umbellated Wormwood.
5. JACOBÆA *vulgaris laciniata. C. B. P.* Common Ragwort.
6. JACOBÆA *latifolia paluſtris, ſive aquatica. Raii Hiſt.* Broad-leav'd Marſh Ragwort.
7. JACOBÆA *Alpina, foliis ſubrotundis ſerratis. C. B. P.* Roundiſh ſawed-leav'd Ragwort of the *Alpes*.
8. JACOBÆA *Alpina, foliis longioribus ſerratis. Tourn.* Ragwort of the *Alpes*, with long ſaw'd Leaves.
9. JACOBÆA *montana, betonicæ folio. Barr. Icon.* Mountain Ragwort, with a betony Leaf.
10. JACOBÆA *chryſanthemi Cretici folio glauco. Tourn.* Ragwort with a ſea-green Chryſanthemum Leaf.
11. JACOBÆA *ſenecionis folio incano, perennis. Raii Hiſt.* Perennial hoary Ragwort, with groundſel Leaf.
12. JACOBÆA *Pannonica prima. Claſ. Hiſt.* Mountain Ragwort, with an undivided Leaf.
13. JACOBÆA *foliis amplioribus incanis. Mor. H. R. Blæſ.* Ragwort with large hoary Leaves.
14. JACOBÆA *maritima, ſive cineraria latifolia. C. B. P.* Broad-leav'd Sea Ragwort.
15. JACOBÆA *foliis ferulaceis, flore minore. Tourn.* Ragwort with fennel-giant Leaves and a ſmaller Flower.
16. JACOBÆA *foliis ferulaceis, flore majore. Tourn.* Ragwort with fennel-giant Leaves and a larger Flower.
17. JACOBÆA *Africana, botryos folio. Boerh. Ind. alt.* African Ragwort, with an Oak of *Jeruſalem* Leaf.
18. JACOBÆA *Chia, ſenecionis folio villoſo, flore magno. Tourn. Cor.* Ragwort of *Chio*, with a hoary groundſel Leaf, and a large Flower.
19. JACOBÆA *Orientalis, ſenecionis folio tenuiſſimè diviſo, non incano, flore magno. Tourn. Cor.* Eaſtern Ragwort, with a very narrow divided groundſel Leaf, not hoary, and a large Flower.
20. JACOBÆA *Græca maritima, foliis ſuperne virentibus, inferne incanis. Tourn. Cor. Greek* Sea Ragwort, with Leaves green on their upper Side, but hoary underneath.
21. JACOBÆA *Africana fruteſcens, abrotani folio. Oldenl.* Shrubby African Ragwort, with a ſouthernwood Leaf.
22. JACOBÆA *Africana abſinthii foliis. Oldenl.* African Ragwort, with Wormwood Leaves.
23. JACOBÆA *Americana odorata & viſcoſa, florum radiis breviſſimis albis. Houſt.* Sweet-ſmelling viſcous American Ragwort, with very ſhort white Rays to the Flower.

The firſt Sort was formerly nurs'd up with great Care, and preſerv'd in Winter amongſt *Oranges*, *Myrtles*, &c. in Green-houſes: But of late it has been tranſplanted into the open Air, where it is found to thrive exceeding well; and if planted in a dry Soil, and warm Situation, will very well endure the ſevereſt Cold of our Climate.

This Plant, tho' there is no great Beauty in its Flowers, yet, for the Oddneſs of its hoary, regular jagged Leaves, deſerves to have a Place in every good Garden.

The ſecond Sort is preſerved for the Beauty of its fine purple Flowers, which do continue a long Time; and growing in large Bunches, afford an agreeable Proſpect.

The third and fourth Sorts grow to the Height of five or ſix Feet, and will abide ſeveral Years, if carefully preſerv'd in Winter from extreme Cold: Theſe are commonly preſerved in the Green-houſe among other Exotick Plants, for their Variety.

Theſe Sorts may be propagated by Seeds, or Cuttings: But if you propagate them by Seeds, you ſhould ſow them in *March* upon a Bed of light Earth: Obſerving to water the Bed frequently in dry Weather, otherwiſe the Plants will not come up. About the Middle of *May*, if your Seeds ſhould ſucceed well, the Plants will be fit to tranſplant out; at which Time you ſhould put ſome of the three laſt Sorts into Po fill'd with light freſh Earth, ſetting them in the Shade unti they have taken Root; after which they may be expoſed in a open Situation until the latter End of *October*, when they mu be removed into Shelter. During the Winter-ſeaſon they mu be frequently water'd, without which they will ſoon decay and in Summer they muſt be often pruned, eſpecially the ſecon and third Sorts, to make them regular; otherwiſe they ar apt to be very rude and unſightly, for they grow very vigorouſly.

The ſecond Sort will produce Flowers and Seeds the fir Year, and is often treated as an annual Plant: But if it b houſed in the Winter, it will live very well for two Year They ſhould be renewed every Year or two at leaſt, otherwiſe they are ſubject to decay: The Cuttings whereof ma be planted in a ſhady Border in any of the Summer Months which, if carefully watered, will take Root in a Month' Time, whereby they may be greatly increaſed.

The *Sea Ragwort* may be alſo propagated by Cuttings o Slips, which muſt be planted and managed as the others; and when they are rooted, may be tranſplanted into a warm Situation, where they may continue to flower and ſeed. It is ver ſubject to degenerate when rais'd from Seeds, whereby th Whiteneſs, which is the greateſt Beauty of this Plant, i greatly diminiſhed, eſpecially upon the upper Parts of thei Leaves; ſo that the ſureſt Method is, to propagate it by Cuttings.

The fifth Sort is one of the moſt troubleſome Weeds, o poor wet Paſture Lands, and on Commons in almoſt ever Part of *England*; ſo is never admitted into Gardens, becau where the Seeds are permitted to ſcatter, the Down whic adheres to them, will carry them to a great Diſtance; ſo th all the Ground will be filled with the Weeds. The onl Method to deſtroy this Plant in Paſtures is, to go over th Land in *April*, when the Weather is dry, and with a Spaddl cut up the Plants by their Roots; and, if the Weather continues dry, they will ſoon dry up. This Work ſhould alſo b repeated in *Auguſt*, to cut up ſuch Plants as may have come u ſince *April*; and if this be repeated two or three Yea never ſuffering any of the Plants to ſtand to flower, it will e fectually deſtroy them.

The ſixth Sort is alſo a very common Weed on low marſ Lands, where the Water uſually ſtands in Winter. This alſo a very troubleſome Weed on many Commons, and oth Paſtures; but may be deſtroyed in the ſame Manner as t former.

Th

The ſeventh, eighth, and ninth Sorts are Natives of the *Alpes* and *Pyrenean* Mountains, from whence they have been procured, and are preſerved in ſeveral curious botanic Gardens, for the ſake of Variety. They may be propagated by Seeds, which ſhould be ſown in the Spring, on a Bed of freſh Earth; and when the Plants are come up, they ſhould be carefully weeded; and when they are ſtrong enough to be removed, they ſhould be tranſplanted into a ſtrong loamy Soil, where they will continue many Years and require no other Culture but to clear them from Weeds.

The tenth, twelfth, ſeventeenth, eighteenth, and nineteenth Sorts are annual Plants, which ſhould be ſown in the Spring, on a Bed of light freſh Earth, where they are deſigned to remain; and when the Plants come up, they ſhould be thinned where they are too cloſe, and kept clear from Weeds; which is all the Culture they require. In *June* they will flower, and their Seeds will ripen ſoon after; which, if permitted to ſcatter, will furniſh a Supply of young Plants where-ever the Seeds do fall.

The eleventh and twelfth Sorts grow wild in *England*; the eleventh is a laſting Plant which grows under Hedges, and in Woods in divers Parts of *England*; but the twelfth Sort is an annual Plant, which is uſually found on dry Hills, in ſome Counties near *London*.

The fourteenth Sort differs from the *common Sea Ragwort* in being much broader-leav'd, and not ſo hoary: This is a laſting Plant, which will endure the Froſt in the open Air very well, and may be treated as is directed for the *common Sea-Ragwort*.

The fifteenth and ſixteenth Sorts are alſo abiding, which may have a Place in large Gardens for the ſake of Variety. Theſe Plants have fine cut Leaves, and the Stems grow erect about two Feet high, on the Tops of which the Flowers grow in an Umbel, which are of a fine yellow Colour.

Theſe may be propagated by Seeds, which ſhould be ſown the Beginning of *March*, on a Bed of light freſh Earth; and when the *Plants* come up, they ſhould be carefully cleared from *Weeds*; and draw out ſome of the Plants where they are very cloſe together, that thoſe remaining may grow ſtronger: When the Plants are ſtrong enough to remove, they ſhould be tranſplanted in a Bed of freſh Earth about ſix Inches apart, where they may remain till *Michaelmas*, being careful to keep them clear from Weeds; then the Plants may be taken up, and tranſplanted into large Borders amongſt other hardy Plants; where they will flower the following Summer, and make an agreeable Variety.

JALAPA: [It is call'd *Marvel of Peru*, becauſe of its Beauty: Hence, by the *French*, it is call'd *Merveille*, and *Belle de Nuit*] Jalap, *or* Marvel of *Peru*.

The *Characters* are;

It hath a long, thick, fleſhy, ſucculent Root: The Leaves, which eſemble thoſe of Nightſhade, *grow by Pairs oppoſite upon the Branches: The Stalks and Branches are very full of Knots: The Flower conſiſts of one Leaf, and is ſhaped like a Funnel: In he Center of the Flower is placed the Ovary, inwrapp'd in one f the Flower-cups, which becomes an oblong, five-corner'd, umilicated Fruit, conſiſting of a mealy Nut.*

The *Species* are;

1. JALAPA *flore flavo. Tourn.* Jalap, *or* Marvel of *Peru*, ith a yellow Flower.
2. JALAPA *flore purpureo. Tourn.* Jalap, *or* Marvel of *eru*, with a purple Flower.
3. JALAPA *flore exalbido. Tourn.* Jalap, *or* Marvel of *eru*, with a whitiſh Flower.
4. JALAPA *flore ex rubro, luteo, & albo mixto. Tourn.* alap, *or* Marvel of *Peru*, with red, yellow, and white Flowrs mix'd upon the ſame Plant.
5. JALAPA *flore ex albo & purpureo elegantiſſime variegato.* alap, *or* Marvel of *Peru*, with white and purple Flowers finely ariegated.
6. JALAPA *parvo flore. Tourn.* Jalap, with a ſmall lower.
7. JALAPA *officinarum, fructu rugoſo. Tourn.* True Jalap f the Shops, with a rough Fruit.

Theſe Plants are all propagated by Seeds, which ſhould be wn upon a moderate Hot-bed in *March*; and when they me up, they ſhould be tranſplanted into another Hot-bed, at x Inches Diſtance from each other; and when they have ken Root, the Glaſſes muſt be rais'd every Day, that the lants may have a great deal of Air, otherwiſe they are very bject to be drawn up tall and weak; nor can they be revered to a ſufficient Strength again in a Month's Time, if ce they are thus drawn. When the Plants are grown to be a Foot high, they ſhould be put into Pots fill'd with rich light Earth, which ſhould be plung'd into a very moderate Hot-bed, to facilitate their taking Root: And in removing them, you muſt be very careful to preſerve as much Earth to their Roots as you can; for their Roots have but few Fibres to retain it in a Ball, as many other Plants will do: And it ſometimes happens, when the Root is left bare, it ſeldom takes freſh Hold of the Ground, at leaſt not in a conſiderable Time; ſo that the Plants will make but a poor Figure that Seaſon. When they are tranſplanted into the Pots, and have taken Root again, they ſhould be harden'd to endure the open Air, for they are not very tender: But, on the contrary, they will not thrive well, if too much drawn or forced in the Hot-bed. In the Middle of *May* the Pots may be removed into the Places where they are deſigned to be continu'd for that Seaſon; obſerving to ſupport the Branches with a ſtrong Stake, and to water them as often as they require it. You may alſo in *May* plant ſome of them into the Middle of the large Borders of the Pleaſure-Garden, doing it carefully, and obſerving to ſhade and water them until they have taken Root; after which, they will require no farther Care but to ſupport them from being broke down by the Winds, which they are very ſubject to be, eſpecially when their Heads are large.

The Plants thus raiſed, will grow to the Height of three or four Feet, and ſpread their Branches very wide, (eſpecially if the Roots have Room in the Pots) and their Flowers will begin to appear in *June*, and they will continue conſtantly flowering until the Froſt prevents them; which, together with the great Diverſity of Colours in the Flowers upon the ſame Plant, renders them valuable to every curious Perſon. The Flowers of theſe Plants never expand in the Day-time while the Sun is hot; but in the Evening, when the Sun declines, they begin to open, and do continue expanded, till the Sun ſhines warm upon them the next Day; ſo that when it happens to be cloudy Weather, as alſo late in the Autumn, when the Weather is cool, the Flowers will remain open moſt Part of the Day.

As the Flowers are produced ſucceſſively almoſt every Day, ſo the Seeds are in a ſhort time after ripe, and do ſoon fall to the Ground; ſo that when your Seeds begin to ripen, you muſt carefully look for them upon the Ground twice a Week; otherwiſe, if they lie too long upon the Ground, and there ſhould fall ſome Rain, they will ſprout, and be good for nothing. In ſowing theſe Seeds, you ſhould be careful to take them from ſuch Plants as produced the greateſt Variety of Flowers; for if you ſave them from ſuch as produce only plain-coloured Flowers, the Seeds will always produce the ſame Sort; and thoſe with yellow and red variegated Flowers will conſtantly produce the ſame; theſe never varying from the Red and Yellow to the Purple and White, tho' they will ſometimes degenerate into plain Yellow or Red Flowers, as will the other into plain Purple or White; but they will conſtantly retain one or both of their original Colours.

Altho' in the above-written Culture of theſe Plants, I have directed their Seeds to be ſown on a Hot-bed, yet they may be propagated by ſowing them in a warm Border of light Earth towards the latter End of *March*; and when the Plants come up, they ſhould be tranſplanted as before directed: In which Method they will ſucceed very well, but will not flower ſo ſoon by a Month or ſix Weeks as thoſe rais'd on the Hot-bed, nor will the Plants grow ſo large.

When the Froſt has pinch'd the Leaves and Stems of theſe Plants, you ſhould take up their Roots, which ſhould be laid to dry, and then may be preſerv'd in dry Sand all the Winter, if ſecured from the Froſt; and in the following Spring theſe Roots ſhould be planted into large Pots, and plung'd into a moderate Hot-bed, to promote their taking Root; and when the Shoots appear above-ground, they ſhould be treated as was directed for the ſeedling Plants, hardening them by degrees to endure the open Air. The Plants ſo raiſed will be much larger than the Seedlings, and will flower earlier in the Year.

Theſe Plants are all affirm'd by *Pere Plumier* to be different Sorts of Jalap; but the ſeventh Sort, he ſays, is the particular Plant, whoſe Root is commonly us'd in Medicine. But I have been ſince inform'd by my worthy Friend Mr. *William Houſtoun*, that the Jalap is the Root of a Convolvulus, and is not akin to either of theſe Plants.

JANUARY:

Work to be done in the Kitchen Garden.

If the Weather be mild, you muſt continue to dig and trench your Ground for Spring Crops, that it may be ready for ſowing or planting the following Months; and on warm Borders and Banks, near Walls, Pales or Hedges, you may now ſow early Radiſhes, Carrots, Spinach, Lettuce, and ſmall Salleting, and put in ſome Peaſe to ſucceed thoſe which were ſown in the Autumn. You may alſo plant the firſt Crop of *Windſor* or *Sandwich* Beans, which will come in as the early *Spaniſh* Beans are going off.

When this Month proves froſty, ſo as that the Ground is frozen ſo hard as not to be dug, (as it often happens) then you may carry Dung upon the Ground, repair Hedges, rub out and clean your Seeds, and prepare all your Tools ready for Uſe againſt the Froſt's going off, that you may not be hindred with theſe Things when every other Part of the Buſineſs is in great Haſte; for if at this Seaſon you omit putting in your Crops, you will find a great Loſs attend it the following Spring.

Make Hot-beds for early Cucumbers and Melons; as alſo for Aſparagus, to ſucceed that which was made the laſt Month, that there may be no Want in the Kitchen, where theſe Things are required.

Sow Creſſes, Muſtard, Rape, Radiſh, Turnep, and other Sorts of ſmall Sallet-Herbs, upon moderate Hot-beds, to bring them forward; for at this Seaſon thoſe Seeds which are ſown in the natural Earth will not come on very faſt, the Ground being cold; and if the Froſt ſhould prove ſevere, thoſe in the open Air would miſcarry.

Look carefully to your Cauliflower-plants, which are under Frames, pulling off all decay'd Leaves from them, which, if permitted to remain upon them, would endanger the Plants, if the Weather ſhould prove ſo bad that the Glaſſes could not be opened for three or four Days to give them Air, which ſometimes happens at this time of the Year; then theſe rotten Leaves cauſe the incloſ'd Air in the Beds to turn rancid and damp, to the great Prejudice of the Plants; therefore you ſhould always pick them off ſo ſoon as they appear, and be ſure to give the Plants as much Air as poſſible in mild Weather; for if they are drawn weak at this Seaſon, they will not be able to reſiſt the Cold of the open Air the next Month, when they ſhould be planted out.

Thoſe who have Cucumber and Melon Plants already up, muſt be very careful of them at this Seaſon, otherwiſe a ſmall Neglect will deſtroy them all: The Beds muſt be conſtantly kept to an equal Temper for Heat, and Air muſt be given to them at every Opportunity, that the Steam of the Bed may paſs off; but this muſt be done with great Care; for if too much cold Air be admitted, it will be equally deſtructive to the Plants; ſo that the great Art in raiſing theſe Plants early, depends upon the juſt obſerving theſe Things.

The Aſparagus-beds, which were made the laſt Month, will now begin to have ſome Buds appear, when you muſt earth them the full Thickneſs over the Crown of the Roots, which ſhould be five or ſix Inches at leaſt; and the Frames ſhould now be put over them; but if you find the Heat of the Bed begin to decline, it will be neceſſary to add ſome hot Dung round the Sides (which, in the Gardener's Phraſe, is called lining the Beds); this will renew the Heat of the Dung, and bring the Aſparagus forward; and you ſhould obſerve alſo to cover the Glaſſes with Mats and Straw every Night and in bad Weather.

Toward the latter End of the Month (if the Seaſon proves mild) you may tranſplant ſome Cabbage-plants of the Sugar-loaf kind, to ſucceed thoſe which were planted out in *November*, and you may ſow the Ground with Spinach before the Plants are planted.

Tranſplant Carrots, Parſnips, Leeks, and Cabbages for Seed, obſerving to hang up the Cabbages by their Stalks in ſome dry Place three or four Days before they are planted, that the Water may drain out from between their Leaves. Theſe ſhould be placed near a Hedge, Pale, or Wall, where they may be ſheltered from ſtrong Winds, which often break down their Branches of Seed in Summer, when they are too much expoſ'd thereto.

You may now deſtroy all Snails and other Vermin, which are at this Seaſon cloſely laid up in the Holes of Walls, and under Reed-hedges, and ſuch other Places of Shelter, where they may be eaſily taken before they get abroad.

Product of the Kitchen Garden.

You have now Cabbages, Savoys, Parſnips, Turneps, Carrots, Potatoes, Leeks, Onions, Garlick, Shalots, Beets, Borecole, *&c.* in Plenty; as alſo Celery, Endive, Lettuce; and upon moderate Hot-beds all Sorts of young Sallet-herbs, as Creſſes, Turnep, Radiſh, Rape, Muſtard, Coriander, and Mint; and Aſparagus on Hot-beds made in *November*: You have alſo Skirrets, Broccoli, Spinach, and Cardoons, with ſome others.

Work to be done in the Fruit Garden.

Cover the Roots of all new-planted Trees with Mulch, to guard them from the Froſt, provided it be not already done, or that it may have waſted; and the Fig-trees, which are againſt Walls, Pales, or Eſpaliers, ſhould be covered either with Mats or Reeds, which will preſerve their tender Shoots from being injured by Froſt, and cauſe the Fruit to come out much earlier in the Spring, and in greater Quantity.

You may now cut out all dead or canker'd Branches from your Standard Fruit-trees; as alſo ſuch as croſs each other, and are ill-plac'd; but be careful in doing this, to make the wounded Part as ſmooth as poſſible, and ſloping, that the Wet may not be detain'd there, and enter to the great Prejudice of the Trees.

If the Seaſon be mild, you may prune Dwarf-trees, and any hardy Sorts of Fruits, as Pears, Apples, and Vines; but Stone-fruit, which was not prun'd in Autumn) ſhould be deferr'd until next Month, becauſe if hard Froſt ſhould ſet in ſoon after they are prun'd, it will penetrate the Wounds of the tender Shoots, and decay them.

Cut Grafts from all the Sorts of early Fruits, laying them in the Earth under a dry Wall or Pale; and if the Weather be ſevere, they ſhould be covered with Litter or Straw, to protect them from Injury. The Reaſon for cutting them ſo early, is to prevent their Buds from ſwelling too much; therefore, as the Winter proves more or leſs ſevere, ſo you muſt be directed to cut the Grafts ſooner or later, according as the Trees are diſpos'd for budding.

In mild Weather you muſt prepare ſuch Borders as are deſign'd for planting with Fruit-trees the ſucceeding Month, laying a good Quantity of freſh Earth therein, making it level, that it may have ſome Time to ſettle before the Trees are planted. You may alſo repair the Borders about old Fruits, which want Amendment, by laying ſome freſh Earth and well-rotted Dung upon them: But if the Trees are old, it will be of little Service to add this near their Stems, for the Roots which ſupply them with Nouriſhment are extended to conſiderable Diſtance; therefore the whole ſhould be amended to the Diſtance of ten or twelve Feet from the Stems, (if poſſible) that the young Roots may receive Nouriſhment therefrom.

Mend and repair all your decay'd Eſpaliers with new Pole where they want them, and faſten ſuch Places where the Pol or Rails are looſe with Wire, which is the ſtrongeſt Faſtnin You muſt alſo plaſh and tye your Fruit-trees thereto wi ſmall Oſier Twigs, but obſerve to train their Branches regularly at proper Diſtances, and not to faſten them too cloſe wi the Twigs, ſo as to pinch the Shoots when they grow the following Summer.

You may yet plant Strawberries and Raſpberries, tho' would have been better if done in Autumn, eſpecially if th Soil be dry. Thoſe who are curious to have early Strawberries, ſhould now plant them in Pots filled with good Eart and place them in a ſheltered Situation till they are roote after which the Pots ſhould be plunged into a moderate Ho bed, which will bring them forward in a ſhort Time. Tho Perſons who are very curious to have early Fruit in forcin Frames, muſt now obſerve to keep up their Heat, whether be Dung or Fire which they uſe; for if, after they have forc the Trees out into Bloſſom, they neglect to keep them nea to the ſame Temperature of Heat, the Bloſſoms will fall and come to nothing. There ſhould alſo be the ſame Care let in freſh Air whenever there are Opportunities; for if th are kept too cloſe, they ſeldom ſucceed well; therefore it not proper to apply the Heat too early to the Trees, becau this Month is often unfavourable to tender Things, and th Air is generally too cold to be admitted to them; ſo that, the Heat be not apply'd before the Beginning of this Month the Bloſſoms will not appear till the Beginning of the ne Month, when the Weather is generally leſs ſevere than in this ſo that there will be leſs Danger of miſcarrying, and the Fru will be ripe almoſt as early as thoſe which were forced all *December*.

Fruits in prime, or yet laſting.

Pears; L'Eſſacherie, Colmar, when well preſerv'd, Virg leuſe, Ambrette, Epine d'Hyver, S. Germain, St. Auguſtin Winter Beurre, Martin Sec, Winter Boncretien, Citro d'Hyver, Rouſelette d'Hyver, Franc Real; and for Bakin the Cadillac, Black Pear of *Worceſter*, Engliſh Warden, a the Pickering.

Apples; Golden Pippen, Nonpareil, French Pippen, Golden Ruſſet, Wheeler's Ruſſet, Pile's Ruſſet, Harvey Apple, Kentiſh Pippen, Holland Pippen, Aromatick Pippen, Winter Pearmain, Monſtrous Rennet, Pear Ruſſet, Aromatick Ruſſet, John Apple, with many others of leſs Note; as alſo Nuts, Almonds, Services, and Medlars.

Work to be done in the Pleaſure Garden *and* Wilderneſs.

In froſty Weather you ſhould cover the Beds of Ranunculus's, Anemonies, Hyacinths, and other choice Flowers: Such of them as are not come up above Ground, may be covered with Peaſe-haulm, or ſome other light Covering, which will admit the Air, but prevent the Froſt from penetrating the Earth: But ſuch of the Flowers as are come up, muſt be arched over with Hoops, and covered with Mats or Cloths; for if they are not protected from the Froſt at this Seaſon, the Roots are many times deſtroy'd; but in mild Weather they ſhould be uncover'd, and expos'd to the Air as much as poſſible; for if they are too cloſely cover'd, they are apt to mould and decay.

Cover all Pots and Tubs of ſeedling Flowers in hard Froſts, and from great Snows, which are very injurious to them, eſpecially to the ſeedling Hyacinths, Perſian Iris's, Spring Cyclamen, and ſome other bulbous-rooted Flowers, which, tho' hardy enough to reſiſt the Cold of our Climate, when their Roots are fully grown, yet, while young, are in Danger of being deſtroy'd by ſevere Froſt.

In mild Weather you may plant ſuch Roots of Ranunculus's, Anemonies, and Tulips, as were kept out of the Ground to retard them, that they might ſucceed thoſe which were planted in Autumn; but this ſhould not be done when the Earth is over-wet, which would endanger the rotting of their Roots.

Turn over your Heaps of Compoſt, that the Froſt may mellow them, and break the Clods; the oftner theſe are turn'd, the ſooner they will be fit for Uſe. You ſhould alſo at this Seaſon make new Parcels for a conſtant Supply; for without this there are but ſmall Hopes of having choice Flowers in any tolerable Degree of Perfection.

Toward the End of this Month, if the Seaſon be mild, you muſt pick off all decay'd Leaves from your Auricula's, and take the Earth out from the Tops of the Pots as low as you can conveniently without diſturbing their Roots, then fill the Pots with freſh rich Earth, which will greatly ſtrengthen their Flowers. You muſt alſo obſerve to place the Pots where they may be ſhelter'd from Froſts, which will blight and deſtroy their Buds, which are forming in the Center of the Plants; but you muſt let them have as much free Air as poſſible in mild Weather, for if they are drawn, it will weaken their Flowers; nor ſhould they be kept too dry, for tho' they require to be guarded from great Rains, yet they ſhould have the Benefit of moderate Showers, which will be of great Service to them.

Your choice Carnations ſhould alſo be guarded from heavy Rains, Snow, and ſevere Froſt, which are often very deſtructive to them; but you muſt give them as much free Air as poſſible in mild Weather, otherwiſe they will draw up weak and come to little. At this Seaſon you muſt be alſo careful to protect them from Vermin, which, for want of other Food, will deſtroy them, particularly Rats and Mice do often make great Havock with them; and where Hares or Rabbets can come to them, they generally make clear Work, ſeldom leaving any in their Reach.

At the latter End of this Month you muſt provide ſome new Dung, which ſhould be thrown on a Heap to warm, to make ſome Hot-beds to ſow the choiceſt Sorts of annual Flowers upon, that they may be brought forward to flower; and this Method will render them ſtronger than if they are ſown later in the Seaſon.

Prune up Wilderneſs Trees, where they grow too much out of Shape, and dig up the Ground in Wilderneſs Quarters, obſerving to clear it from the Roots of all hurtful Weeds. This Digging will be of great Service to the Trees, and add a Neatneſs to the Wilderneſs. But in doing of this you muſt be careful not to diſturb the Roots of thoſe Wood-plants which are intermix'd under the Trees for the ſake of their Flowers.

Plants now in Flower in the open Air.

Winter Aconite, Helleboraſter or Bearsfoot, True Black Hellebore, ſome Single Anemonies, Blue and White Winter Hyacinths, Early Starry Hyacinth, Polyanthus's, Primroſes, Single and Double Snow-drops, Black Hellebore with Green Flowers, Round-leav'd Spring Cyclamen, and, in a warm Situation, the Duke van Tol Tulip.

Hardy Trees and Shrubs now in Flower.

Lauruſtinus, two or three Sorts, Glaſtenbury Thorn, Mezerion, Spurge Laurel, Strawberry Tree, Manna Aſh, Cornelian Cherry, Clematitis Bætica, Alaturnus's, and ſome others.

Work to be done in the Nurſery.

If this Month ſhould prove hard Froſt, you muſt carry on Dung upon the Ground where you intend to tranſplant young Trees or Stocks in the Spring: You may alſo lay ſome Dung between the Rows of young Trees where it is wanted, that it may be ready to be dug in, when the Froſt is gone out of the Ground. You may now trim and plaſh Hedges; but it is better to delay it until the Froſt is over, becauſe where Trees are greatly wounded, the Froſt often penetrates, and greatly injures them.

When the Weather is mild, you ſhould continue trenching the Ground where you intend to plant young Trees in the two following Months; and prepare ſome Beds for ſowing Kernels of Fruit-trees, or Maſt and Berries of Foreſt-trees or flowering Shrubs, which muſt be ſown the latter End of this Month, or the Beginning of the next. You ſhould alſo continue digging the Ground between the Rows of Trees in the Nurſery, being careful not to injure their Roots; but you ſhould ſhorten all ſuch Roots as do extend too far from the Trees, which will cauſe them to put out new Fibres nearer the Stems, and thereby render them much ſafer to tranſplant.

In open Weather you may trim up your hardy Foreſt-trees in the Nurſery; but be careful to leave ſome ſmall Shoots on the Stems of all young Trees, to detain the Sap for the Augmentation of their Stems, otherwiſe they will be too weak to ſupport their Heads, but theſe ſhould not be left in too great Quantity, leſt you prevent the upright Growth of the Trees.

Work to be done in the Green-houſe *and* Stove.

If this Month proves very ſevere (as it often happens) you muſt be careful to keep the Froſt out of your Green-houſe; for if it reaches the Earth of your Orange-trees, it will cauſe all the Fruit to drop off, and many times a great Part of the Leaves alſo; therefore it is very uſeful to have a Flue contriv'd under the Pavement, in the Front of the Green-houſe, which may be uſed in very hard Winters, when it will be very difficult to keep the Froſt out of the Houſe, where it is wanting; but where there is no ſuch Contrivance, you ſhould light three or four large Candles to burn in the Green-houſe every Night: Beſides, in great Thaws, when the Air is fill'd with Moiſture, which occaſions a great Damp in Green-houſes, it will be of great Uſe to make two or three gentle Fires where there are Flues.

You muſt alſo obſerve to pick off all dead Leaves, or ſuch as are mouldy, which, if ſuffered to remain on, would infect thoſe which grow near them, and alſo corrupt the Air of the Houſe, to the Prejudice of your Plants. In mild Weather you muſt let Air into the Houſe, without which the Plants would alter their Colour, and ſometimes caſt their Leaves; but this muſt be done cautiouſly at this Seaſon. You muſt alſo refreſh them with Water, as often as you find it neceſſary, but give it to them ſparingly; for it is better to give it to them often, and in ſmall Quantities, than to over-water them at this Time, becauſe it may prove very hurtful to them, eſpecially if bad Weather ſhould ſet in ſoon after, which will oblige you to keep the Houſe cloſely ſhut up for two or three Days.

The hardy ſucculent Plants muſt have as much Air as poſſible in mild Weather; for if they are too cloſely ſhut up, they often caſt their Leaves, and appear unſightly, eſpecially the Sedums, Cotyledons, Senecio's, and the Ficoides's, which, when drawn too much, will not appear handſome, nor produce near ſo many Flowers, as thoſe which are kept more airy.

Your Anana's, or Pine-Apples, which begin now to ſhew their Heads for Fruit, muſt be carefully look'd after, obſerving to refreſh them frequently with Water, for Want of which they are often ſtarved, and the Fruit is rendred ſmall: But this Water ſhould be placed in the Stove at leaſt twelve Hours before it is uſed, that it may acquire an equal Warmth with the Air of the Houſe, otherwiſe it will be too cold for them. You muſt alſo keep up the Warmth of the Houſe, and not ſuffer the Heat to decline at this Seaſon, leſt you ſtarve the Fruit.

The Coffee-trees, and other woody Plants, which are plac'd in the Bark-bed in the Stove, muſt alſo be often refreſh'd with Water, and their dead or mouldy Leaves conſtantly taken off; and where any of the Leaves have contracted Filth, it ſhould be carefully waſh'd off; as ſhould Inſects, where-ever the Plants are infeſted with them, otherwiſe they will increaſe and ſpread over all the Plants in the Houſe.

If the Bark in the Bed has ſettled unequally (as it often happens) ſo that the Pots do not keep their Poſition, it will be proper to take out the Pots in a fine Day, and ſtir the Bark adding a little new Bark (which has been in ſhelter a Week or ten Days to drain off the Moiſture) and plunge the Pots down again: This will renew the Heat of the Bed, and be very uſeful to the Plants.

The tender Sorts of Aloes, Cereus's, Euphorbiums and Melon Thiſtles, ſhould now have very little Water given to them, for Moiſture at this Seaſon is very injurious to them.

Plants in Flower in the GREEN-HOUSE *and* STOVE.

Double Naſturtium, Alaternoides ericæ folio, Perſian Cyclamens, Senecio Africanus folio retuſo, Geranium with a ſcarlet Flower, Indian yellow Jaſmine, Spaniſh Jaſmine, African Gladiolus, Hæmanthus, Senecio Africanus arboreſcens folio ficoidis, Cryſanthemum populi folio, Jaſminum Ilicis folio, Aloe Succotrina, Aloe Margaritifera major & minor, Cuſhion Aloe, Hedgehog Aloe, Partridge-Aloe, Doria Africana atriplicis folio, Anemonoſphermos's of ſeveral Sorts, Aſcyron Balearicum, Canary Campanula, Ficoides's of ſeveral Sorts, Amomum Plinii in Fruit, with Oranges and Lemons.

JASMINOIDES, Baſtard Jaſmine.

The *Characters* are;

It hath a tubulous bell-ſhap'd Flower conſiſting of one Leaf, which is cut into five ſhort Segments; from the Flower-cup (which is alſo divided into five Parts) ariſes the Pointal, fixed like a Nail in the inner-part of the Flower, which afterwards becomes a round ſoft Fruit or Berry, in which are twelve or fourteen Seeds.

The *Species* are;

1. JASMINOIDES *Africanum, jaſmini aculeati foliis & faciæ. Ac. Reg. Scien.* Baſtard Jaſmine with Leaves and the Face of prickly Jaſmine.
2. JASMINOIDES *laureolæ folio, flore candido, interdiu odorato. Hort. Elth.* Baſtard Jaſmine with a large laurel Leaf, and a white Flower, which ſmells ſweet in the Day.
3. JASMINOIDES *folio piſhaminis, flore vireſcente, noctu odoratiſſimo. Hort. Elth.* Baſtard Jaſmine with a piſhamin Leaf, and a greeniſh Flower, which is very ſweet in the Night.
4. JASMINOIDES *arboreſcens, nicotianæ folio, flore albo. Houſt.* Tree-like Baſtard Jaſmine, with a Tobacco Leaf, and a white Flower.
5. JASMINOIDES *aculeatum, ſalicis folio, flore parvo ex albo purpuraſcente. Michel. Nov. Gen.* Prickly Baſtard Jaſmine, with a willow Leaf, and a ſmall Flower of a purpliſh white Colour.
6. JASMINOIDES *aculeatum humile, halimi minoris folio, flore majori violaceo, fructu craſſiore, per maturitatem flaveſcente. Michel. Nov. Gen.* Dwarf prickly Baſtard Jaſmine, with a leſſer halimus Leaf, a larger violet-coloured Flower, and a thicker Fruit, which turns yellowiſh when ripe.

The firſt and fifth Sorts have been old Inhabitants in the *Engliſh* Gardens, and have been generally known by the Name of *Rhamnus* or *Buckthorn*. They are pretty hardy Shrubs, which in very mild Winters will live Abroad in the open Air; but in hard Froſt they are deſtroyed where they are not protected: ſo that they are generally kept in Pots or Tubs, and removed into the Green-houſe in Winter.

The ſixth Sort is more rare in *England* than either of the former, but is very common in *Italy*. This is as hardy as the two former, and may be treated in the ſame manner.

Theſe Plants may be propagated by Cuttings, which ſhould be planted the Beginning of *May* on a Border of light freſh Earth, obſerving to water and ſhade them until they have taken Root, and conſtantly keep 'em clear from Weeds. When theſe Cuttings are ſtrongly rooted, (which may be known by their ſending forth ſtrong Shoots) they ſhould be carefully taken up with Balls of Earth to their Roots, and planted each into a ſeparate Pot filled with freſh light Earth; and then placed in a ſhady Situation; until they have taken new Root; after which Time they ſhould be removed into a ſheltered Situation, where they may remain with other pretty hardy exotic Plants, until the Beginning of *November*; when they ſhould be removed into Shelter, with *Bays*, *Oleanders*, and other ſuch hardy Plants, as only require to be ſheltered from extreme Froſt; but ſhould have as much free Air as poſſible in mild Weather.

In Summer theſe Plants muſt be plentifully watered in dry Weather, for they are very thirſty; there ſhould alſo be Care taken that they do not root thro' the Pots into the Ground, which they are very apt to do, if they are permitted to ſtand long in a Place unremoved; ſo that, when their Roots are torn off by taking of them up, the Leaves are apt to fall, and their young Shoots will wither. In Winter theſe Plants muſt be frequently watered while they are in the Green-houſe; but the Water muſt not be given to them in ſo large Quantities at that Seaſon as in Summer.

Theſe Plants may alſo be propagated by laying down their tender Branches in the Spring of the Year, which, if duly watered, will take Root by Autumn, when they ſhould be taken off from the old Plants, and planted in Pots, as was directed for the Cuttings. As theſe Plants ſhoot very freely, ſo they ſhould be pruned, to reduce them and keep them in Compaſs; otherwiſe they will grow very rude and unſightly, and their Heads will ſoon grow too large for their Stems; they ſhould alſo be ſhifted out of the Pots at leaſt once a Year, when their Roots ſhould be well trimmed; and as their Roots increaſe in Bulk, ſo they muſt be put into larger Pots.

The firſt Sort will flower very freely moſt part of Summer, and where the Plants are duly water'd, they will often produce ripe Fruit, and flower again in Winter.

But the fifth and ſixth Sorts do not flower ſo kindly in *England*, tho' they ſhoot moſt luxuriantly, when their Roots are not too much confined.

The ſecond, third and fourth Sorts are much tenderer Plants than the former, theſe being Natives of the warmeſt Parts of *America*: the Seeds of the ſecond Sort I received from the *Spaniſh Weſt-Indies*, by the Name of *Dama de Dia*; and the third, by the Name of *Dama de Noche*; the Flowers of one Sort being very ſweet in the Day, and thoſe of the other being ſweet in the Night.

The fourth Sort was diſcovered by Father *Plumier* in the *French* Settlements in *America*, who calls it in his Catalogue, *Jaſminum arboreſcens, nicotianæ folio, flore albo.* But I received the Seeds of this Sort from *la Vera Cruz*, which were ſent me by the late Dr. *William Houſtoun*, who had carefully examined the Flowers and Fruit of this Plant, and accordingly ranked it amongſt the *Baſtard Jaſmines*.

Theſe three Sorts may be propagated either by Seeds or Layers; but as they do not produce Seeds in this Country, ſo their Seeds muſt be procured from the Places of their natural Growth. If they are propagated by Seeds, they ſhould be ſown in the Spring in Pots filled with light freſh Earth, covering them about a quarter of an Inch with Mould; then plunge the Pots into a Hot-bed of Tanners-bark, obſerving to water the Earth as often as it appears dry; for if the Earth is not kept moiſt and warm, the Seeds will not vegetate; therefore, if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats, to preſerve a moderate Heat in the Bed; but in the Day-time, when the Sun ſhines warm, the Glaſſes ſhould be raiſed to let the Steam of the Bed paſs off, as alſo to admit freſh Air. When the Plants begin to appear, they muſt be duly watered, and carefully cleared from Weeds, obſerving to admit freſh Air to them in hot Weather, as alſo to cover the Glaſſes every Night, when it is cold, to keep them warm. When the Plants are about three Inches high, they ſhould be ſhaken out of the Pots carefully, and each tranſplanted into a ſeparate ſmall Pot filled with light freſh Earth, and then plunged into the Hot-bed again, obſerving to ſhade the Plants from the Heat of the Sun until they have taken new Root; after which Time the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants in proportion to the Warmth of the Seaſon; and they muſt be conſtantly watered in hot Weather, for they are thirſty Plants. When the Plants are grown ſo tall as to reach near the Glaſſes, they ſhould be removed out of the Hot-bed, and plunged into the Bark-bed in the Stove, where they muſt remain all the Winter; during which Seaſon they muſt be kept very warm, and muſt be frequently refreſhed with Water. With this Management they will thrive very faſt, and the following Summer will produce their Flowers; but they ſhould be conſtantly kept in the Stove, giving them a larger Share of freſh Air in Summer as alſo Plenty of Water; for if they are placed Abroad in Summer, they will not produce their Flowers, nor will their Leaves continue in Beauty; for as the Weather often alters in this Climate, ſo, whenever it is cold or ſtormy Weather, theſe Plants, when expoſed thereto, are ſo much pinched as not to recover their Verdure till after they have been removed into the Stove for ſome Time; and often, when they are much pinched by cold Nights or Winds in Summer, they do not recover till the following Spring.

If you propagate theſe Plants by Layers, ſome of their tender Branches ſhould be laid down in *April*; and if the Pots are at that time placed in a warm Bed of Tanners-bark, it will greatly promote their Rooting, eſpecially if they are duly watered. Theſe Layers will be ſufficiently rooted for Tranſplantation in about three Months after Laying; when they ſhould be raiſed up, and cut off from the old Plants, and each planted into a Pot filled with light rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken new Root; after which Time they may be treated as has been directed for the ſeedling Plants.

The ſecond Sort may alſo be propagated by Cuttings, which ſhould be planted in *May*, in Pots filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Heat of the Sun until they have taken Root, as alſo to give them Plenty of Water. When the Cuttings are well rooted, they ſhould be each planted into a ſeparate Pot, and managed as the Layers.

JASMINUM, [This Name is *Arabick*] The Jaſmine, *or* Jeſſamine-Treee.

The *Characters* are;

The Leaves are in many Species pinnated; the Cup of the Flower conſiſts of one Leaf, but is divided at the Top into five Segments; the Flower conſiſts of one Leaf, is Funnel-ſhap'd, and divided into five Segments: The Flowers are ſucceeded by Berries, which ſplit in the Middle, each Side for the moſt part containing a ſeparate Seed.

The *Species* are;

1. JASMINUM *vulgatius, flore albo.* C. B. P. The common white Jaſmine.
2. JASMINUM *vulgatius, flore albo, foliis ex luteo elegantiſſime variegatis.* The common white Jaſmine, with yellow ſtrip'd Leaves.
3. JASMINUM *vulgatius, flore albo, foliis ex albo elegantiſſime variegatis.* The common white Jaſmine, with white ſtrip'd Leaves.
4. JASMINUM *humile luteum.* C. B. P. Dwarf yellow Jaſmine, *commonly called*, The Italian yellow Jaſmine.
5. JASMINUM *luteum, vulgo dictum bacciferum.* C. B. P. The common yellow Jaſmine.
6. JASMINUM *humilius magno flore.* C. B. P. The Spaniſh white, *or* Catalonian Jaſmine.
7. JASMINUM *humilius, magno flore pleno.* The double Spaniſh Jaſmine.
8. JASMINUM *Indicum flavum odoratiſſimum.* *Fer. Flor.* The yellow Indian Jaſmine.
9. JASMINUM *Azoricum trifoliatum, flore albo, odoratiſſimum.* H. A. The Three-leav'd Azorian Jaſmine, with very ſweet white Flowers, *commonly called*, The Ivy-leav'd Jaſmine.
10. JASMINUM *Africanum, folio ilicis, flore ſolitario, ex alis foliorum proveniente, albo.* *Com. Rar.* African Ilex-leav'd Jaſmine, with a ſingle white Flower produced from the Wings of the Leaves.
11. JASMINUM *ſive Sambach Arabum, Alpini.* J. B. The ſingle Arabian Jaſmine.
12. JASMINUM *Arabicum, foliis limonii conjugatis, flore albo pleno odoratiſſimo.* *Boerh. Ind.* The double Arabian Jaſmine.
13. JASMINUM *Arabicum, caſtaneæ folio, flore albo odoratiſſimo, cujus fructus Coffee in officinis dicuntur nobis.* *Com. Pl. Uſ.* The Coffee-Tree.
14. JASMINUM *Malabaricum, foliis mali aurantii, flore niveo odoratiſſimo.* *Com.* Jaſmine of Malabar, with Orange Leaves, and a ſnow-white very ſweet ſcented Flower.
15. JASMINUM *Americanum, foliis conjugatis, floribus ſpicatis albis.* *Houſt.* American Jaſmine, with Leaves growing oppoſite, and white Flowers growing in Spikes.
16. JASMINUM *arboreſcens, foliis laurinis, flore umbellato.* *Houſt.* Tree-like Jaſmine, with Bay Leaves, and Flowers growing in an Umbel.

The firſt Sort is very common in moſt *Engliſh* Gardens, being much cultivated for the Sweetneſs of its Flowers. The ſecond and third Sorts are accidental Varieties from the firſt, and may be obtain'd by inoculating the Buds of theſe into the common *Jaſmine*; which, altho' the Buds ſhould periſh, (as it often happens) yet it ſeldom fails to ſtain both the Leaves and Branches of the old Plant into which the Buds were put: So that by inoculating ſome of theſe Buds into ſome young Branches in divers Parts of an old Tree, they will not fail to tinge the whole Tree in a ſhort Time.

The common white *Jaſmine* is eaſily propagated by laying down the tender Branches in the Spring, which, by the ſucceeding Spring, will be rooted ſtrong enough to be tranſplanted. They may alſo be propagated by Cuttings, which ſhould be planted in *March* in a moiſt Border, where they may have the Morning Sun: But they muſt be ſkreen'd from the Violence of the Sun in the Heat of the Day, and frequently water'd in dry Weather. The Cuttings thus manag'd, will many of them live, and have Roots fit to be removed in the following Spring: But this Method is ſeldom practiſed, the Layers always making the beſt Plants.

When theſe Plants are remov'd, they ſhould be planted where they are deſign'd to be continued, which ſhould be either againſt ſome Wall, Pale, or other Fence, where the flexible Branches may be ſupported: For altho' it is ſometimes planted as a Standard, and form'd into a Head, yet it will be very difficult to keep it in any handſome Order; or if you do, you muſt cut off all the flowering Branches: For the Flowers are always produc'd at the Extremity of the ſame Year's Shoots, which, if ſhortned before the Flowers are blown, will intirely deprive the Trees of Flowers. Theſe Plants ſhould be permitted to grow rude in the Summer, for the Reaſon before given: Nor ſhould you prune and nail them until the Middle or latter End of *March*, when the froſty Weather is paſt; for if it ſhould prove ſharp froſty Weather after their rude Branches are prun'd off, and the ſtrong ones are expos'd thereto, they are very often deſtroyed; and this Plant being very backward in Shooting, there will be no Danger of hurting them by late pruning.

The two ſtrip'd Sorts ſhould be planted in a warm Situation, eſpecially the white ſtrip'd, for they are much more tender than the plain, and are very ſubject to be deſtroy'd by great Froſts, if they are expos'd thereto; therefore it will be proper to preſerve a Plant of each Kind in Pots, which may be removed into the Green-houſe in Winter, leſt, by expoſing them to the Cold, they ſhould all be deſtroyed, and ſo you loſe the Sorts.

The common yellow *Jaſmine* was formerly in greater Plenty in *England* than at preſent, and was planted againſt Arbours, *&c.* to cover them, tho' it is not near ſo proper for that Purpoſe as the white Sort, it being of much ſlower Growth, nor will it ever extend its Branches ſo far as that; but however, it may have a Place among the flowering Shrubs of low Growth, where it may be with more Eaſe reduced to a Standard than the other. This Plant flowers in *May* and *June*; but they have very little Scent, which has occaſioned its being leſs regarded. It may be propagated by Suckers, which it generally produces in great Numbers; or by Layers, as was directed for the common Sort, and be full as hardy.

The Dwarf yellow *Jaſmine* is ſomewhat tenderer than the former; yet will it endure the Cold of our ordinary Winters, if it be planted in a warm Situation. The Flowers of this Kind are generally larger than thoſe of the common Sort, and better ſcented, but are ſeldom produced ſo early in the Seaſon. It may be propagated by laying down the tender Branches, as was directed for the common white Sort; or by budding or inarching it upon the common yellow *Jaſmine*; the latter of which is preferable, as making the Plants hardier than thoſe which are obtain'd from Layers: They ſhould be planted againſt a warm Wall; and in very ſevere Winters will require to be ſheltered with Mats, or ſome other Covering, otherwiſe they are ſubject to be deſtroyed. The Manner of Dreſſing and Pruning being the ſame as was directed for the white *Jaſmine*, I ſhall not repeat it.

The *Spaniſh* white, or *Catalonian Jaſmine*, is one of the moſt beautiful of all the Sorts, as alſo extremely ſweet-ſcented: The Flowers of this Kind are much larger than any of the others, and are commonly of a red Colour on the Outſide. This Plant is propagated by Budding or Inarching it upon the common white *Jaſmine*, on which it takes very well, and is rendered hardier than thoſe which are upon their own Stocks But thoſe of this Kind being brought over from *Italy* every Spring in ſo great Plenty, they are ſeldom raiſed here: I ſhall therefore proceed to the Management of ſuch Plants as are uſually brought into *England* from the Place above-mentioned, which generally are ty'd up in ſmall Bunches, containing three or four Plants, and wrapped about their Roots with Moſs, to preſerve them from drying: Which, if it happen that the Ship has a long Paſſage, will often occaſion them to puſh out ſtrong

Shoots from their Roots, which muſt always be taken off before planted, otherwiſe they will exhauſt the whole Nouriſhment of the Plant, and deſtroy the Graft.

When you receive theſe Plants, you muſt clear the Roots of the Moſs, and all decay'd Branches ſhould be taken off; then place their Roots into a Pot or Tub of Water, which ſhould be ſet in the Green-houſe, or ſome other Room, where it may be ſkreen'd from the Cold: In this Situation they may continue two Days; after which you muſt prune off all the dry Roots, and plant them into Pots fill'd with freſh light Earth; then plunge the Pots into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them, as the Heat of the Seaſon may require. In about three Weeks or a Month's Time they will begin to ſhoot, when you muſt carefully rub off all ſuch as are produc'd from the Stock below the Graft; and you muſt now let them have a great Share of Air, by raiſing the Glaſſes in the Heat of the Day: And as the Shoots extend, they ſhould be topp'd, to ſtrengthen them, and, by Degrees, ſhould be hardened to endure the open Air, into which they ſhould be removed in *June*: But muſt have a warm Situation the firſt Summer; for if they are too much expos'd to the Winds, they will make but indifferent Progreſs, being rendered ſomewhat tender by the Hot-bed. If the Summer be warm, and the Trees have ſucceeded well, they will produce ſome Flowers in the Autumn following, tho' they will be few in Number, and not near ſo ſtrong as they will be the ſucceeding Years, when the Trees are ſtronger, and have better Roots.

Theſe Plants are commonly preſerv'd in Green-houſes, with Oranges, Myrtles, *&c.* and, during the Winter-ſeaſon, will require to be frequently water'd, which ſhould be given them ſparingly each Time, eſpecially in cold Weather; for too much Wet at that Seaſon will be apt to rot the Fibres of their Roots: They ſhould alſo have a great Share of free Air, when the Weather will permit; for which Purpoſe they ſhould be placed in the cooleſt Part of the Green-houſe, among Plants that are hardy, where the Windows may be opened every Day, except in froſty Weather: nor ſhould they be crouded too cloſe among other Plants, which often occaſions their growing mouldy, and decays the younger Branches. In *April* the Shoots of theſe Plants ſhould be ſhorten'd down to four Eyes, and all the weak Branches ſhould be cut off; and if you have the Conveniency of a Glaſs Stove, or a deep Frame, to place the Pots into at that Seaſon, to draw them out again, it will be of great Service in forwarding their flowering: Yet ſtill you ſhould be careful not to force them too much; and as ſoon as they have made Shoots three or four Inches long, the Glaſſes ſhould be opened in the Day-time, that the Plants may by degrees be inur'd to the open Air, into which they ſhould be removed by the latter End of *May*, or the Beginning of *June*, otherwiſe their Flowers will not be ſo fair, nor continue ſo long. If the Autumn proves favourable, theſe Plants will continue to produce freſh Flowers until *Michaelmas*; and ſometimes, when they are ſtrong, they will continue flowering till *Chriſtmas*, or after: But then they muſt have a great Share of Air when the Weather is mild and will admit of it, otherwiſe the Flower-buds will grow mouldy, and decay.

But notwithſtanding moſt People preſerve theſe Plants in Green-houſes, yet they will endure the Cold of our ordinary Winters in the open Air, if planted againſt a warm Wall, and covered with Mats in froſty Weather; they'll alſo produce ten Times as many Flowers in one Seaſon as thoſe kept in Pots, and the Flowers will likewiſe be much larger: But they ſhould not be planted abroad till they have ſome Strength; ſo that it will be neceſſary to keep them in Pots two or three Years, whereby they may be ſhelter'd from the Froſt in Winter: And when they are planted againſt the Wall, which ſhould be in *May*, that they may take good Root in the Ground before the ſucceeding Winter, you muſt turn them out of the Pots, preſerving the Earth to their Roots; and having made Holes in the Border where they are to be planted, you ſhould place them therein, with their Stems cloſe to the Wall; then fill up the Holes round their Roots with good freſh rich Earth, and give them ſome Water, to ſettle the Ground about them, and nail up their Shoots to the Wall, ſhortening ſuch of them as are very long, that they may puſh out new Shoots below, to furniſh the Wall, continuing to nail up all the Shoots as they are produced. In the middle, or toward the latter End of *July*, they will begin to flower, and continue to produce new Flowers until the Froſt prevents them; which, when you obſerve, you ſhould carefully cut off all the Tops of ſuch Shoots as have Buds form'd upon them, as alſo thoſe which have the Remains of faded Flowers left; for if theſe are ſuffered to remain on, they will ſoon grow mouldy, eſpecially when the Trees are cover'd, and thereby infect many of the tender Branches, which will greatly injure the Trees.

Toward the middle of *November* (if the Weather be cold, and the Nights froſty) you muſt begin to cover your Trees with Mats, which ſhould be nail'd over them pretty cloſe; but this ſhould be done when the Trees are perfectly dry, otherwiſe the Wet being lodged upon the Branches, will ſoon cauſe a Mouldineſs upon them, and the Air being excluded therefrom, will rot them in a ſhort Time; it will alſo be very neceſſary to take off theſe Mats as often as the Weather will permit, to prevent this Mouldineſs, and only keep them cloſe covered in froſty Weather, at which Time you ſhould alſo lay ſome Mulch upon the Surface of the Ground about their Roots, and faſten ſome Bands of Hay about their Stems, to guard them from the Froſt; and in very ſevere Weather, you ſhould add a double or treble Covering of Mats over the Trees, by which Method, if duly executed, you may preſerve them thro' the hardeſt Winters. In the Spring, as the Weather is warmer, ſo you ſhould by degrees take off the Covering; but you ſhould be careful not to expoſe them too ſoon to the open Air, as alſo to guard them againſt the Morning Froſts, and dry Eaſterly Winds, which often reign in *March*, to the no ſmall Deſtruction of tender Plants, if they are expoſed thereto; nor ſhould you quite remove your Covering until the middle of *April*, when the Seaſon is ſettled, at which time you ſhould prune the Trees, cutting out all decayed and weak Branches, ſhortening the ſtrong ones to about two Feet long, which will cauſe them to ſhoot ſtrong, and produce many Flowers.

The Double of this Kind is at preſent very rare in *England*, and only to be found in ſome very curious Gardens; tho' in *Italy* it is pretty common, from whence it is ſometimes brought over amongſt the Single: The Flowers of this Kind have only two Rows of Leaves, ſo that it is regarded rather for its Curioſity, than for any extraordinary Beauty in the Flowers: This may be propagated by budding it upon the common White *Jaſmine*, as has been directed for the Single, and muſt be treated in the ſame Manner.

The Yellow *Indian Jaſmine* is propagated either by Seeds, or laying down the tender Branches: If you would propagate them by Seeds, (which they often produce in *England* in great Plenty) you ſhould make a moderate Hot-bed in the Spring, into which you ſhould plunge ſome ſmall Pots, filled with freſh light Earth, and in a Day or two after, when you find the Earth in the Pots warm, you muſt put your Seeds therein, about four in each Pot will be ſufficient, covering them about half an Inch thick with the ſame light Earth, and obſerve to refreſh the Pots with Water as often as you ſhall perceive the Earth dry; but do not give them too much at each Time, which would be apt to rot the Seeds.

In cold Weather, and in the Night, theſe Beds muſt be covered with Mats over the Glaſſes; but in warm Weather, the Glaſſes ſhould be raiſed with Stones, to admit freſh Air, as alſo to let out the Steam of the Bed. In about five or ſix Weeks after ſowing, the Plants will appear above Ground, at which Time it will be neceſſary to remove the Pots into another freſh Hot-bed, of a moderate Temperature, in order to bring the Plants forward; you muſt alſo be careful to water them as often as is neceſſary, and in the great Heat of the Day the Glaſſes ſhould be tilted pretty high, and ſhaded with Mats, to prevent the Plants from being ſcorched with Heat; about the Middle of *May* you ſhould begin to harden them to the open Air, by taking off the Glaſſes when the Weather is warm; but this muſt be done cautiouſly, for you ſhould not expoſe them to the open Sun in a very hot Day at firſt, which would greatly injure them; but rather take off the Glaſſes in warm, cloudy Weather at firſt, or in gentle Showers of Rain, and ſo by degrees inure them to bear the Sun, and in *June* you ſhould take the Pots out of the Hot-bed, and carry them to ſome well-ſheltered Situation, where they may remain until the Beginning of *October*; at which Time they muſt be carried into the Green-houſe, obſerving to place them where they may enjoy as much free Air as poſſible when the Windows are opened, as alſo to be clear from the Branches of other Plants.

During the Winter-Seaſon they will require to be often watered, but you muſt be careful not to give them too much at each Time; and in *March* you muſt remove theſe Plants each into a ſeparate Pot, being careful not to take the Earth from their Roots; and if at this Time you plunge them into a freſh moderate Hot-bed, it will greatly facilitate their Rooting again, and be of great Service to the Plants; but when you perceive they are rooted, you muſt give them a great deal of Air; for if you draw them too much, they will become weak in their Stems, and incapable to ſupport their Heads, which is a great Defect in theſe Trees.

You muſt alſo harden them to the open Air, into which they ſhould be removed about the Middle of *May*, obſerving, as was before directed, to place them in a Situation that is defended from ſtrong Winds, which are injurious to theſe Plants, eſpecially while they are young. In Winter houſe them, as before, and continue the ſame Care, with which they will thrive very faſt, and produce annually great Quantities of Flowers.

Theſe Plants are pretty hardy, and will require no other Care in Winter, than only to defend them from hard Froſts; nor do I know whether they would not live in the open Air, if planted againſt a warm Wall, which is what I am this Year [1730] trying, for I have planted ſome againſt a Wall for that Purpoſe, and I think we have little Reaſon to doubt of the Succeſs, ſince they are much hardier than the *Spaniſh*; but there is this Difference between them, *viz.* theſe Plants have large, thick, ever-green Leaves, ſo that if they were covered with Mats, as was directed for the *Spaniſh Jaſmine*, the Leaves would rot and decay the Shoots; but as theſe will only require to be covered in extreme Froſt, ſo, if their Roots are well mulch'd, and a Mat or two looſely hung over them in ordinary Froſts, it will be ſufficient, and theſe Mats being either rolled up, or taken quite off in the Day, there will be no great Danger of their being hurt, which only can proceed from being too long cloſe covered.

In the Spring theſe ſhould be pruned, when you ſhould cut off all decay'd Branches; but you muſt not ſhorten any of the other Branches, as was directed for the *Spaniſh* Sort; for the Flowers of this Kind are produced only at the Extremity of the Branches, which, if ſhorten'd, they would be cut off, and this growing of a more ligneous Subſtance in the Branches than the other, will not produce Shoots ſtrong enough to flower the ſame Year.

If you would propagate this Plant from Layers, the Shoots ſhould be laid down in *March*; and if you give them a little Cut at the Joint, (as is practiſed in laying of Carnations) it will promote their Rooting: You ſhould alſo obſerve to refreſh them often with Water, when the Weather is dry; which, if carefully attended to, the Plants will be rooted by the ſucceeding Spring fit to be tranſplanted, when they muſt be planted in Pots filled with light Earth, and managed, as was before directed for the ſeedling Plants.

The *Azorian Jaſmine* is alſo pretty hardy, and requires no more Shelter than only from hard Froſts; and I am apt to think, if this Sort was planted againſt a warm Wall, and managed, as hath been directed, for the Yellow *Indian Jaſmine*, it would ſucceed very well; for I remember to have ſeen ſome Plants of this Kind growing againſt a Wall in the Gardens at *Hampton-Court*, where they had endured the Winter, nd were in a more flouriſhing State than ever I ſaw any of the Kind in Pots, and produced a greater Quantity of Flowers. Theſe Plants are propagated in the ſame Manner as the yellow *Indian*, and require the ſame Management. The Flowers of his Kind are ſmall, but being produced in large Bunches, do make a handſome Figure, and are of a very agreeable Scent, nd the Leaves being large and of a ſhining green Colour, add o the Beauty of the Plant very much.

The *Ilex-leav'd Jaſmine* affords the leaſt Pleaſure of any of he Kinds of *Jaſmines*, the Flowers being only produced ſingly rom the Wings of the Leaves, and are very ſmall; the Leaves lſo are of a pale Green, and the Plant naturally growing very agged, has occaſion'd its being but little valued; however, it hould not be wanting in good Collections of Plants, for tho' he Flowers are ſmall and produc'd ſingly, yet it continues owering moſt part of the Year. This Plant is propagated by lanting Cuttings in any of the Summer-months, which ſhould e put into Pots fill'd with light ſandy Earth, and plunged into Hot-bed, obſerving to water and ſhade them as the Seaſon ay require. When theſe are rooted, (which will be in about ve or ſix Weeks Time) they may be remov'd into ſeparate ots; and when they have taken freſh Root, they may be reoved into a Situation where they may be defended from rong Winds, in which Place they may remain until the midle of *October*; at which Time they muſt be hous'd with *Geraniums*, &c. obſerving to water them frequently, and give em as much free Air as poſſible, when the Weather is mild nd will permit; for if they are too much drawn in Winter, eir tender Shoots will be ſubject to grow mouldy and rot. heſe Plants ſhould be often renew'd by planting Cuttings, for e old ones are very ſubject to decay.

The *Arabian Jaſmines* of both Sorts are commonly brought to *England* from *Genoa* every Spring amongſt the *Spaniſh aſmines*. Theſe are all grafted upon the common *Jaſmine* ock, as are the *Spaniſh*; but being much tenderer than thoſe, e very often greatly injured in their Paſſage, (which is always the Winter-ſeaſon) ſo that you ſhould carefully examine em (when you purchaſe them of the *Italians*, who bring them over) to ſee if their Grafts are freſh and ſound; if ſo, there is little Danger of ſucceeding. Theſe muſt be put into Water and waſhed, pruning their Roots and Branches, and planting them as was directed for the *Spaniſh Jaſmines*, to which I ſhall refer the Reader, to avoid Repetition.

Theſe Plants are more tender than any of the Sorts beforementioned, and muſt be preſerved in a warm Stove in Winter, nor ſhould they be expoſed to the open Air in Summer, if you would have them flower well, (tho' indeed the Plants will live and thrive in the open Air in *June*, *July*, and *Auguſt*) but then they will rarely produce any Flowers; and thoſe which may appear, are ſoon deſtroy'd by either Winds or Rain, both which will ſoon ſcatter them, being but ſlenderly faſtened upon the Plants. The only Method in which I have found theſe Plants to thrive and flower well is this, *viz.* After having preſerved the Plants in a moderate Stove all the Winter, I clean'd their Leaves and Stems from Duſt; then I took out the Earth from the upper Part of the Pots, and refill'd them with freſh Earth; then I plunged the Pots into a moderate Bed of Tanners-bark, which had loſt moſt of its Heat: This occaſioned the Plants to ſhoot very ſtrong, and in *June* and *July* I had great Quantities of Flowers, which were exceeding ſweet, but of a ſhort duration, ſeldom continuing longer than two Days: However theſe were ſucceeded by freſh Flowers thro' the greateſt Part of *June* and *July*, during which Time my Plants were never entirely deſtitute of Flowers.

Theſe *Jaſmines* may alſo be propagated by laying down their tender Branches in the Spring, in the ſame Manner as was directed for the yellow *Indian Jaſmine*, which will take Root in leſs than three Months, provided the Pots are plunged into a Hot-bed, otherwiſe they will not be rooted until the ſucceeding Spring. Theſe muſt be planted into a light ſandy Earth, and frequently watered in hot Weather; but during the Winter-ſeaſon, it muſt be given them but ſparingly, for too much Moiſture at that Time will deſtroy them.

The Sort with double Flowers, which we have now in *England*, has rarely more than two Rows of Leaves, (as I obſerved in the *Spaniſh*) ſo that it is but little better than the ſingle: But there is another Sort of this *Jaſmine*, which was formerly in *England*, and is now in the Duke of *Tuſcany*'s Gardens at *Piſa*, which produces Flowers almoſt as large as a Cinnamon Roſe, and as double, as alſo of a moſt inoffenſive ſweet Scent; but this is not in *England* at preſent, nor is it likely to be obtained here, ſince it is not known to be growing in any other Part of *Europe* but the Garden at *Piſa*, where it is kept under a Guard to prevent its being ſtolen away: Such is the narrow Temper of the preſent Poſſeſſor, that he will not ſuffer it to be diſtributed into any other Gardens; tho' the Profeſſor of Botany to that Garden ſays, it increaſes greatly by Layers, by which Means all *Europe* might be ſoon ſupply'd with this valuable Plant, were it but once in the Poſſeſſion of any communicative Perſon.

The *Coffee-tree* is propagated by Seeds, which ſhould be ſown ſoon after they are gathered from the Tree: for if they are kept but a ſhort Time out of the Ground, they will not grow, which is the chief Reaſon that this Tree has not been ſpread into more different Countries; for the Seeds will not keep good long enough to be ſent to any diſtant Place: ſo that, in order to cultivate this Plant in any Part of the World, it is abſolutely neceſſary to have it carry'd thither growing. But as this Difficulty is now overcome, by the Quantity of theſe Trees there are now growing both in *Europe* and *America*, ſo we may expect to be furniſhed with them from many different Parts, but eſpecially from the *Caribbee Iſlands*, where the Trees are found to ſucceed as well as in their native Place of Growth: But whether the *Coffee* produced in the *Weſt-Indies* will prove as good as that brought from *Mocha*, Time will diſcover; but if it ſhould, it may be of great Advantage not only to the Inhabitants there, but alſo may turn to great Account to the *Weſt-Indies* Trade. The Manner how this Tree was firſt brought into *Europe*, and the ſeveral Parts of the World to which it is now ſpread, may be fully ſeen in Doctor *Douglaſs*'s curious Account of the *Coffee*, publiſhed at *London*, *Anno* 1727.

The Berries of this Plant are commonly ripe with us in *April*, at which time they ſhould be ſown in Pots of freſh light Earth, covering them about half an Inch thick with the ſame light Earth; then plunge the Pots into a moderate Hotbed of Tanner's Bark, obſerving to refreſh them often with Water, as alſo to raiſe the Glaſſes in the Heat of the Day, to admit freſh Air; and in very hot Weather it will be proper to ſhade the Glaſſes with Mats, for otherwiſe the Earth in the Pots will dry too faſt, and prevent the Vegetation of the Seeds. I muſt here obſerve, that the taking off the Pulp of the Berries, which has been by ſome People directed as abſolutely neceſſary before they are planted, is a great Miſtake; for I have experienced, that thoſe Berries which were planted whole as they came from the Tree, produced ſtronger Plants, and came up ſooner, than thoſe which were cleared from the Pulp; and altho' they are commonly two Seeds in each Berry, (both which ſeldom fail to grow) yet when the Plants are young, they are eaſily parted and planted into ſeparate Pots; which is abſolutely neceſſary to be done when they are about an Inch and an half high. When theſe Plants are removed, great Care ſhould be taken not to break or injure their Roots, as alſo to preſerve the Earth to their Roots: nor ſhould they be kept any Time out of the Ground; for if their Fibres are ſuffer'd to dry, they are very ſubject to mould, and periſh ſoon after.

The Soil in which I have found theſe Plants to thrive beſt, was compos'd in the following Manner; *viz.* one Load of freſh light Earth, one Load of rotten Cow-dung, with half a Load of Sea-ſand: Theſe were well mix'd together, and laid in an Heap ſix Months before it was uſed; in which Space it was turn'd ſeveral times, the better to incorporate the ſeveral Parts.

It muſt alſo be obſerv'd, that in tranſplanting theſe Plants, they ſhould never be put into Pots too large, in which they ſeldom thrive. The young Plants, when taken out of the Pots in which they were ſown, ſhould be planted each into a ſmall half-penny Pot fill'd with the above-mention'd Earth, and then plung'd into a moderate Hot-bed of Tanner's Bark, obſerving to water them frequently, tho' they ſhould not have too much given them at one Time: The Glaſſes ſhould alſo be raiſed, to admit freſh Air every Day, and in the Heat of the Day ſhould be ſhaded with Mats; for if they are too much expoſed to the Sun, they will perſpire ſo freely, as to have little Moiſture remaining in their Leaves, whereby they will hang, and appear very ſickly, as will alſo the tender Shoots, by which their Growth will be greatly retarded. As theſe Plants advance in Height, ſo ſhould they have a greater Proportion of freſh Air at all Times when the Weather is warm; and their Waterings ſhould be frequently repeated, tho' it muſt be perform'd with great Moderation, for too much Moiſture is very ſubject to rot the Roots, and when once the Roots are decay'd, it ſeldom happens that thoſe Plants are ever recover'd, tho' managed with all poſſible Skill and Care.

During the Winter-ſeaſon theſe Plants ſhould be placed in a Bark-ſtove, that the Fibres of the Roots may not be too much dry'd, (which often happens when the Pots are placed upon Shelves in a dry Stove) whereby the Top-ſhoots of the Plants are often decayed, and the Leaves are apt to turn brown and fall off, which is of very ill Conſequence to them; for if once the Leaves fall intirely off, the Plants are ſeldom recovered again ſo as to be beautiful.

This Stove ſhould be kept up to the temperate Heat, (mark'd on Mr. *Fowler's* Thermometers) with which they thrive better than in a greater Warmth; for if they are kept over-hot, they perſpire too freely, ſo that their Leaves will droop, and change their Colour. In this Situation they ſhould be water'd frequently; but it muſt be given them ſparingly, and the Water ſhould always be placed in the Stove twenty-four Hours before it be uſed, that it may acquire a Warmth nearly equal to the Temperature of Air in the Stove.

You muſt alſo clean their Leaves frequently from Filth, which they are ſubject to contract when ſhut up cloſe; as alſo many ſmall Inſects are harbour'd upon the Surfaces of the Leaves, which, if not carefully clean'd off, will greatly injure the Plants. The beſt Method to clean off theſe, is with a ſoft Woollen Cloth dipt in Water, with which you may eaſily waſh them off: but you ſhould be careful not to bruiſe their Leaves, nor to wet them too much, eſpecially in the Depth of Winter.

You ſhould alſo be careful, in placing them in the Stove, not to ſet them under the Branches of other Plants, nor too cloſe to them, whereby their Branches may intangle therewith, which will cauſe them to ſhed their Leaves, or at leaſt occaſion their diſcolouring; and in the Spring, when their Bloſſoms begin to appear, they muſt be more frequently watered, as alſo their Leaves and Branches often clean'd, which will cauſe their Leaves to look of a beautiful Green, and their Flowers to be ſtrong, and their Fruit will ſet the better.

In the Summer they muſt be continued in the Stove, with their Pots plung'd in Bark, (which ſhould not be too hot): but they muſt have a great Share of freſh Air in warm Weather, and the Glaſſes ſhould be ſhaded in the Heat of the Day; for they do not care to be too much expoſed to the direct Rays of the Sun, which occaſions their tender Shoots and Leaves to flag and hang down, and thereby retards the Growth of the Plants: You muſt alſo obſerve to ſhift them into freſh Earth whenever you find their Roots to ſhoot thro' the Holes at the Bottom of the Pots: but this will ſcarce happen oftener than twice a Year; ſo that I would adviſe the ſhifting them in *May*, and the Beginning of *Auguſt*, which are the propereſt Seaſons for this Work: but in the doing of it, you ſhould be careful to preſerve the Earth to their Roots, and only to pare off the Outſide of the Ball, cutting away all mouldy or decay'd Fibres; then put them into Pots one Size bigger than thoſe which they came out of, filling up the Pots with the before-mention'd Earth, obſerving to water and ſhade them, as the Heat of the Weather ſhall require: And if at theſe Times you mix a little new Bark in the Bed to add a freſh Heat thereto, before the Pots are plung'd therein, it will greatly facilitate their rooting again: but you muſt be careful not to make the Bed too hot. You ſhould alſo, in Summertime, refreſh all the Branches and Leaves of the Trees, by watering them gently with a fine-headed Watering-pot all over their Heads; and if in a very warm, gentle Shower of Rain, you draw off the Top Glaſſes of the Stove, and let them receive the Benefit thereof, it will be of great Service to them: but you muſt be careful not to expoſe them to hard Rains, or ſtrong Winds, which would prove very hurtful to them.

Theſe Directions, if carefully attended to, will be found ſufficient to inſtruct any Perſon in the Culture of this beautiful Plant; and altho' there may, perhaps, ſomething occur to them which is not here related, yet I believe it will rarely happen, but that the Appearances, be they from what Cauſe ſoever, may be found owing to ſome Neglect or contrary Practice to this here mentioned. But before I leave this Head, I cannot help mentioning another Method in which I have propagated this Plant; which is, by laying down ſome of their tender Shoots into Pots of Earth in the Spring of the Year, ſlitting them at a Joint, (as is practiſed in laying *Carnations*) obſerving to refreſh them frequently with Water, and in about three Months Time they will be rooted enough to tranſplant, when they ſhould be gently cut from the old Plant, and planted into ſeparate Pots, managing them as was directed for the ſeedling Plants.

There are ſome who have aſſerted, that this Plant will grow from Cuttings: but of all the different Trials which I have made, I could never obtain one Plant that way, tho' many times the Cuttings have remain'd freſh for ſeveral Months, and ſometimes have made ſmall Shoots; yet, upon taking them up, they have not had the leaſt Appearance of any Roots.

The fourteenth Sort of Jaſmines was formerly brought from *Malabar* in the *Eaſt Indies* into *Italy*, where it is now pretty common in the curious Gardens; but in *England* it is ſtill very rare. The fifteenth and ſixteenth Sorts were diſcovered by the late Dr. *Houſtoun* at *la Vera Cruz* in *America*, from whence he ſent Specimens and Seeds of both Kinds to *England*.

Theſe Plants may be propagated by Seeds or Layers; but as they do not produce Seeds in *Europe*, and they are rarely brought from the Countries of their natural Growth, ſo the only Method of propagating them is by Layers: Theſe Layers ſhould be laid down early in the Spring, at which Time the Pots ſhould be plunged into a moderate Hot-bed of Tanners-bark, obſerving to water them duly in hot Weather, as alſo to let them have a good Share of freſh Air. With this Management the Layers will be rooted in three or four Months, fit to tranſplant; when they ſhould be carefully taken up, and cut off from the old Plants, and each planted into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken new Root; after which Time they may be removed into the Stove, where they ſhould be kept warm during the Winter Seaſon; and they ſhould be frequently refreſhed with Water. In Summer theſe Plants ſhould have a large Share of freſh Air admitted to them in warm Weather, by opening of the Glaſſes of the Stove; but they ſhould never be ſet abroad in the open Air, for they are too tender to thrive abroad in this Climate, even in the hotteſt Seaſon of the Year. Theſe Plants alſo require a large Share of Moiſture in hot Weather, and their Leaves ſhould be frequently refreſhed with Water, and waſhed with a Sponge, to clear 'em from the Filth, which they are very ſubject to contract by remaining conſtantly in the Houſe.

With this Management theſe Plants will thrive and produce Plenty of Flowers every Year in *July* and *Auguſt*; and their Leaves remaining green thro' the Year, they make an agreeable Variety in the Stove, amongſt other tender exotic Plants.

The *Spaniſh* or *Catalonian* Jaſmine, as it is vulgarly called, is a Native of *America*, from whence I ſuppoſe it was brought to *Spain*; ſoon after the *Spaniards* had poſſeſſed themſelves of the South Continent of *America*, becauſe this Plant is not known to grow wild in any Part of *Europe*; but in many

Places in the *Spaniſh Weſt-Indies*, the Woods are full of it; as I have been informed by Mr. *Robert Millar*, Surgeon, who ſent over many Specimens of this Plant from them.

IBERIS, or SCIATICA-CRESS. *Vide* Lepidium.

IBISCUS, or MARSH-MALLOW. *Vide* Althæa.

ICACO, *American* Plum, *vulgò*.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of ſeveral Petals, which are placed in a circular Order; from whoſe Flower-cup ariſes the Pointal, which afterward becomes an oval ſoft fleſhy Fruit, incloſing a rough Stone of the ſame Form, in which is contained a round Kernel.

The *Species* are;

1. ICACO *fructu ex albo rubeſcente. Plum. Nov. Gen.* The Maiden Plum-tree.
2. ICACO *fructu nigro. Plum. Nov. Gen. American* Plum-tree.
3. ICACO *fructu purpureo. Plum. Nov. Gen.* Plum-tree with purple Fruit.
4. ICACO *fructu luteo. Houſt.* The yellow Plum-tree.

Theſe Trees are very common in *Jamaica, Barbadoes*, and ſeveral other Parts of *America*, where the Fruit is eſteemed by ſome of the Inhabitants, but by others it is thought to cauſe the dry Gripes. They uſually grow to the Height of ſixteen or eighteen Feet, and the laſt Sort doth often riſe to the Height of thirty Feet, and ſpreads into a great Number of Branches.

In *Europe* they are preſerved with other curious exotic Plants in the warmeſt Stoves; for they are too tender to live thro' the Winter, unleſs they are kept very warm. They are commonly propagated by ſowing of their Stones, in Pots fill'd with freſh light Earth, and plunged into a Hot-bed of Tanners-bark; obſerving to water them frequently, as alſo to cover the Glaſſes of the Hot-bed every Night, to preſerve a Warmth in the Bed. When the Plants begin to appear, they muſt be carefully weeded, and duly watered; and the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants, to prevent their being drawn up too weak. When theſe Plants are about three or four Inches high, they ſhould be carefully taken up, and each tranſplanted into a ſeparate Pot, filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to water them duly, as alſo to ſhade them from the Sun, until they have taken new Root; after which Time the Glaſſes of the Hot-bed ſhould be raiſed every Day to admit freſh Air to the Plants, in proportion to the Heat of the Seaſon: Theſe Plants require a pretty large Quantity of Water in hot Weather, and the Pots muſt be conſtantly kept clear from Weeds. In this Hot-bed the Plants may remain until *Michaelmas*, when they ſhould be removed into the Stove, and plunged into the Hot-bed of Tanners-bark, where they may enjoy a good Share of Heat. During the Winter Seaſon the Plants muſt be frequently watered, but they ſhould not have it in large Quantities, eſpecially in cold Weather, or when they have caſt off their Leaves. In Summer they ſhould have a large Share of freſh Air admitted to them in warm Weather, by opening the Glaſſes of the Stove; but theſe Plants are too tender to bear the open Air of this Country, even in the hotteſt Seaſon of the Year; ſo that they ſhould conſtantly remain in the Stove, and always ſhould be plunged into the Tan. As the Plants advance in their Growth, ſo they ſhould be ſhifted into larger Pots; but they will not require to be tranſplanted oftener than once a Year, which ſhould always be done the latter End of *March*, or the Beginning of *April*, juſt before the Plants put out their freſh Leaves.

If theſe Plants are carefully managed, according to the foregoing Directions, they will thrive very faſt, and in three or or four Years will produce Fruit, which I have ſometimes ſeen perfectly ripe in *England*; ſo that they deſerve a Place amongſt other tender exotick Plants, as a great Curioſity.

In *America* the Inhabitants propagate theſe Plants by Truncheons or large Branches, which if cut off and planted in the rainy Seaſons, take Root very ſoon, and in a Year or two become large Plants. They are often planted to make Hedges in *Jamaica* and *Barbadoes*, and are eſteemed very proper for that Purpoſe, being quick in Growth.

The Name *Icaco*, which Father *Plumier* has applied to this *Genus*, is the *American* Name, by which the *Creolians* called the Fruit: but of late Years the *Engliſh* have given them the Epithet of *Plums*, as being, in their Opinion, ſomewhat near our *European* Plums.

ICE is a hard, tranſparent Body, formed from ſome Liquor congealed or fixed.

Ice is ſaid to be the natural State of Water, which remains firm, and not liquid, when no external Cauſe acts upon it.

The true Cauſe of the Congelation of Water into *Ice*, ſeems to be the Introduction of frigorifick Particles into the Pores or Interſtices between the Particles of Water; and by that means getting ſo near them, as to be juſt within the Spheres of one another's Attractions, and then they muſt cohere into one ſolid or firm Body.

It may be wonder'd why *Ice* goes to the Top of the Water; for one would imagine, that being colder than flowing Water, it ought to be more condenſed, and conſequently heavier: But it is to be conſidered, that there are always ſome Bubbles of Air interſpers'd in *Ice*. It is certain, by the ſwimming of *Ice* upon Water, that it is ſpecifically lighter than the Water out of which it is made by freezing: And it is as certain, that this Lightneſs of *Ice* proceeds from thoſe numerous Bubbles that are produced in it by Congelation.

Water, when it is frozen into *Ice*, takes up more Space than it did before it was congeal'd. It is viſible, that the Dimenſions of Water are increas'd by freezing; its Particles being kept at ſome Diſtance the one from the other, by the Intervention of the frigorifick Matter.

And beſides, there are many little Volumes of Air included at ſeveral Diſtances, both in the Pores of the watery Particles, and in the Interſtices made by the ſpherical Figures. Now by the Inſinuation of theſe Cryſtals, the Volumes of Air are driven out of the watery Particles, and many of them uniting, form larger Volumes; theſe have thereby a greater Force to expand themſelves than when they are diſperſed, and ſo both inlarge their Dimenſions, and leſſen the ſpecifick Gravity of Water thus congealed into *Ice*.

It ſeems very probable, that Cold, and Freezing, and conſequently *Ice*, are produced by ſome Subſtance of a ſaline Nature floating in the Air; in that, Salts, and more eminently ſome particular ones, when mixed with *Ice* or *Snow*, do wonderfully increaſe the Force and Effects of Cold.

It is alſo viſible, that all ſaline Bodies do cauſe a Stiffneſs and Frigidity into thoſe Bodies into which they enter.

It is manifeſt, by obſerving Salts by Microſcopes, that the Figures of ſome Salts, before they ſhoot into Maſſes, are then double Wedge-like Particles, which have Abundance of Surface in reſpect to their Solidity; and this is the Reaſon why they ſwim in Water, when once they are raiſed in it, altho' they are ſpecifically heavier: Theſe ſmall Points of Salts getting into the Pores of the Water, whereby they are, in ſome meaſure, ſuſpended in the Winter, when the Heat of the Sun is not ordinarily ſtrong enough to diſſolve the Salts into a Fluid, to break their Points, and to keep them in perpetual Motion; which being leſs diſturb'd, are more at Liberty to approach one another; and by ſhooting into Cryſtals, of the Form above mentioned, do, by their Extremities, inſinuate themſelves into the Pores of Water, and by that means freeze it into a ſolid Form call'd *Ice*.

As to Thawing, the Reaſon ſeems to be, that Heat afterwards ſeparating them, and putting thoſe ſaline or frigorifick Particles into Motion, breaks this Union, and ſeparates the Particles ſo far from one another, that they get out of the Diſtance of the attracting Force, and into the Verge of the repelling Force, and then the Water reſumes its fluid Form.

Monſ. *Mariotte*, in his Treatiſe of *Hydroſtaticks*, gives the ſubſequent Account of what happens to Water in freezing, which he diſcover'd by the following Experiment.

Having fill'd a cylindric Veſſel of about ſeven or eight Inches high, and ſix Inches diameter, within two Inches of the top, with cold Water, he expoſed it to the open Air, in a great Froſt, and obſerved exactly the whole Progreſs of the freezing of it.

The firſt Congelation was in the upper Surface of the Water, in little long Water-ſhoots or Laminæ, which were jagged like a Saw, the Water between them remaining ſtill unfrozen, though the reſt of the Surface was already frozen to the Thickneſs of more than two Lines; he obſerved that ſeveral Bubbles of Air were formed in the *Ice*, that began to fix on the Bottom and Sides of the Veſſel, ſome would riſe up, and others remained intangled in the *Ice*, which made him imagine that theſe Bubbles taking up more Space in the Water, than when their Matter was, as it were, diſſolved in it, they puſhed up a little Water through the Hole at the Top, after the ſame manner that new Wine works out at the Bung-hole of a Veſſel when it begins to heat; and the little Water that ouzed out at this little Hole in the *Ice*, ſpreading itſelf upon the upper Surface of the Water, which was already frozen, became *Ice* alſo, and there began to form an Hill of *Ice* ; and that Hole continuing open, by reaſon of the Water which paſſed ſucceſſively through it, being puſhed up by the new Bubbles which formed themſelves in the *Ice*, which continued to increaſe about the Sides and Bottom of the Veſſel ; he obſerv'd that the upper Surface of the Water was frozen above an Inch thick towards the Edges of the Veſſel, and above an Inch and an half round about the little Hole, before the Water that was contained in it, as in a Pipe, became frozen ; but at laſt it was frozen : Then the middle of the Water remaining unfrozen, and the Water which was compreſſed by the new Bubbles, which formed themſelves for two or three Hours, having no Vent at the little Hole, the *Ice* broke at once towards the Top, by the Spring of the included Air.

He try'd the Experiment a ſecond time ; and when the *Ice* was about two Inches thick, he warmed the Sides of the Veſſel to melt the Outſide of the *Ice*, and by that means drew it whole out of the Veſſel, without ſpilling the Water that was contained in the Middle of the *Ice* ; then expoſing this *Ice* to the open Air, that the reſt of the Water might freeze, it broke three or four Hours after, and he found a Cell in the Middle of about one Inch and an half diameter, containing the Water that remained ſtill unfrozen, which ran out upon the breaking of the *Ice*.

He made the Experiment the third time ; and having taken out the *Ice*, as before, with a large Pin he made a Hole in the *Ice*, over the little Pipe or Channel above-mentioned, where the *Ice* was an Inch higher than any where elſe, by reaſon of the Water which had ouzed out at the little Hole, and was there frozen ; and as ſoon as he drew out the Pin, ſome Water ſpouted out at the Hole, and then the Hole was frozen up again ; ſtill as the Hole was frozen up, he prick'd the *Ice*, 'till all the Water was frozen, then he expoſed that Lump of *Ice* to the Air for a whole Night without its breaking : which plainly ſhew'd, that, in the foregoing Experiments, the Spring of the Air-bubbles was the only Reaſon of the breaking of the *Ice*.

The Middle of the frozen Lump had about as much Air in it as *Ice* ; but there were but few Bubbles towards the Outſide, in Proportion to the *Ice*.

If by boiling the Water you drive the Aerial Matter out of it, before you ſet it out to freeze, you will have *Ice* two or three Inches thick, without any viſible Bubbles, and ſo tranſparent, as to be fit to burn by the Sun's Rays, as Convex Glaſſes do.

JET D'EAU is a *French* Word, which ſignifies a *Fountain* that caſts up Water to any conſiderable Height in the Air.

Monſ. *Mariotte*, in his Treatiſe of *Hydroſtaticks*, ſays, That a *Jet D'eau* will never riſe ſo high as its Reſervatory ; but always falls ſhort of it by a Space which is in a ſubduplicate Ratio of that Height : And this he proves by ſeveral Experiments ; That tho' *Jets* ought to riſe to the Height of the Reſervatories, yet the Friction of the Sides of the Ajutages, and the Reſiſtance of the Air, are the Cauſes that in *Jets* that have very high Reſervatories, the Height of the *Jets* does not come up to that of the Reſervatory by a great deal.

He adds ; That if a greater branches out in many ſmaller ones, or is diſtributed through ſeveral *Jets*, the Square of the Diameter of the main Pipe muſt be proportion'd to the Sum of all the Expences of its Branches : That if the Reſervatory be 52 Feet high, and the Ajutage half an Inch in diameter, the Pipe ought to be three Inches in diameter.

He ſays ; That the Beauty of *Jets* of Water conſiſts in their Uniformity and Tranſparency at the going out of the Ajutage, and ſpreading but very little, and that to the higheſt Part of the *Jet*.

That the worſt Sort of Ajutages are thoſe that are Cylindrical ; for they retard very much the Height of the *Jets* ; the Conic retard it leſs : but the beſt way is, to bore the Horizontal Plane, which ſhuts the Extremity of the Pipe or Conduit, with a ſmooth and poliſh'd Hole ; taking care that the Plate be perfectly plain, poliſh'd, and uniform.

ILEX [takes its Name of אלה, Heb, *an Oak*, becauſe this Tree is a Species of Oak] the Ever-green Oak.

The *Characters* are ;

The Leaves are, for the moſt part, indented or ſinuated, (and in ſome the Edges of the Leaves are prickly) and are Evergreen : It hath amentaceous Flowers, which are produced at remote Diſtances from the Fruit, on the ſame Tree : The Fruit is an Acorn, *like the common* Oak.

The *Species* are ;

1. Ilex *folio anguſto non ſerrato.* C. B. P. The Olive-leaf'd Ever-green Oak.
2. Ilex *folio oblongo ſerrato.* C. B. P. Narrow-leaf'd Ever-green Oak, with ſerrated Leaves.
3. Ilex *folio Agrifolii. Bot. Monſp.* Holly-leaf'd Ever-green Oak.
4. Ilex *folio rotundiore molli, modiceque ſinuato, ſive ſmilax Theophraſti.* C. B. P. The Ever-green Oak, with round, ſmooth, ſinuated Leaves.
5. Ilex *aculeata cocciglandifera.* C. B. P.

There are ſeveral other Varieties of theſe Trees, which differ in the Shape of their Leaves ; ſome being long and ſmooth, others are rounder, and have many Prickles upon their Edges ; and ſome have their Leaves ſinuated and waved like thoſe of the *Holly* : but as theſe are only ſeminal Variations, and will ariſe from Seeds taken from the ſame Tree, ſo it is not worth troubling myſelf or the Reader to enumerate their ſeveral Diſtinctions in this Place ; ſince thoſe above mentioned are the moſt common Varieties ; and all the other Differences will be nearly allied to one or other of the four firſt Sorts.

Theſe Trees are propagated by ſowing their Seeds ; the beſt Seaſon for this Work is in the Beginning of *March* : but then, as the Acorns are ripe in Autumn, they ſhould be preſerved either in Sand or dry Earth until the Spring, otherwiſe they will loſe their growing Faculty ; which is commonly the Caſe with thoſe brought annually from *Genoa*, ſcarce one Seed in fifty of them ever riſing ; however, ſince we have many large Trees now in *England* which produce good Seeds, we need not ſend to *Italy* for them : But were I to adviſe, I ſhould much rather have them from *Portugal* than *Italy* ; for the Voyage being much ſhorter, they are generally brought from thence in very good Condition.

The Manner in which I would adviſe their being ſown, is, if for large Quantities, in Drills at about two Feet Diſtance ; but for a ſmall Parcel, they muſt be ſown in Rows on a Bed much nearer.

The Ground in which theſe Seeds are ſown, ſhould be well dug and cleanſed from the Roots of all noxious Weeds, *&c.* and levell'd even, and the great Clods broken ; then draw the Rills with a Hough in a ſtrait Line (as is practiſed in the ſowing of *Kidney-beans*) about two Inches deep, laying the Acorns therein two or three Inches aſunder ; then draw the Earth over them with the Head of a Rake, obſerving that none of them are left uncovered, which would intice the Vermin to attack your Acorns, eſpecially the Mice, whereby your Seminary will be greatly injured, if not wholly deſtroy'd.

In the Middle of *April* the young Plants will appear above-ground ; you muſt then clear the Ground from Weeds, which would ſoon overſpread and deſtroy the Plants ; which muſt conſtantly be obſerv'd, eſpecially while they are young. The firſt Year from Seed they will make but ſmall Progreſs, but afterwards they will make Amends by their quick Growth, (eſpecially if they agree with the Soil) ; in *March* following you muſt gently dig up the Ground between the Rows of Plants, in order to deſtroy the Weeds, and to render it light for the Roots to ſtrike out on each Side, which will greatly promote the Growth of the Plants : but in doing of this, you ſhould be very careful not to diſturb the Roots of the Plants, which would greatly injure them : In this Place they may remain until the ſecond Spring after ſowing, when, in the Beginning of *April*, you ſhould take up the Plants where they are too cloſe, and tranſplant them where they are deſigned to remain. But as theſe Trees are ſubject to have Tap-roots, ſo they are very difficult to be removed ; you muſt therefore obſerve to take them up with a good Ball of Earth to their Roots, and carry them immediately to the Places where they are to be planted, placing them into Holes which ſhould be well prepared before ; and if the Weather be dry, you ſhould pour a good Quantity of Water into the Holes about the Earth like Pap ; then placing the Plants therein, you ſhould fill up the Holes about their Roots with the like pappy Earth ; and then lay ſome Mulch upon the Surface of the Ground round their Roots, and give them ſome Water to ſettle the Earth to their Roots : And if the Seaſon ſhould continue dry, you muſt repeat watering them once a Week, which Water ſhould be poured all over the Heads of the Plants : but by no means give them too much, which, as I have already ſaid, deſtroys more new-planted Trees than any other Accident whatever.

But in taking up theſe Plants from the Seminary, you ſhould be careful not to injure the Roots of thoſe left remaining : nor muſt the Ground about their Roots remain long open ; but as ſoon as you have taken up thoſe that are to be tranſplanted, the whole Ground ſhould be ſlightly dug and levell'd even: The Diſtance theſe Plants ſhould be left in the Rows where they were ſown, ought to be two Feet, which will allow them Room enough to grow three or four Years longer, at which Time they muſt be tranſplanted, (eſpecially all ſuch as are not deſign'd to remain for good): but you ſhould, the precedent Spring, dig near the Roots of thoſe which are to be removed, and cut underneath them with your Spade, to take off the Tap-roots: but you muſt obſerve not to cut them too cloſe to the Plants, leſt you deſtroy them; this will occaſion their puſhing out many Fibres, whereby the Earth will be better preſerved to their Roots when they are tranſplanted, and there will be leſs Danger of their not growing.

It has been directed by moſt People who have written on theſe Trees, to ſow the Acorns in Pots, and when the Plants have grown two or three Years therein, to ſhake them out of the Pots, preſerving all the Earth about them, and to plant them where they are to remain: which is a very good Method for ſmall Quantities; but the Trouble of this in large Plantations would be too great, eſpecially if we conſider that theſe Plants, while in Pots, will require conſtantly to be water'd in dry Weather; otherwiſe they will be ſubject to fail, or at leaſt will make but poor Progreſs. And altho' it is generally thought very hazardous to remove theſe Trees, yet I believe, if great Care be taken, firſt, to obſerve the juſt Seaſon, which is in the Beginning of *April*; ſecondly, to preſerve as much Earth to their Roots as poſſible; and, thirdly, not to keep them long above ground, the removing of theſe Trees will not be found ſo dangerous as moſt People imagine.

And I am convinced, that Trees of ſeven or eight Years Growth, are in leſs Danger of ſuffering by Tranſplantation, than thoſe that are much younger; for in the Year 1727, I removed many of theſe Trees which were five or ſix Feet high, and though they had not been ſo well managed in the Place where they were rais'd, as might be wiſh'd, yet but one of the whole Number fail'd, notwithſtanding the Seaſon prov'd dry for near a Month after.

Theſe Trees are by many People greatly eſteem'd for Hedges to ſurround Wilderneſs Quarters; but they are ſubject to grow too large for that Purpoſe, becauſe we ſhould never hide the Tops of the Trees in ſuch Places from the Sight; for they are, if rightly diſpoſed in the Quarters, vaſtly more agreeable to the Eye, than the fineſt ſhear'd Hedge in the World; but they may do well enough for a large Fence, to obſtruct the Sight, or to defend a new Plantation of tender Trees; for which Purpoſe the Acorns ſhould be ſown in the Place where the Hedge is deſign'd; and when the Plants are come up, they ſhould be thinned, where they are to cloſe; and if the Ground is kept clear from Weeds, and every Spring dug about the Plants, they will ſoon form a good Hedge: But you ſhould obſerve not to let them grow too much in Height before the bottom part of the Hedge is well ſtrengthen'd, which would occaſion its bending, and the Branches would be ſubject to be diſplaced with ſtrong Winds, or great Snows, and thereby become very unſightly: But if they are regularly train'd up, they will make a good thick Hedge from the Ground to the Height of forty Feet, and that in leſs Time than any other Tree whatever.

The Soil in which theſe Trees thrive beſt, is a hazelly Loam, not too ſtrong, nor over-light, in which they will grow to a large Size, and reſiſt the ſevereſt Cold of our Climate; and retaining their Leaves all the Winter, do afford an agreeable Proſpect in that Seaſon: But they ſhould by no means be planted near ſuch Walks, or other Parts of the Garden, as are intended to be kept clean; for in the Month of *April*, when they caſt their old Leaves, they make a great Litter, and are apt to blow about with the Wind, and become very troubleſome; and in *June*, when their Male Flowers fall off, they occaſion no leſs Trouble to clean them up daily in ſuch Places; and in the pleaſanteſt Seaſon of the Year they are the moſt unſightly Trees in a Garden, the old Leaves decaying at that Seaſon, and falling off; and the Male Flowers, which are generally in great Plenty, are then produced, which renders it not ſo valuable in Places much frequented: But for larger Plantations, at a remote Diſtance from the Habitation, ſo as to be juſt within the View, they make a very handſom Appearance, eſpecially in the Winter-ſeaſon.

The Wood of this Tree is accounted very good for many Sorts of Tools and Utenſils, as *Mallet-Heads*, *Mall-Balls*, *Chairs*, *Wedges*, *Beetles*, *Pins*, &c. as alſo for *Paliſado's*; and affords the moſt durable *Charcoal* in the World, and is the common Fuel in the Southern Parts of *France* and *Italy*.

The *Kermes*, or *Holm-Oak* is of a much lower Stature than the former Sorts, and ſeldom grows to the Height of a Tree: This, tho' a Native of the warmeſt Parts of *France*, yet will endure the Cold of our Climate in the open Air. It may be propagated in the ſame Manner as the former, and deſerves a Place amongſt other Shrubs of low Growth, for its Curioſity, as being the Plant upon which the *Kermes* are bred; the Hiſtory of which may be ſeen at large in *Garidel's Hiſtory of the Plants which grow in* Provence, it being too long to be inſerted here.

IMPERATORIA, Maſterwort.

The *Characters* are;

It is planted with a Roſe and umbellated Flower, conſiſting of ſeveral Petals, which are ſometimes heart-ſhaped, and ſometimes intire, ranged in a Circle, and reſting on the Empalement; which afterward becomes a Fruit, compoſed of two Seeds, which are plain, almoſt oval, gently ſtreaked and bordered, and generally caſting their Cover. To theſe Marks muſt be added, that their Leaves are winged, and pretty large.

The *Species* are;

1. IMPERATORIA *major*. *C. B. P.* Common Maſterwort.
2. IMPERATORIA *Pyrenaica tenuifolia*. *Tourn.* Narrow-leav'd *Pyrenean* Maſterwort.
3. IMPERATORIA *Alpina maxima*. *Tourn.* Greateſt Maſterwort of the *Alpes*.

The Root of the firſt Species is uſed in Medicine; it has a very hot acrid Taſte, and is eſteemed alexipharmic, ſudorific, and a great Attenuater and Opener.

This Sort is cultivated in Gardens to ſupply the Markets. It may be propagated either by Seeds, or parting of the Roots: If you would propagate it by Seeds, they ſhould be ſown in Autumn, ſoon after they are ripe, on a Bed or Border of light Earth, in a ſhady Situation; obſerving not to ſow the Seeds too thick, nor ſhould they be covered too deep. In the Spring the Plants will appear, when they ſhould be carefully weeded, and if the Seaſon ſhould prove very dry, they ſhould be now and then refreſhed with Water, which will greatly promote the Growth of the Plants; towards the Beginning of *May*, if you find the Plants come up too cloſe together, you ſhould prepare a moiſt ſhady Border (and thin the Plants carefully, leaving them about four Inches aſunder); and plant thoſe which you draw up, into the Border about ſix Inches apart every Way, being careful to water them duly, if the Seaſon ſhould prove dry, until they have taken Root; after which Time, theſe Plants (as alſo thoſe remaining in the Seed-beds) will require no other Culture but to keep them clear from Weeds, which may be eaſily effected by houghing the Ground between the Plants now and then in dry Weather, which will deſtroy the Weeds, and by ſtirring of the Ground, will be of great Service to the Plants. The following Autumn, theſe Plants ſhould be tranſplanted where they are deſigned to remain; which ſhould be in a rich moiſt Soil, and a ſhady Situation; where they will thrive much better, than if too much expoſed to the Sun, or in a dry Soil; for they delight in Shade and Moiſture; ſo that where theſe are wanting, the Plants will require a conſtant Supply of Water in dry Weather, otherwiſe they will thrive but ſlowly. The Diſtance which theſe Plants ſhould be placed, muſt not be leſs than twenty Inches, or two Feet every Way; for where they like their Situation, they will ſpread and increaſe very much. When theſe Plants are rooted, they will require no other Culture, but to keep them clear from Weeds; and in the Spring before they ſhoot, the Ground ſhould be every Year gently dug between the Plants; in doing of which great Care ſhould be had, not to cut or bruiſe their Roots: Theſe Plants, with this Management will continue ſeveral Years, and will produce Seeds in plenty.

If you would propagate theſe Plants by Off-ſets, their Roots ſhould be parted at *Michaelmas*, and planted in a ſhady Situation, at the ſame Diſtance as has been directed for the ſeedling Plants, obſerving to water them until they have taken Root; after which Time they muſt be managed as the Seedlings.

The other two Sorts are preſerved in botanic Gardens for the ſake of Variety; but as they are not uſed in Phyſic, nor are ornamental Plants, ſo they are ſeldom allowed a Place in other Gardens. Theſe two Sorts may be propagated in the ſame Manner as the former, and are both equally hardy; ſo that they may be placed in any ſhady moiſt cold Situation, where they will thrive very well.

INARCHING, is a Method of *Grafting*, which is commonly call'd *Grafting by Approach*. This Method of *Grafting* is uſed, when the Stock you intend to graft on, and the Tree from which you would take the Graft, ſtand ſo near, (or can be brought ſo near) that they may be joined together. The Method of performing it is as follows: Take the Branch you would inarch, and having fitted it to that Part of the Stock where you intend to join it, pare away the Rind and Wood on one Side about three Inches in Length. After the ſame Manner cut the Stock or Branch in the Place where the Graft is to be united, ſo that they may join equally together, that the Sap may meet; then cut a little Tongue upwards in the Graft, and make a Notch in the Stock to admit it; ſo that when they are join'd, the Tongue will prevent their ſlipping, and the Graft will more cloſely unite with the Stock. Having thus placed them exactly together, you muſt tie them with ſome Baſs, or other ſoft Tying; then cover the Place with grafting Clay, to prevent the Air from entering to dry the Wound, or the Wet from getting in to rot the Stock: You ſhould alſo fix a Stake into the Ground to which that Part of the Stock, as alſo the Graft, ſhould be faſten'd, to prevent the Wind from breaking them aſunder, which is often the Caſe when this Precaution is not obſerved.

In this Manner they are to remain about four Months, in which Time they will be ſufficiently united, and the Graft may then be cut from the Mother-tree, obſerving to ſlope it off cloſe to the Stock: And if at this Time you cover the join'd Parts with freſh grafting Clay, it will be of great Service to the Graft.

This Operation is always perform'd in *April* or *May*, that the Graft may unite with the Stock before the ſucceeding Winter, and is commonly practis'd upon *Oranges*, *Myrtles*, *Jaſmines*, *Wall-nuts*, *Firs*, *Pines*, and ſeveral other Trees, which will not ſucceed by common Grafting or Budding. But altho' I have mentioned *Orange-trees* among the reſt, yet I would by no means adviſe this Practice where the Trees are deſigned to grow large, which, in this Method they rarely ever will do: And it is chiefly practis'd upon thoſe Trees only as a Curioſity, to have a young Plant with Fruit upon it, in a Year or two from Seed, by inarching a bearing Branch into a young Stock, whereby it is effected: Yet theſe Plants are ſeldom long-liv'd.

INDIGO. *Vide* Anil.

INGA.

This is the *American* Name of the Plant, for which we have no *Engliſh* Name at preſent.

The *Characters* are;

It hath a funnel-ſhaped Flower, conſiſting of one Leaf, whoſe Tube is furbelowed; from the Flower-cup ariſes the Pointal, fixed like a Nail in the Hinder-part of the Flower, which afterward becomes a ſoft fleſhy Pod; in which are contained many irregular Seeds incloſed in a ſweet Pulp.

We know but one *Species* of this Plant, *viz.*

INGA *flore albo fimbriato, fructu dulci. Plum. Nov. Gen.* Inga with a white furbelowed Flower, and a ſweet Fruit.

This Tree is very common on the North Side of the Iſland of *Jamaica*, at *La Vera Cruz*, and in ſeveral other Parts of the *Spaniſh Weſt-Indies*; where it riſes to the Height of ſixteen or twenty Feet, and ſends forth many crooked ſtraggling Branches, which hang downward, and are covered with a whitiſh Bark. The Flowers come out at the Ends of the Branches which are ſucceeded by the Pods, which are ſometimes eaten by the Negroes.

In *Europe* this Plant is preſerved by thoſe Perſons who are curious in exotic Plants; it is propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving frequently to water them; and if the Nights are cold, the Glaſſes of the Hot-bed ſhould be covered as ſoon as the Sun goes off, in order to preſerve a gentle Warmth in the Bed. When the Plants are come up two Inches high, they ſhould be carefully tranſplanted into ſeparate Pots, filled with light rich Earth, and then plunged into the Hot-bed again, being careful to ſhade them from the Sun until they have taken new Root; after which Time they muſt be plentifully watered; and in hot Weather the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants, to prevent their being drawn up too weak. At *Michaelmas* theſe Plants muſt be removed into the Stove, and plunged into the Tan in the warmeſt Part of the Bed. During the Winter-ſeaſon theſe Plants muſt be kept very warm, and they muſt be frequently refreſhed with Water; but it muſt not be given to them in too large Quantities in cold Weather; in the Summer they muſt be plentifully watered, and in hot Weather they ſhould have a large Share of freſh Air, by opening of the Glaſſes of the Stove; but they muſt not be removed out of the Stove, for they are too tender to endure the open Air of this Country, in the warmeſt Part of the Year. When the Plants have filled the Pots with their Roots, they ſhould be tranſplanted into larger, and their Roots ſhould be then carefully trimmed: With this Management the Plants will thrive, and in a few Years produce Flowers, ſo will add to the Variety amongſt other tender exotic Plants.

INOCULATING, *or* Budding: This is commonly practiſed upon all Sorts of Stone-Fruit; in particular, ſuch as *Peaches*, *Nectarines*, *Cherries*, *Plums*, &c. as alſo upon *Oranges* and *Jaſmines*, and is preferable to any Sort of Grafting for moſt Sorts of Fruit. The Method of performing it is as follows: You muſt be provided with a ſharp Pen-knife, having a flat Haft, (the Uſe of which is to raiſe the Bark of the Stock, to admit the Bud) and ſome ſound Baſs-mat, which ſhould be ſoak'd in Water, to increaſe its Strength, and make it more pliable; then having taken off the Cuttings from the Trees you would propagate, you ſhould chuſe a ſmooth Part of the Stock about five or ſix Inches above the Surface of the Ground, if deſign'd for Dwarfs; but if for Standards, they ſhould be budded ſix Feet above-ground: Then with your Knife make an horizontal Cut croſs the Rind of the Stock, and from the Middle of that Cut make a Slit downwards about two Inches in Length, ſo that it may be in the form of a T: But you muſt be careful not to cut too deep, leſt you wound the Stock: Then having cut off the Leaf from the Bud, leaving the Foot-ſtalk remaining, you ſhould make a croſs Cut about half an Inch below the Eye, and with your Knife ſlit off the Bud, with part of the Wood to it, in form of an Eſcutcheon: This done you muſt with your Knife pull off that part of the Wood which was taken with the Bud, obſerving whether the Eye of the Bud be left to it, or not; (for all thoſe Buds which loſe their Eyes in ſtripping, ſhould be thrown away, being good for nothing): Then having gently rais'd the Bark of the Stock with the flat Haft of your Pen-knife clear to the Wood, you ſhould thruſt the Bud therein, obſerving to place it ſmooth between the Rind and the Wood of the Stock, cutting off any part of the Rind belonging to the Bud, which may be too long for the Slit made in the Stock; and ſo having exactly fitted the Bud to the Stock, you muſt tie them cloſely round with Baſs-mat, beginning at the Under-part of the Slit, and ſo proceed to the Top, taking Care that you do not bind round the Eye of the Bud, which ſhould be left open.

When your Buds have been inoculated three Weeks, or a Month, you will ſee which of them have taken; thoſe of them which appear ſhrivelled and black, being dead; but thoſe which remain freſh and plump, you may depend are join'd: And at this Time you ſhould looſen the Bandage; which, if not done in Time, will pinch the Stock, and greatly injure, if not deſtroy the Bud.

The *March* following you muſt cut off the Stock about three Inches above the Bud, ſloping it, that the Wet may paſs off, and not enter the Stock: To this Part of the Stock left above the Bud, it is very proper to faſten the Shoot which proceeds from the Bud, and would be in danger of being blown out, if not prevented; but this muſt continue on no longer than one Year; after which, it muſt be cut off cloſe above the Bud, that the Stock may be cover'd thereby.

The Time for *Inoculating*, is from the Middle of *June* until the Middle of *Auguſt*, according to the Forwardneſs of the Seaſon, and the particular Sorts of Trees; which may be eaſily known, by trying the Buds whether they will come off well from the Wood. But the moſt general Rule is, when you obſerve the Buds form'd at the Extremity of the ſame Year's Shoots, which is a Sign of their having finiſh'd their Spring Growth.

The firſt Sort commonly inoculated is the *Apricot*; and the laſt the *Orange-tree*, which ſhould never be done until the Middle of *Auguſt*. And in doing of this Work, you ſhould always make choice of Cloudy Weather; for if it be done in the Middle of the Day in very hot Weather, the Shoots will perſpire ſo faſt, as to leave the Buds deſtitute of Moiſture. Nor ſhould you take off the Cuttings from the Trees long before they are uſed: but if you are oblig'd to fetch your Cuttings from ſome Diſtance, as it often happens, you ſhould then be provided with a Tin Inſtrument, having a Socket about ten Inches long, and a Cover to the Top, which muſt have five or ſix Holes; in this Socket you ſhould put as much Water as will fill it about two or three Inches high, and place your Cuttings therein in an upright Poſition, ſo that that Part which was cut from the Tree may be ſet in the Water, and ſo faſten down the Cover to keep out the Air; and the Holes in the Cover will be ſufficient to let the Perſpiration of theſe Branches paſs off; which, if pent in, would be very hurtful to them: And you muſt be careful to carry it upright, that the Water may not reach to the Buds; for it is a very wrong Practice in thoſe who throw their Cuttings all over in Water, which ſo ſaturates the Buds with Moiſture, that they have no attractive Force left to imbibe the Sap of the Stock, whereby they very often miſcarry.

But before I leave this Head, I beg Leave too bſerve, that tho' it is the ordinary Practice to diveſt the Bud of that Part of the Wood which was taken from the Shoot with it; yet, in many Sorts of tender Trees, it is beſt to preſerve a little Wood to the Bud, without which they often miſcarry. The not obſerving this, has often occaſioned ſome People to imagine that ſome Sorts of Trees are not to be propagated by *Inoculation*; whereas, if they had perform'd it in this Method, they might have ſucceeded, as I have ſeveral Times experienced.

INTYBUS. *Vide* Endivia.

JONQUIL. *Vide* Narciſſus.

JONTHLASPI, Treacle Muſtard.

The *Characters* are;

It hath a Flower conſiſting of four Leaves, which are placed in Form of a Croſs; out of whoſe Flower-cup riſes the Pointal, which afterward becomes a Fruit, which is flat, round, and ſhaped like a Buckler, having but one Cell, in which is contained a flat round Seed.

The *Species* are;

1. JONTHLASPI *luteo flore, incanum montanum diſcoides. Col.* Hoary Mountain Treacle Muſtard, with a yellow Flower.
2. JONTHLASPI *minimum ſpicatum lunatum. Col.* The ſmalleſt ſpiked Treacle Muſtard.
3. JONTHLASPI *orientale, fructu echinato. Tourn. Cor.* Eaſtern Treacle Muſtard, with a prickly Fruit.

The firſt Sort is found in Plenty upon the Mountains near the *Tiber*; the ſecond Sort grows wild about *Montpelier*, as alſo in the Fields near *Niſmes*, and other Places in the South of *France*; likewiſe in *Spain* and *Italy*: But the third Sort was diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the *Royal Garden* at *Paris*.

All theſe Plants are annual, ſo muſt be ſown every Spring, on a Bed or Border of freſh light Earth; and when the Plants are come up, they ſhould be carefully weeded or houghed, and where they are too cloſe, they ſhould be thinned, leaving them about four or five Inches apart; after this they will require no other Care but to keep them clear from Weeds. In *June* they will flower, and their Seeds will ripen in *Auguſt*, which, if permitted to ſcatter, will come up, and ſtand thro' the Winter; and theſe autumnal Plants will flower early the following Spring. All theſe Sorts ſhould be ſown in the Places where they are deſigned to remain; for they do not ſucceed, if they are tranſplanted. They are all very ſmall Plants, ſeldom riſing above four or five Inches high, ſo do not make any Figure in a Garden; for which Reaſon they are ſeldom propagated, but in botanick Gardens for the ſake of Variety.

IRIS, [Ἶρις, *a Rainbow*] Fleur-de-Lys.

The *Characters* are;

It hath an oblong, fleſhy, creeping Root: The Flower conſiſts of ſix Leaves, three of which are bifid, and ſtand erect; the other three are reflexed: Upon the Under-part of the arched Leaves is placed a Congeries of Hairs reſembling a Beard. From the very Bottom ariſe the Male Stamina, carefully defended by a hollow Caſe of Petals. The Flower grows to the Apex of the Ovary, which ſends forth theſe Beards and Caſe-like Tubes; and hence it appears like a nine-leav'd Flower.

The *Species* are;

1. IRIS *purpurea, ſive vulgaris. Park. Par.* Common purple *Fleur-de-Lys.*
2. IRIS *hortenſis pallide cærulea. C. B.* Pale-blue Garden *Fleur-de-Lys.*
3. IRIS *hortenſis alba Germanica. C. B.* White Garden *German Fleur-de-Lys.*
4. IRIS *alba Florentina. C. B.* White *Florentine Fleur-de-Lys.*
5. IRIS *Dalmatica major. C. B.* Greater *Fleur-de-Lys* of *Dalmatia.*
6. IRIS *Suſiana, flore maximo ex albo nigricante. C. B.* The *Chalcedonian Iris*, with a large black and white Flower.
7. IRIS *latifolia Pannonica, colore multiplici. C. B.* Broad-leaf'd *Hungarian Fleur-de-Lys*, with a many-colour'd Flower.
8. IRIS *Illyrica, flore majore. Tourn. Fleur-de-Lys* of *Illyricum*, with a large Flower.
9. IRIS *ſativa lutea. C. B. P.* Yellow Garden *Fleur-de-Lys.*
10. IRIS *lutea variegata. Cluſ.* Yellow variegated *Fleur-de-Lys.*
11. IRIS *latifolia, candida, purpureis venis diſtincta. C. B.* Broad-leaf'd *Fleur-de-Lys*, with a white Flower ſtriped with purple.
12. IRIS *humilis minor, flore purpureo. Tourn.* Dwarf purple *Fleur-de-Lys.*
13. IRIS *anguſtifolia maritima major. C. B.* Greater narrow-leaf'd Sea *Fleur-de-Lys.*
14. IRIS *anguſtifolia maritima minor. C. B.* Leſſer narrow-leaf'd Sea *Fleur-de-Lys.*
15. IRIS *anguſtifolia minor Pannonica, ſive verſicolor. Cluſ.* Small variable narrow-leaf'd *Fleur-de-Lys* of *Hungary.*
16. IRIS *humilis minor anguſtifolia, flore variegato.* Dwarf narrow-leaf'd *Fleur-de-Lys*, with a variegated Flower.
17. IRIS *ſylveſtris, quam Xyrim vocant. Plin. Raii Syn.* Stinking Gladdon, *or* Gladwyn.
18. IRIS *hortenſis latifolia. C. B. P.* Broad-leav'd Garden *Fleur-de-Lys.*
19. IRIS *latifolia minor alba, oris cæruleis. Suvert.* Small broad-leav'd *Fleur-de-Lys*, with white Flowers, having blue Borders.
20. IRIS *latifolia minor alba, oris dilute purpureis. H. R. Par.* Leſſer broad-leav'd *Fleur-de-Lys*, with white Flowers with pale purple Borders.
21. IRIS *Aſiatica cærulea polyanthos. C. B. P.* Many-flower'd blue *Aſiatic Fleur-de-Lys.*
22. IRIS *Aſiatica purpurea. C. B. P.* Purple *Aſiatic Fleur-de-Lys.*
23. IRIS *peregrina ſubrubens inodora. C. B. P.* Reddiſh foreign *Fleur-de-Lys*, without ſmell.
24. IRIS *peregrina, odore oxyacanthæ. C. B. P.* Foreign *Fleur-de-Lys*, ſmelling like Haw-thorn.
25. IRIS *Byzantina purpuro-cærulea. C. B. P.* Purple blue *Fleur-de-Lys* of *Conſtantinople.*
26. IRIS *Damaſcena polyanthos. C. B. P.* Many-flower'd *Fleur-de-Lys* of *Damaſcus.*
27. IRIS *latifolia Germanica, odore ſuavi. C. B. P.* Broad-leav'd *German Fleur-de-Lys*, with a ſweet Smell.
28. IRIS *latifolia Germanica, odore ſambuci. C. B. P.* Broad-leav'd *German Fleur-de-Lys*, ſmelling like Elder.
29. IRIS *latifolia Germanica ochroleucos. C. B. P.* Broad-leav'd *German Fleur-de-Lys*, with a yellowiſh white Flower.
30. IRIS *latifolia Germanica candido-purpurea. C. B. P.* Broad-leav'd whitiſh purple *German Fleur-de-Lys.*
31. IRIS *latifolia alba viridis. C. B. P.* White and green broad-leav'd *Fleur-de Lys.*
32. IRIS *latifolia candida, caule aphyllo. C. B. P.* Broad-leav'd white *Fleur-de-Lys*, with a naked Stalk.
33. IRIS *latifolia Belgica, odore ſambuci. C. B. P.* Broad-leav'd *Dutch Fleur-de-Lys*, ſmelling like Elder.
34. IRIS *latifolia Belgica verſicolor, odore ſambuci. C. B. P.* Broad-leav'd *Dutch Fleur-de-Lys*, with a changeable Flower, ſmelling like Elder.
35. IRIS *latifolia Belgica variegata. C. B. P.* Broad-leav'd variegated *Dutch Fleur-de-Lys.*
36. IRIS *Belgica cærulea-verſicolor. C. B. P.* Blue variegated *Dutch Fleur-de-Lys.*
37. IRIS *latifolia humilior purpurea. C. B. P.* Broad-leav'd dwarf purple *Fleur-de-Lys.*
38. IRIS *latifolia humilior verſicolor. C. B. P.* Broad-leav'd dwarf variegated *Fleur-de-Lys.*
39. IRIS *Dalmatica minor. Cluſ. Hiſp.* Small *Fleur-de-Lys* of *Dalmatia.*
40. IRIS *paluſtris lutea. Tabern. Icon.* Yellow marſh *Fleur-de-Lys.*
41. IRIS *paluſtris pallida. Raii Syn.* Pale Water *Fleur-de-Lys.*
42. IRIS *pratenſis anguſtifolia humilior. C. B. P.* Lower narrow-leav'd meadow *Fleur-de-Lys.*
43. IRIS *anguſtifolia candida, lineis rubentibus notata. C. B. P.* White narrow-leav'd *Fleur-de-Lys*, ſtrip'd with reddiſh Lines.
44. IRIS *anguſtifolia, prunum rodolens, minor. C. B. P.* Smaller narrow-leav'd *Fleur-de-Lys*, ſmelling like Plums.
45. IRIS *humilis candicans, venis & orâ cæruleis. Tourn.* Low whitiſh *Fleur-de-Lys*, with blue Veins and Borders.
46. IRIS *humilis Pyrenaica, foliis repandis è luteo vireſcentibus. Tourn.* Low *Pyrenean Fleur-de-Lys*, whoſe bending Leaves are of a greeniſh yellow Colour.
47. IRIS *humilis, foliis repandis vireſcentibus, cum lineis cæ-*

ruleis. Tourn. Low *Fleur-de-Lys*, whoſe bending Leaves are greeniſh, with blue Lines.

48. Iris *humilis flore rubello. Tourn.* Dwarf *Fleur-de-Lys* with a reddiſh Flower.

49. Iris *humilis minor, flore variè picto. Tourn.* Leſſer dwarf *Fleur-de-Lys*, with a variegated Flower.

50. Iris *humilis, flore pallido & albo. Tourn.* Dwarf *Fleur-de-Lys*, with a pale and white Flower.

51. Iris *humilis, flore luteo. Tourn.* Dwarf yellow *Fleur-de-Lys.*

52. Iris *humilis, flore pallidè luteo. Tourn.* Dwarf *Fleur-de-Lys*, with a pale yellow Flower.

53. Iris *humilis candicans, venis variis diſtincta. Tourn.* Dwarf white *Fleur-de-Lys*, ſtriped with various Veins.

54. Iris *humilis ſaxatilis Gallica. Tourn.* Dwarf rock *Fleur-de-lys* of *France.*

55. Iris *humilis latifolia ſaxatilis Luſitanica. Tourn.* Dwarf broad-leav'd rock *Fleur-de-Lys* of *Portugal.*

56. Iris *humilis latifolia major acaulis. Tourn.* Greater broad-leav'd dwarf *Fleur-de-Lys*, without a Stalk.

57. Iris *humilis orientalis, flore dilutè ianthino & veluti leucophæo. Tourn. Cor.* Dwarf Eaſtern *Fleur-de-Lys*, with a pale violet-colour'd, or, as it were, pale whitiſh Flowers.

58. Iris *Americana verſicolor, ſtylo non crenato. Hort. Elth.* Party-colour'd *American Fleur-de-Lys*, whoſe Style is not crenated.

59. Iris *Americana verſicolor, ſtylo crenato. Hort. Elth.* Party-colour'd *American Fleur-de-Lys*, with an indented Style.

60. Iris *Virginiana pumila, ſive Chamæiris verna anguſtifolia, flore purpuro-cœruleo odorato. Baniſt.* Dwarf narrow-leav'd Spring *Fleur-de-Lys* of *Virginia*, with a purple-blue ſweet-ſmelling Flower.

61. Iris *Virginiana pumila, ſive chamæiris verna odoratiſſima latifolia cœrulea repens. Baniſt.* The moſt ſweet-ſcented, dwarf Spring *Fleur-de-Lys* of *Virginia*, with broad Leaves, and a blue Flower.

The firſt ſeventeen Sorts are eaſily propagated by parting their tuberoſe Roots, which commonly increaſe very faſt. The beſt Seaſon for this Work is in *Auguſt*, when their Flower-ſtems are decay'd, and their Leaves begin to change their Colour. But you ſhould obſerve to do it when the Weather is moiſt, otherwiſe the Roots will grow mouldy, and decay: So that if *Auguſt* ſhould prove dry, you may defer doing it 'till *September*; tho' the ſooner it be done, the better, that the Roots may be fixed before the Froſt comes on, which is apt to looſen the Ground, and prevent their taking Root. Theſe Plants ſhould have a ſhady Situation, and a moderately light Soil; but ſhould not be over-dung'd, which is often deſtructive to their Roots: And when they are too much expoſed to the Sun, their Flowers ſoon fall away.

The greateſt Part of theſe Plants grow too large for ſmall Flower-Gardens; and their Leaves generally harbour great Quantities of Snails, and other Vermin, which come forth in the Night, and deſtroy whatever curious Plants grow near them: For which Reaſons they are generally baniſh'd from very curious Gardens, and are proper only for large Gardens, or to plant in Wilderneſs Quarters, where, if the Trees are not too cloſe, they will thrive and flower extremely well, eſecially if the Ground about them be annually dug: And the Flowers being proper Ornaments in Baſons, for Halls, Chimnies, &c. in the Summer Seaſon, they may be allow'd a Place in ſome remote Part of the Garden, where few other Things will thrive.

Theſe Roots ſhould be taken up every other Year, and parted, otherwiſe they will ſpread greatly over the Ground, and become very troubleſome, in harbouring great Quantities of Vermin: or if they are planted in Wilderneſs Quarters, they ſhould be cut round at the leaſt every Year with the Spade, to take off the outſide Roots, and keep them within Compaſs.

The firſt, fourth, and ſeventh Sorts are uſed in Medicine; for which Purpoſe they may be eaſily propagated in the Manner above directed; obſerving to plant the fourth Sort in a warmer Soil than the others; and the ſeventeenth into a moiſt ſhady Situation, where it will thrive exceedingly.

The ſixth, fifteenth, and ſixteenth Sorts are not ſo ſubject to ſpread as the others, and, for their Beauty, may be admitted into every curious Garden: Theſe ſhould be planted under a Wall or Pale where they may have the Morning Sun; but muſt not be expoſed to the great Heat of the Mid-day Sun, which would ſoon deſtroy them: They delight moſt in a freſh, light, loamy, undung'd Soil, and to be pretty moiſt.

Theſe may alſo be propagated by Seeds, which the Plants generally produce in great Plenty; which ſhould be ſaved from ſuch as have variegated Flowers, thoſe being moſt likely to produce the greateſt Variety.

The Seeds ſhould be ſown either in Caſes of Earth, or upon an Eaſt Border, ſoon after they are ripe, which will come up the ſucceeding Spring: But if the Seeds are kept 'till that Time before they are ſown, they will not come up until the ſecond Year, and ſometimes will not grow. The young Plants ſhould be conſtantly kept clean from Weeds, and in dry Weather ſhould be water'd, which will greatly promote their Growth; and the *Michaelmas* following they ſhould be tranſplanted into an Eaſt Border, at about eight or ten Inches Diſtance, where they may continue until they flower, which, in the ſmall Sorts, will be the ſucceeding Spring; but the large Sorts will not flower 'till the third Year from ſowing, when you may mark all ſuch as produce valuable Flowers, which at *Michaelmas* may be tranſplanted into the Garden: But thoſe which are of little Beauty may be pull'd up in flower, and thrown away, to give the better Sorts more Room.

The Sorts from the eighteenth to the thirty-ſixth have been introduced into ſome curious Gardens, from *Germany*, *Spain*, and the *Levant*, which are the Countries of their natural Growth. Theſe are all of them hardy Plants, which will thrive in the open Air in this Climate, and require very little Care to cultivate them; and as they afford a great Variety, and continue long in Flower, (eſpecially in a ſhady Poſition) ſo they merit a Place in every large Garden. Theſe Sorts uſually grow from two to four Feet high in a good Soil; ſo ſhould be placed amongſt hardy Flowers of the ſame Growth.

The thirty-ſeventh, thirty-eighth, and thirty-ninth Sorts, are of lower Growth than either of the former; theſe ſeldom riſe above a Foot high, but have Leaves as broad as thoſe before-mentioned, but they do not ſpread ſo faſt by their Roots, ſo do not require ſo much Room. Theſe Sorts flower earlier in the Spring, than the tall growing Kinds; therefore, if ſome of theſe Roots are planted in a warm Poſition, their Flowers will appear in *March*; and thoſe which have an Eaſt Expoſure, will ſucceed theſe; ſo that ſome of them may be continued near two Months in Beauty.

The fortieth and forty-firſt Sorts grow wild in marſhy Places in ſeveral Parts of *England*; but the forty-firſt is much leſs common than the fortieth, which is found in ſtanding Waters and Ditches almoſt every-where. The Roots of this Sort are uſed in Medicine, under the Title of *Acorus adulterinus*, or *falſe Acorus.* Theſe two Sorts being very common, are ſeldom allowed a Place in Gardens; but where there happens a Bog, or any low moiſt Place in a Garden, ſome of theſe Plants may be planted there to make a Variety.

The forty-ſecond Sort grows wild in moiſt Meadows in *France* and *Germany*; but is not a Native of this Country. This Sort hath narrow Leaves, and is a much leſs Plant than either of the former; ſo may be allowed a Place in ſhady moiſt Borders for the ſake of Variety, being a very hardy Plant, and requiring very little Care to cultivate it.

The forty-third, forty-fourth, forty-fifth, forty-ſixth, forty-ſeventh, forty-eighth, forty-ninth, fiftieth, fifty-firſt, fifty-ſecond, fifty-third, fifty-fourth, fifty-fifth, fifty-ſixth, and fifty-ſeventh Sorts, are alſo of humble Growth, ſeldom riſing above eighteen Inches high; theſe have alſo narrow Leaves, and do not ſpread ſo much as thoſe Sorts before-mentioned; ſo may be allowed Places in ſmaller Gardens, becauſe there is a great Variety in their Flowers. They ſhould be planted in an Eaſt Border, where the Soil is rather moiſt than dry; in which Poſition they will thrive, and produce a great Number of Flowers. The Places of their natural Growth are mentioned to their different Names; from whence their Seeds or Roots may be procured.

The fifty-eighth, fifty-ninth, ſixtieth, and ſixty-firſt Sorts, are Natives of *America*, from whence their Seeds and Roots have been ſent into *England*: The fifty-eighth and fifty-ninth Sorts were ſent from *Maryland*, where their Roots are uſed in Venereal Caſes. Theſe flower late in the Summer, after all the other Sorts are paſs'd, ſo ſhould be admitted into every curious Garden; for they are as hardy, and require as little Care to cultivate them, as any of the before-mentioned Kinds.

All theſe Sorts of Flower-de-luce may be propagated by parting of their Roots; the beſt Seaſon for performing this is at *Michaelmas*, that they may be well rooted before the Froſt begins; for if it be delayed till Spring, the Plants will require to be frequently watered, if the Seaſon ſhould prove dry; and they will not flower near ſo ſtrong, as thoſe which were well rooted before Winter. The dwarf and narrow-leav'd Kinds may be removed and parted every ſecond or third Year; becauſe as theſe do not ſpread ſo faſt as the larger Kinds, ſo they may be eaſily kept within Compaſs, without being tranſplanted often. But all the larger Sorts ſhould be either removed and parted every Year, or dug about and reduced; otherwiſe they will ſpread ſo much as to injure ſuch Plants as grow near them: Indeed, in ſuch Places where they are planted under Trees in large Wood-work, where they are allowed Room enough, they may be permitted to grow many Years unremoved.

Theſe large growing Sorts will thrive very well under Trees in Wilderneſs Quarters (provided the Shade be not too great); in which Places they will continue a long Time in Flower, and make a pretty Variety.

All the Sorts of Flower-de-luce may be propagated by Seeds, as before-mention'd.

IRIS BULBOSA. } *Vide* Xiphium.
IRIS PERSICA. }

ISATIS; Woad.

The *Characters* are;

The Flower conſiſts of four Leaves, which are diſpoſed in form of a Croſs; out of whoſe Flower-cup riſes the Pointal, which afterwards turns to a Fruit in the Shape of a Tongue, flat at the Edge, gaping two Ways, having but one Cell, in which is contain'd, for the moſt part, one oblong Seed.

The *Species* are;

1. Isatis *ſativa, ſive latifolia. C. B.* Broad-leaf'd manured Woad.
2. Isatis *ſylveſtris, vel anguſtifolia. C. B.* Narrow-leaf'd wild Woad.
3. Isatis *Dalmatica major. Bobart.* Greater *Dalmatian* Woad.

There are ſeveral other Varieties of this Plant, which are preſerv'd in ſome curious botanick Gardens: But as they are Plants of little Uſe or Beauty, ſo I ſhall omit mentioning them here.

The firſt Sort is that which is cultivated, in *England*, for the Uſe of *Dyers*, who uſe it for laying the Foundation of many Colours, eſpecially all Sad-colours.

It is a very rich Commodity, and well worth the propagating, which is done by Seed.

The Soil that it requires, is one that is dry and warm: It will not be amiſs if it be a little gravelly or ſandy; and it ſhould have reſted long, to be in good Heart: And the richeſt Garden Ground near great Towns is the beſt, tho' it will do well in many other Places.

Woad is commonly ſown upon a Lay, which they plough into high Ridges, except the Land be very dry, and they harrow the Turf 'till they break it to Pieces, and pick out all the Graſs, Weeds, and Lumps of Earth, and fling them into the Furrows to rot.

The Land for this Seed ought to be finely plough'd and harrow'd, and all the Clods and Turfs broke, and the Stones pick'd up and carry'd off.

The beſt Time for ſowing it, is the latter End of *July*, ſoon after the Seed is ripe, which will come up in *Auguſt*, and muſt be hough'd out, as is practis'd to *Turnips*, leaving the Plants ten or twelve Inches aſunder; by which means they will grow ſtrong, and produce much larger Leaves: And beſides, that ſown at this Seaſon doth ſeldom miſcarry; whereas, that which is ſown in the Spring will be very liable thereto; and if it doth not, the Plant will not have half the Strength the firſt Summer.

It ought to be kept conſtantly weeded; but if it come up good, it will need the leſs weeding: The ordinary Price of Weeding is Eight Shillings *per* Acre.

Some recommend the ſowing of it about the Beginning of *February*; for which they give this Reaſon, That whereas it is apt to be ſpoil'd by the Fly and Grub, it eſcapes the better being early ſown; and if they do kill any of it, they have the better Opportunity of ſowing more.

They do this by making Holes with a Stick about ſeven or eight Inches aſunder, and put five or ſix Seeds into each Hole.

They ſeldom or never ſow it more than two Years upon the ſame Piece of Land; becauſe if it be long continued, it robs the Soil: But if it be moderately uſed, it prepares Land for Corn; and where the Soil is rank, it abates the too great Fertility of it.

It is ripe when the Leaf is come to its full Growth, and retains its perfect Colour, and lively Greenneſs, which is ſometimes ſooner, and ſometimes later, as the Year proves dry or moiſt.

As ſoon as it is fit to cut, it ſhould be done with all the Speed that poſſibly may be, that it may not fade, or grow pale; and when it is cut, it ought to be immediately carry'd to the Mill. The Manner of doing which, and the Way of ordering it, is beſt learn'd from experienced Workmen, and is not to be truſted to a verbal Deſcription of it.

In ploughing it up, and ſowing it again, they pick up all the old Roots as they harrow it, except what they deſign for Seed, which they let ſtand to the next Year: It many Times produces fifty Quarters upon an Acre.

They always keep a good Quantity of Seed by them, to plant the Ground that fails: The Seed of two Years old will ſometimes grow as well as at the firſt. And if they ſow or plant it late, if the Ground be dry and hard, they ſteep it in Water the Day before they ſow it, which cauſes it to come up the ſooner.

Good *Woad* may yield five or ſix Crops in a plentiful Year; tho' it ordinarily yields but four, ſometimes but three, eſpecially if it be let ſtand to grow for Seed: But what grows in Winter they do not uſe, tho' it is very good for Sheep. The two firſt Crops are the beſt, which are uſually mixed in the ſeaſoning. The latter Crops are much the worſe, which, if mixed with either of the former Crops, ſpoil the whole.

It many Times ſells from ſix Pounds to thirty Pounds a Ton, an Acre commonly yielding about a Ton.

ISORA, The Screw-tree.

The *Characters* are;

It hath a ſpreading anomalous Flower, conſiſting of one or many Leaves, divided into ſeveral Parts, and appearing like two Lips: from the Bottom of the Flower ariſes the Pointal, whoſe Apex afterward becomes a twiſted Fruit, conſiſting of many Cells, which are intorted like a Screw; in which are contained ſeveral almoſt kidney-ſhaped Seeds.

The *Species* are;

1. Isora *althææ foliis, fructu breviori & craſſiori. Plum. Nov. Gen.* The Screw-tree with marſh-mallow Leaves, and a ſhorter and thicker Fruit.
2. Isora *althææ foliis, fructu longiori & anguſtiori. Plum. Nov. Gen.* The Screw-tree with marſh-mallow Leaves, and a longer and ſlenderer Fruit.
3. Isora *althææ folio ampliſſimo, fructu craſſiſſimo & villoſo. Houſt.* The Screw-tree with very large marſh-mallow Leaves, and a very thick hairy Fruit.

Theſe Plants are Natives of the *Eaſt* and *Weſt-Indies*, where they grow to the Height of ten or twelve Feet, and become ſhrubby. The firſt of theſe Sorts I received from the *Bahama Iſlands*, where it grows in great Plenty; as alſo in ſeveral other Places in the warm Parts of *America*. The ſecond Sort was found by Mr. *Robert Millar*, Surgeon, at *Carthagena* in the *Spaniſh Weſt-Indies*, from whence he ſent the Seeds to *England*; from which there have been ſeveral Plants raiſed. The third Sort was diſcovered by Dr. *William Houſtoun* in *Jamaica*; who ſent the Seeds and dried Samples of this Kind to *England*.

All theſe Plants are propagated by Seeds, which ſhould be ſown in Pots, filled with light rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark, being careful to water the Earth as often as it appears dry; and if the Nights prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats, to preſerve a gentle Warmth in the Bed; but in the Heat of the Day, the Glaſſes ſhould be raiſed to let the Steam of the Bed paſs off, as alſo to admit freſh Air. When the Plants begin to appear, they ſhould be gently refreſhed with Water three or four times a Week, and the Weeds muſt be carefully pulled up out of the Pots; otherwiſe they will ſoon ſpread over the young Plants, and deſtroy them. The Glaſſes of the Hot-bed muſt alſo be tilted every Day when the Weather is warm, to admit freſh Air to the Plants, to prevent their being drawn up too weak; and when they are grown about three Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to ſhade them until they have taken new Root; after which time the Glaſſes of the Hot-bed ſhould be raiſed every Day, in proportion to the Warmth of the Seaſon, to admit freſh Air to the Plants; and they muſt be frequently watered in hot Weather, for they are thirſty Plants. During the Summer Seaſon theſe Plants may remain in the Hot-bed (provided they are not ſo high as to touch the Glaſſes); but at *Michaelmas* they ſhould be removed into the Stove, and plunged into the Bark-bed. During the Winter they ſhould be kept very warm, and they muſt be often watered; and if their Leaves contract Filth, they ſhould be waſhed with a Sponge; otherwiſe Inſects will attack them, which will weaken and deſtroy the Plants.

Theſe Plants are too tender to thrive in the open Air in this Climate, if they are expoſed thereto, even in the warmeſt

Seaſon; ſo that they ſhould conſtantly remain in the Stove, obſerving in very hot Weather to open the Glaſſes of the Stove, to admit freſh Air to the Plants, and to give them plenty of Water; as alſo to ſhift them into larger Pots, as they increaſe in Magnitude. With this Management the Plants will thrive very well, and in two Years, from Seed, will produce their Flowers and Fruits.

The Name *Iſora*, which Father *Plumier* has given to this *Genus*, is the *Indian* Name for the Plant; but by the *Engliſh* Inhabitants of *America*, it is called *Screw-tree*, from the Form of the Fruit, which is twiſted like a Screw.

JULY FLOWER. *Vide* Caryophyllus.

JULY.

Work to be done in the KITCHEN GARDEN

The Beginning of this Month ſow the laſt Crop of Kidney Beans, where they may be defended from Morning Froſts in Autumn; for this Crop will continue bearing 'till *Michaelmas*, provided they are not injured by Froſt. If the Ground is very dry when theſe are planted, it will be proper to ſoak the Beans ſix or eight Hours in Water before they are planted, which will greatly facilitate their Growth.

Clean the Ground where your Summer Cauliflowers grew, from their Leaves, and any other Rubbiſh which may be there; and if you have Cucumbers for Picklers, between the wide Rows (as is the common Practice of the *London* Gardeners) you muſt draw up the Earth round the Holes with a Hough, forming it in a Hollow like a Baſon, to contain the Water given them; and if there are Cabbages for Winter Uſe in the narrow Rows (which is alſo practiſed) they ſhould have Earth drawn to their Stems, and the whole Ground intirely clear'd from Weeds.

About the Middle of this Month you ſhould ſow Spinach for Winter Uſe, as alſo Coleworts, Carrots, and Onions to ſtand the Winter for Spring Uſe; and Turneps ſhould now be ſown in the open Field for Winter Uſe. Tranſplant Savoys, Broccoli, and Cabbages for Spring Uſe, and plant out Cauliflowers for the Autumn Crop.

Plant Celery into Drills for blanching, (if it be of the *Italian* Sort; but if it be the Turnep rooted Sort, it is better to plant it on level Ground) and plant out Endive for blanching. Continue ſowing all Sorts of ſmall Sallad-herbs, which at this Seaſon do ſoon grow too large for Uſe.

In dry Weather obſerve to water all ſuch Plants as have been lately tranſplanted, and be ſure always to do this in an Evening; for one Watering at that Time is of more Service than three at any other Time of the Day, the Moiſture having Time to penetrate the Ground (and reach to the extreme Fibres of the Root, by which they receive their Nouriſhment) before the Sun appears to exhale it; whereas when it is given in a Morning, the Sun coming on ſoon after, the Moiſture is drawn up before it reaches the Root.

You muſt now diligently deſtroy the Weeds in every Part of the Garden, which, if ſuffered to remain, will ſoon perfect their Seeds; and when theſe are permitted to ſcatter upon the Ground, they will fill it with Seeds for a ſeven Years Crop, to the no ſmall Trouble of the Gardener, as alſo to the great Injury of the Crops. Obſerve alſo to clear your Dunghils from Weeds, for theſe are too often neglected; and if the Weeds are permitted to feed there, they will be brought into the Garden, and be as troubleſome as if they had ſcattered in the Garden; which is what few People regard, tho' it is a Thing of great Moment, as is alſo the keeping the Borders round the Outſide of the Garden free from Weeds, eſpecially thoſe which have downy Seeds; for theſe will be wafted by the Winds into the Garden, and produce a plentiful Crop.

Gather Seeds of all Sorts that are ripe, cutting off their Stalks, and ſpread them upon Mats or Cloths in a dry airy Place that they may harden, and then rub or beat them out of their Huſks or Pods, and put them up in a Place where Vermin can't come to them to deſtroy them.

Pull up Onions, Garlick, Rocamboles, Shallots, *&c.* when their Leaves begin to wither, and ſpread them thin in a dry airy Place, that they may be perfectly dry before they are laid up for Winter Uſe.

Continue to earth up Celery which was planted in the Drills the former Month, as it advances in Height: but be careful not to draw the Earth up into the Heart or Middle of the Plants; for that will ſtop their Growth, and rot them: And tie up the Endive, which is full grown, to blanch it, obſerving always to do this Work in dry Weather; for if the Leaves are moiſt when they are ty'd, they will rot.

Pull up the Stalks of Beans, Cabbages, *&c.* and the Haulm of Peaſe, and other leguminous Plants which have done bearing, that the Ground may be clear; for if theſe are permitted to remain, they will harbour Vermin, to the Prejudice of your other adjoining Crops.

Your Melons which now begin to ripen, ſhould have very little Water given them, becauſe it would render them watery and ill-taſted; tho' ſuch Perſons who are fond of very large Fruit, do find their Account in ſupplying their Plants conſtantly with Water in great Plenty, eſpecially in hot Weather: but theſe Perſons do not regard the Quality of their Fruit, ſo much as the Size of them.

In this Month you may repair your young Aſparagus-beds which were planted the laſt Spring, by planting freſh Plants where any of them have failed: but this ſhould be done in moiſt Weather.

The Cucumbers which were brought up under Hand-glaſſes, being now in full Bearing, muſt be duly watered in dry Weather, otherwiſe they will be exhauſted in a ſhort Time, and decay.

Clear the Artichokes which were planted the laſt Spring from Weeds, and all other Crops, that they may have full Liberty to ſpread; for if they are crouded with any other Plants at this Seaſon, they will produce ſmall Fruit: And thoſe Artichokes which are now cut for Uſe, ſhould have their Stems broken down cloſe to the Root, that the Stocks may not be injured thereby.

Products of the KITCHEN GARDEN.

Cauliflowers, Artichokes, Cabbages, Carrots, Beans, Peaſe, Kidney-beans, Turneps, Lettuce, Cucumbers, Melons, and all Sorts of ſmall Sallad, as Radiſh, Rape, Muſtard, Creſſes, Purſlain, and in ſome Places Celery and Endive, Finnochia, Onions, Garlick, Rocambole, and moſt Sorts of Herbs for diſtilling.

Work to be done in the FRUIT GARDEN *and* VINEYARD.

The Beginning of this Month you muſt look carefully over your Wall and Eſpalier-trees, rubbing off all foreright Shoots that are produced, and train in all ſuch regular Shoots as are deſign'd to remain cloſe to the Wall or Eſpalier in their due Poſition, whereby the Fruit will have the Advantage of Sun and Air to ripen them, and give them their proper Flavour. If this be rightly executed, there will be no occaſion to diveſt the Branches of their Leaves, (as is by ſome unſkilful Perſons practiſed, to the great Prejudice both of their Fruit and Trees): Nor can I here forbear repeating what I have elſewhere often taken notice of, *viz.* not to ſuffer Fruit-trees to remain neglected till this Seaſon, (as is too commonly practiſed) and then to Summer-prune them, as it is called, when they cut off all the luxuriant Branches, and ſhorten thoſe deſigned to remain, and then nail them cloſe to the Wall; ſo that from being (before this Dreſſing) in a very rude diſorderly Way, they are reduced into an exact Order at once: but hereby the Fruit, which was greatly ſhaded by the luxuriant Growth of the Branches, is ſuddenly expoſed to the Sun and Air, which hardens their outward Skins, and retards their Growth; whereas if the Shoots had been conſtantly train'd to the Wall or Eſpalier, the Fruit would have continually been under an equal Coverture of Leaves, and ſo conſequently leſs liable to ſuffer from any Extremes; and will alſo be conſiderably earlier, than when they are managed in the other way: ſo that as this Practice is too generally follow'd, I think it cannot be too much expoſed, and the proper Directions cannot be too often inculcated.

In the Beginning of this Month you muſt bud all Sorts of Fruits, which were not done the preceding Month, obſerving always to do it in an Evening, or in cloudy Weather.

Hough and clean your Nurſeries of young Trees from Weeds, as alſo the Borders near your Fruit-trees; for if they are permitted to grow at this Seaſon, they will rob the Trees of their Nouriſhment: and cut off all Suckers which ariſe from the Roots of the Trees, as they are produced; for theſe injure them much, if they are ſuffer'd to remain.

Look carefully after Snails in the Morning and Evenings, but eſpecially after a Shower of Rain, when they will be tempted to come abroad, and may be at that Time eaſily taken; for theſe Vermin do great Miſchief to Stone-fruit.

Place Glaſs Phials fill'd with Honey-water in different Parts of your Walls, to deſtroy the Waſps and Piſmires, which would infeſt your choice Fruit, but are, by the Sweetneſs of the Water tempted into the Phials, and frequently drowned.

The Vineyard muſt now be carefully look'd over, and all dangling Shoots and wild Wood muſt be diſplaced, that the Fruit may not be too much covered with Leaves; but by no means diveſt any of the Fruit-branches of their Leaves, (as ſome unſkilful Perſons too often practiſe) for theſe are abſolutely neceſſary to the Growth of the Fruit: Nor will there be any Occaſion for this Practice where the Shoots are duly placed, and the wild Wood conſtantly rubb'd off as it is produced. Where this Method is begun early in the Seaſon, and conſtantly purſu'd as there may be Occaſion, the Fruit will be forwarded above three Weeks, (as I have experienced) and will be much fairer, and better-taſted, than in the contrary Management; for when the Shoots of the Vines are permitted to hang looſe from the Walls or Stakes, their Leaves will take a contrary Direction; which, upon having their Shoots afterwards ty'd up, will have their Back-ſide upwards; and until their Leaves are turn'd into their proper Poſition, the Fruit will be at a Stand, and make no Progreſs in their Growth, which is commonly eight or ten Days in effecting; ſo that the Fruit loſes eight or ten Days in the principal Seaſon of its Growth, which, together with being too much ſhaded in the former Month, is ſcarcely ever to be retrieved in this Climate.

You muſt alſo keep the Ground conſtantly clear'd from Weeds and other Plants between the Rows of Vines, which is alſo of great Conſequence in this Country; for where there are other Plants ſuffered to grow, they not only rob the Roots of the Vines of their Nouriſhment, but alſo, by perſpiring, do cauſe a Damp in the Air about the Vines, and prevent the Sun and Wind from drying the Surface of the Ground, whereby the Fruit is fill'd with crude Nouriſhment, and render'd leſs delicate.

Fruits in prime, or yet laſting.

Pears; The Primitive, Robine, Petit Muſcat, Muſcadelle-rouges, Cuiſſe Madame, Petit Banquette, Jargonelle, Green Chiſſel, Orange Muſque, Windſor, Calliorosat, with ſome others; and where they have been well preſerved, the Black Pear of Worceſter, and Lord Cheney's Green Pear, are yet in being.

Apples; Codling, Margaret Apple, White Juneating, Stubbard's Apple, Summer Coſting, Summer Pearmain, Pomme de Rambour; and ſtill continue the Deux-ann's or John-Apple, the Stone-Apple, and Oaken Pin.

Cherries; Kentiſh, Gaſcoign's Heart, Carnation, Lukeward, Ox-Heart, Amber-Heart, Coroon, Amber, White Spaniſh, and Black Cherries.

Peaches; Brown and White Nutmeg, Anne Peach, Albemarle, Smith's Newington, Bellis or Bellows, Red Magdalen, Roſſanna, Minion, Montabonne, Bordine, Royal George, Early Admirable, and ſome others.

Nectarines; Fairchild's Early Nutmeg, Roman Red, Elruge, Brunion, and Newington.

Plums; Jean Hative, Morocco, Orleans, Blue Primordian, Violet Royal, Blue Perdrigon, Mirabelle, Imperial, White Matchleſs, Maitre Claude, Green Gage, Damoiſine, Drap d'Or, Gros Damas Violet, Cheſton, with ſome others of leſs Note.

Apricots; The Orange, Roman, Breda, Algier, Bruxelles, and Turkey.

As alſo Gooſeberries, Raſpberries, Currants; and in the Stove, the Ananas or Pine-Apple.

Work to be done in the NURSERY.

Continue to bud Apricots, Peaches, Nectarines, Cherries, Plums, Pears, *&c.* This Method ſhould, if poſſible, be done in a cloudy Day, or in a Morning or Evening, when the Sun is not violent; becauſe the Cuttings are very apt to ſhrink in very hot Sunſhine, which cauſes the Buds to adhere too cloſely to the Wood, unleſs they are put in Water, which is what moſt People practice: but this is not ſo proper; for thoſe Buds which are cover'd with Water will be ſo much ſaturated with Moiſture, as to prevent their attracting from the Stock, ſo that they often miſcarry.

In about three Weeks after the Stocks are budded, you ſhould look over them to looſen the Bandage, otherwiſe the Buds will be pinched, and deſtroyed.

Obſerve to keep your Nurſery clean from Weeds at this Seaſon; for now the Weeds will ſoon ripen their Seeds if they are permitted to remain, which will fill the Ground ſo as not to be cleared again for Years.

You muſt continue to train your Ever-green Trees for the Purpoſes they are deſigned; and where any of your Foreſt Trees ſhoot too vigorouſly near their Roots, thoſe Branches may be pruned off to encourage their Heads.

Keep your Beds wherein your young Stocks and Trees were ſown in the Spring, clear from Weeds; and in very dry Weather ſupply them with Water, which will greatly promote their Growth.

Work to be done in the PLEASURE GARDEN *and* WILDERNESS.

Take up the Bulbs of ſuch late Flowers as were not fit the laſt Month; ſuch as Ornithogalums, White Lilies, Martagons, and ſome other Sorts; and tranſplant the Roots of Perſian and Bulboſe Iris's, as alſo Fritillaria's, Hyacinth of Peru, Dens Canis, Narciſſus's, and ſuch other Bulboſe-rooted Flowers which will not endure to be kept long above Ground; and this being the Time they are not in Action, is the moſt proper Time for tranſplanting them, before they put forth new Fibres, after which Time it will not be proper to remove them.

Continue to make Layers of Pinks, Carnations, Sweet-Williams, *&c.* (where it was not done the former Month): but the ſooner this is done the better, provided the Shoots are ſtrong enough to lay down.

Tranſplant ſuch Biennial or Perennial Fibroſe-rooted Flowers as were ſown late in the Spring; ſuch as Pinks, Carnations, Stock-gilliflowers, Wall-flowers, Hollyhocks, French Honeyſuckles, Canterbury Bells, and ſome others, which ſhould be planted in Nurſery-beds, where they may have Room to grow till *Michaelmas*, when they ſhould be tranſplanted into the Borders of the Flower-Garden.

Clean your Borders diligently from Weeds, but eſpecially ſuch Sorts as ſoon ſhed their Seeds; for if they are permitted to ſtand until their Seeds are ſcatter'd, it will be a conſtant Trouble, for ſeveral Years, to extirpate them.

Gather the Seeds of all Sorts of Flowers as they ripen, and preſerve them in their Huſks or Pods until the Seaſon for ſowing them: but you ſhould dry them carefully before they are put up, otherwiſe they will grow mouldy, and decay.

Cut down the Stalks of ſuch Flowers as begin to wither and decay, and tie up all tall growing Plants which are yet to flower, leſt the Winds blow them down, and break them.

Inoculate Roſes, Jaſmines, and other Sorts of curious flowering Shrubs and Trees; this Month being the principal Seaſon for that Work.

Cut and trim Hedges, clip Box-edgings, mow Graſs-plots, and keep the Walks conſtantly rolled, and the Weeds ſhould be taken out of them; for if they are ſuffered to remain at this Seaſon, they will ſeed in a little Time, and fill the Walks with Weeds.

Your choice Carnations being now in flower, ſhould be carefully attended, to open the Pods when they begin to burſt on the contrary Side, that they may blow equally; for if this be not done in time, the Leaves will come all out on one Side of the Pod, and render them ill-ſhaped. You muſt alſo guard them from Inſects, which will deſtroy them in a ſhort Time, if they can come to them; and they ſhould be covered with Glaſſes or Baſons to keep off the Wet, and the ſcorching Heat of the Sun. But in all this there muſt be great Diligence in managing them according to the Temperature of the Seaſon, where Perſons would excel in the Largeneſs and Beauty of their Flowers; therefore theſe are not ſo proper for Perſons who have other Buſineſs on their Hands, but rather for thoſe who want ſome ſuch eaſy Employment to divert themſelves.

You may now increaſe the Double Scarlet Lychnis, by planting Cuttings of it in a ſhady Border of light freſh Earth, obſerving to refreſh them with Water according to the Drought of the Seaſon.

Toward the latter End of this Month you may take off the Layers of Pinks, Carnations, Sweet-Williams, *&c.* which have taken Root, and plant them either into Pots or Borders of good freſh Earth, where they may continue until you have Conveniency of planting them where they are to remain for flowering; for it is not proper to let them continue too long upon the old Roots; becauſe, if they ſhould not be ſound, the Layers would be infected by them: but when you plant theſe out, they muſt be carefully watered and ſhaded until they have taken Root.

The latter End of this Month you ſhould ſow ſome Seeds of Annual Flowers, in warm Borders, to ſtand the Winter, that they may flower early the next Summer; by which Method you may obtain good Seeds of many Sorts of Plants, which, if ſown in the Spring, do not conſtantly produce good Seeds; ſuch as the Great Blue and Fleſh-colour'd Lupines, Sweet-ſcented Pea, Sweet Sultan, Indian Scabious, Double Larkſpur, Dwarf Annual Stock, Venus Navelwort, Xeranthemums, Jacea's, with ſome others. Theſe Plants will not only come earlier to flower, but alſo will grow much larger, and produce their Flowers in much greater Plenty, than if they were ſown in the Spring.

Your choice Auricula's ſhould now be kept clear from Weeds, and all decay'd Leaves; which, if ſuffer'd to remain upon them, would rot and ſpoil them; and they ſhould be plac'd in a ſhady Situaiton, but not under the Droppings of Trees.

The ſeedling Auricula's which came up the laſt Spring, muſt now be planted out into Tubs or Pots fill'd with rich Earth, and placed in a ſhady Situation: and as they are ſmall, ſo they muſt be treated tenderly, giving them Water gently; and be careful that they are not drawn out of the Ground by Worms, nor eaten by Snails or Slugs, both which Vermin are great Enemies to them.

Keep the Walk and Quarters of your Wilderneſs free from Weeds and Litter; and ſuch Trees as grow too much out of Order may be pruned, ſo as to render them beautiful; for this is a Seaſon when Wilderneſſes and ſhady Walks are chiefly frequented; ſo that they ſhould be well kept, otherwiſe they will be diſagreeable.

Plants now in Flower in the PLEASURE GARDEN.

Carnations, Pinks, Sweet-Williams, Fairchild's Mule, Double and Single Ragged Robin, Dwarf Annual Stock, French Willow, Single and Double Virgin's Bower, Antirrhinum or Calf's-ſnout, Linaria's of ſeveral Sorts, Jacea's of ſeveral Sorts, Everlaſting Pea, Sweet-ſcented Pea, Tangier Pea, Blue-flower'd Lathyrus, Hieraciums, White Lily, Scarlet Martagon, Day Lily, Ornitholagum Spicatum, White Hellebore with green Flowers, Aconitum Luteum, Anthora, Acanthus, Lavatera's, Indian Scabious, Sea-Holly, Sweet Sultan, African Poppies of divers Kinds, Peach-leaf'd Campanula, Venus Looking-glaſs, Venus Navelwort, Double Ptarmica, Double Feverfew, Double Camomile, Buphthalmums, Annual Stock Gilliflower, Double Roſe Campion, Larkſpurs, Spaniſh Scorphularia, Nigella, two ſorts of African Marygolds, Lupines of ſeveral ſorts, Amaranthus's, Amaranthoides, Capſicum Indicum, Leucanthemums, Xeranthemums, Red Garden Valerian, Hollyhocks, Lychnidea, Caoliniana, Sunflowers of ſeveral ſorts, Virginian Spiderworts, Scarlet Lychnis, Golden Rod of ſeveral kinds, French Marygold, Female Balſamine, Marvel of Peru, China Pink, ſome ſorts of Starwort, Dwarf Lychnis, Candy Tuft, Mallows of ſeveral kinds, Naſturtium Indicum, Cryſanthemums, Ricinus or Palma Chriſti, Globe-Thiſtle three or four ſorts, Campanula Pyramidalis, Limoniums of ſeveral kinds, Catanance Quorundam, Eupatoriums, Greater Centaury of ſeveral ſorts, Statice Major, Clove Gilliflowers, Double and Single Sopewort, Coronilla Herbacea flore vario, Heliotropium majus, with ſome others.

Hardy Trees and Shrubs now in Flower.

Several ſorts of Roſes, Spaniſh Broom, White Jaſmine, Dwarf Yellow Jaſmine, Canary Hypericum, Shrubby Stinking Hypericum, Double and Single Pomegranate, Virginian Trumpet Flower, Agnus Caſtus or the Chaſte-tree, Maleciſtus ſeveral kinds, Ciſtus Ledon ſeveral ſorts, Phlomis or Sage-tree, Oleaſter, Shrub-Cinquefoil, Spirea with Willow Leaves, Spirea with Marſh-Elder Leaves, Althæa Frutex, Paſſion Flower, Cytiſſus Lunatus, Cateſby's Climber, Bladder Senna, Dutch Honey-ſuckle, Ever-green Honey-ſuckle, Long-blowing Honey-ſuckle, Late White Honey-ſuckle, Scarlet Virginian Honey-ſuckle, the Tulip-tree, Virginian Sumach, Myrtle-leaf'd Sumach, Geniſta, Tinctoria, Geniſtella, Ketmia's, with ſome others.

Work to be done in the GREEN-HOUSE, GARDEN, *and* STOVE.

Gather the Flowers of your Orange-trees, where they are produced too cloſe to each other; and where there was a ſufficient Number of Fruit ſet upon the Trees the former Month, it will be proper to diveſt them of all the Flowers which are now produced; for theſe being too late in the Seaſon, the Fruits which ſucceed them will not have Time to grow to any conſiderable Size before Winter, and ſo will be in Danger of falling off before Spring. You ſhould alſo obſerve, where you may have overlook'd ſome Bloſſoms the laſt Month, which now are become Fruit, to pull them off, leaving but few upon each Tree, and thoſe well ſituated, and upon ſtrong Shoots; for where there are too many Fruits left upon the Trees, it renders them weak; and the Fruit not having Nouriſhment, does ſeldom grow to any conſiderable Size; and where they are upon weak Shoots, they rarely come to any thing.

Continue to make Cuttings of ſuch Exotick Plants which you want to increaſe, provided you have not done it the preceding Month: The beſt Method of planting Cuttings at this Seaſon, is, to prepare a Bed of light rich Earth, into which the Cuttings ſhould be planted, and then arch the Bed over with Hoops, in order to ſhade the Cuttings in hot dry Weather, and obſerve to water them duly, as they may require; but let them be expoſed every Night to receive the Dew, which will be of great Uſe to them: but this is to be practiſed upon ſuch Sorts of Plants as are not very tender, becauſe thoſe will require a moderate Hot-bed to make them root, eſpecially the tender ſucculent Plants, ſuch as Cereus, Euphorbiums, *&c.* but all the Sorts of Geraniums, Myrtles, Jacobeas, and other Shrubs from the *Cape of Good Hope*, will take root much better in a Bed of rich Earth, than if planted in a Hot-bed.

Shift ſuch Exotick Plants as have been rais'd from Seeds in the Spring, putting them into larger Pots according to their various Growth, and plunge ſuch of them as are tender into the Hot-bed of Tanners-bark, obſerving to water them, and ſhade the Glaſſes, until they have taken new Root; after which they muſt have Air and Water according to the Heat of the Weather.

Waſh and clean the Leaves and tender Shoots of your choice Exotick Plants from Filth and Inſects, both which do commonly infeſt them at this Seaſon, (eſpecially thoſe in the Bark-ſtove); and if they are not clean'd in time, the Plants will ſuffer greatly, and the Inſects will ſpread themſelves over moſt of the other Plants, ſo as not to be eaſily deſtroyed.

In hot Weather you ſhould give your tender Exoticks as much free Air as poſſible, eſpecially when there is not much Wind ſtirring; and in the Middle of the Day it will be proper to ſhade the Glaſſes of the Stove, when the Sun is violently hot, otherwiſe the Earth in the Pots will dry too faſt.

Stir up the Bark of ſuch Beds whoſe Heat begins to decline, and add a little new Bark to them, which will renew the Heat, and cauſe it to continue a conſiderable time longer. At the ſame time, ſuch Plants as require it, ſhould now be ſhifted, giving them larger Pots if their Roots require it.

The Anana's will now ripen very faſt, if the Seaſon is warm; therefore, when the Fruit is cut from the Plants, the Pots with the old Plants ſhould be plung'd into a warm Bed, to force out the Suckers early enough to take off before Winter; in order to which they ſhould be frequently water'd, otherwiſe they will make but indifferent Progreſs.

Make Layers of the Spaniſh, Arabian, and Azorian Jaſmines; as alſo of all the tender Sorts of Granadilla, which will eaſier take Root at the tender Joints of the new Shoots, than from the Shoots of the former Year: but you muſt obſerve to plunge the Pots into which they are laid, in a Hot-bed, otherwiſe they will not ſucceed.

Gather all Sorts of Exotick Seeds as they ripen, and ſpread them upon Papers, in a dry Place to harden and dry; after which they ſhould be carefully preſerv'd in their Pods or Huſks, until the proper Seaſon for ſowing them.

Such of the tender Annuals as will endure the open Air, ſhould now be ſet out of the Hot-beds, in ſome well-ſhelter'd Situation, where they will produce Seeds better than if kept conſtantly in the Beds.

Where any of your tender Stove Plants are very much infeſted by Inſects, or have contracted much Filth upon their Leaves, you ſhould waſh them clean, and expoſe them to the open Air, in a warm Situation, where they may be ſhelter'd from ſtrong Winds, which will be of great Service to the Plants. You ſhould alſo keep ſome of the Top-glaſſes of the Stove conſtantly drawn down, both Day and Night; for at this Seaſon moſt Plants do perſpire freely, which, if pent up too cloſe, will cauſe them to look ſickly, and occaſion their Leaves to change their Colour, ſo that Inſects will ſoon attack them.

Plants in Flower in the GREEN-HOUSE *and* STOVE.

Oranges, Lemons, Limes, Citrons, and Shaddocks, Myrtles of ſeveral ſorts, Amomum Plinii, Barba Jovis or Silver-buſh, Ciſtus halimi folio, Ciſtus Ledon two or three ſorts, Male-Ciſtus of ſeveral ſorts, Spaniſh Jaſmine, Geraniums of ſeveral ſorts, Tree Scabious of two ſorts, Yellow Indian Jaſmine, Azorian Jaſmine, Ilex-leaf'd Jaſmine, and Arabian Jaſmine, Colutea Æthiopica Barbæ Jovis folio, Apocynum Africanum erectum ſalicis folio flore albo, Apocynum Americanum erectum ſalicis folio flore aurantio, Blue and ſcarlet Cardinal's Flowers, Elichryſums of ſeveral ſorts, Caſſia's of two or three ſorts, Acacia Indica Aldini, Guidonia Ulmi facie, ſenſitive and humble Plants of ſeveral ſorts, Coral-tree, Lotus Argentea Cretica, Lotus Hæmorrhoidalis, Anonis two or three ſorts, Granadilla's two or three ſorts, Coffee tree, White Spaniſh Broom, Fabago Africana arboreſcens flore ſulphureo fructu rotundo, Red and White Oleanders, Double Oleander, Sweet-ſcented Oleander, Fritillaria Craſſa, ſeveral ſorts of Ficoides's, Small Creeping Cereus, Large upright Cereus, Ketmia's of ſeveral ſorts, Cotyledons of ſeveral kinds, Ricinus or Palma Chriſti of ſeveral ſorts, Papaya, Ricinoides folio multifido, Ricinoides Goſſipii folio, Ricinoides Staphyſagriæ folio, Cotton-plant, Baſſella, Dracunculoides, Double Indian Naſturtium, Myrto-Ciſtus, Polygala Africana fruteſcens, Digitalis Acanthoides, Heliotropium Scorodoniæ folio, Gnaphaliums, Caltha Africana Croci folio, Viburnums, Phalangiums, Blue African umbellated Hyacinth, Olives, Tetragonocarpos, Rhamnus's, Aloes of ſeveral ſorts, Yucca, Indian flowering Reed, Lilium Zeylanicum, Turnera, Plumeria, Hedyſarums, Lilio-Narciſſus's, Pancratium, with ſome others.

JUNCUS, Ruſh.

The *Characters* are;

It hath a Flower compoſed of many Leaves, which are placed orbicularly, and expand in form of a Roſe; from the Center of which riſes the Pointal, which afterward becomes a Fruit or Huſk, which is generally three-cornered, opening into three Parts, and full of roundiſh Seeds.

The *Species* are;

1. JUNCUS *acutus, capitulis ſorghi. C. B. P.* Prickly large Sea Ruſh.
2. JUNCUS *acutus maritimus Anglicus. Park. Engliſh* Sea-prickly Ruſh.
3. JUNCUS *acutus, paniculâ ſparſâ. C. B. P.* Common hard Ruſh.
4. JUNCUS *lævis, paniculâ ſparſâ, major. C. B. P.* Common ſoft Ruſh.
5. JUNCUS *lævis, paniculâ non ſparſa. C. B. P.* Soft Ruſh, with a more compact Panicle.
6. JUNCUS *acumine reflexo, major. C. B. P.* The greater bending Ruſh.

Theſe Sorts of Ruſhes are not cultivated, but grow wild in ſeveral Parts of *England*; and ſome Sorts of them are very troubleſome Weeds, in low, moiſt ſtrong Lands. The firſt and ſecond Sorts grow on the Sea-ſhores, where they are frequently watered by the Salt-water. Theſe two Sorts are planted with great Care on the Banks of the Sea in *Holland*, in order to prevent the Water from waſhing away the Earth; which being very looſe, would be in Danger of removing every Tide, if it were not for the Roots of theſe Ruſhes; which faſten themſelves very deep in the Ground, and mat themſelves near the Surface, ſo as to hold the Earth cloſely together. Therefore, whenever the Roots of theſe Ruſhes are deſtroyed, the Inhabitants immediately repair them, to prevent farther Damage. In the Summer-time, when the Ruſhes are fully grown, the Inhabitants cut them, and tie them up into Bundles, which are dried, and afterward carried into the larger Towns and Cities, where they are wrought into Baſkets, and ſeveral other uſeful Things, which are frequently ſent into *England*. Theſe Sorts do not grow ſo ſtrong in *England* as they do on the *Maeze*, and ſome other Places in *Holland*, where I have ſeen them upward of four Feet high.

The third and fourth Sorts grow on moiſt ſtrong uncultivated Lands in moſt Parts of *England*, and deſtroy the Herbage where they are ſuffer'd to remain. The beſt Method of deſtroying theſe Ruſhes, is to pare them up clean in *July*; and after having let them lie a Fortnight or three Weeks to dry, to lay them in Heaps, and burn them gently; and the Aſhes which theſe afford, will be good Manure for the Land; but in order to prevent their growing again, and to make the Paſture good, the Land ſhould be drained and well ploughed, and ſown with *Rygraſs*, which will make a good Sward in one Year, if it be rightly managed; for the right ordering of which you are deſired to turn to the Article *Paſture*, where there are proper Inſtructions exhibited.

JUNE.

Work to be done in the KITCHEN GARDEN.

The Beginning of this Month you muſt tranſplant Cabbage and Savoy Plants, which are to ſupply the Kitchen in Winter, either on an open Spot of Ground, or between Rows of Beans, Cauliflowers, *&c.* which will be taken off the Ground in a ſhort Time, and then the new-planted Plants will have Room to grow; and being ſhaded by the other Crops at firſt planting, they will take Root ſooner than if they were planted in an open Situation: And by thus obſerving to put one Crop to ſucceed another, a ſkilful Perſon will produce more Things from one Acre of Land, than ſome others can from two or three, which is what every Perſon, who is acquainted with the *London Gardeners Practice*, muſt be convinc'd of.

The Cauliflower Plants which were ſown the laſt Month for Winter Uſe, ſhould now be prick'd out into Beds of rich Earth, obſerving to ſhade them until they have taken Root, and be ſure to water them duly, otherwiſe they are apt to ſtunt, and be infeſted with Inſects.

Hough and clean Carrots, Parſnips, Turnips, Onions, Leeks, Beets, and all other late Crops; for if the Weeds are permitted to grow at this Seaſon, many of them will ſhed their Seeds in a ſhort Time, and become troubleſome hereafter, and the larger Sorts will over-bear the Crops, and draw them to their great Prejudice.

You may yet make Slips of Sage, Roſemary, Stœchas, Lavender, Hyſſop, Winter Savory, and other Aromatick-plants; tho' it had been better if done earlier in the Year, becauſe this Month often proves hot and dry, and the Plants having long tender Shoots, are in greater Danger of miſcarrying.

Plant out young Plants of all Sorts of ſweet Herbs which were ſown in *March*, as Thyme, Hyſſop, Sweet-Marjoram, *&c.* and alſo Clary, Burnet, Sorrel, Marygolds, and many other Sorts, obſerving to allow them Room enough to ſpread, which will render them much ſtronger than thoſe which remain in the Seed-beds.

Clear and hough the Ground whereon your earlieſt Cauliflowers grew, which will be all gone by the middle or latter end of this Month. And if you have Ridges of Cucumbers or Melons made between the Rows of Cauliflowers, (as is the Practice of the *London Gardeners*) you ſhould dig all the Ground between the Ridges, and lay out the Vines in regular Order; this will not only looſen the Ground for the Roots of the Plants but alſo deſtroy the Weeds, and render the Surface of the Ground wholſomer for the Vines to lie upon: But in doing of this you ſhould be very careful not to bruiſe or break the Vines, which would be very injurious to them, and (if poſſible) let it not be done in moiſt Weather.

Sow Turnips upon a moiſt Spot of Ground, and when there is a Proſpect of Rain in a little Time, which will bring up the Plants in a few Days; for in dry Weather the Seeds will remain in the Ground, and not vegetate; beſides, if the Plants do come up, and the Weather be very hot and dry, the Fly will take them, and deſtroy them in a ſhort Time.

In the Beginning of this Month you may ſow ſome Brocoli-ſeed for the ſecond Crop, and Finnochia, to ſucceed that which was ſown in the Middle of the former Month; for in very hot weather this Plant will not remain good above a Fortnight, before it will run to Seed; ſo that if it be not often ſown, there will be a Want to ſupply the Kitchen.

Tranſplant Celery into ſhallow Trenches for blanching, allowing about four or five Inches Space between each Plant in the Rows, and make the Trenches three Feet aſunder, that there may be Room enough to earth up the Plants when they are full grown.

Plant Kidney-Beans to ſucceed thoſe which were planted in *April*; and ſow Brown Dutch, and Common Cabbage-Lettuces, for a late Crop; and tranſplant ſuch Lettuces as were ſown in *May*, obſerving to place them in a ſhady Situation, but not under Trees, nor near Walls or other Buildings, which will draw them up weak, and prevent their cabbaging.

Tranſplant Endive in an open moiſt Spot of Ground for blanching, allowing the Plants a Foot Diſtance each Way, that they may have Room to ſpread, and ſow ſome Endive-ſeed for a latter Crop.

Continue to ſow ſmall Sallet herbs every three or four Days, ſuch as Creſſes, Muſtard, Turnip, Rape, Radiſh, *&c.* for at this Seaſon they will ſoon grow too large for Uſe.

You muſt now thin the Finnochia-plants which were ſown the former Month, obſerving to allow them Room enough to grow, otherwiſe they will draw up weak, and never ſwell at Bottom; but the Plants which are taken out ſhould not be tranſplanted, for they rarely are good for any Thing, being very ſubject to run to Seed, before they arrive to any Size.

The Broccoli which was ſown in *May* ſhould be now prick'd out into Beds at about three Inches aſunder, where they will grow ſtrong, in order for planting out the next Month; for where they are ſuffer'd to grow in the Seed-bed too long, they draw up weak, and never produce ſo good Heads, as thoſe which are ſhort and ſtrong in their Stems.

Weed and thin the Plants in your Cucumber-holes which were ſown for pickling, obſerving to leave but four of the ſtrongeſt and beſt ſituated Plants in each Hole, and at the ſame Time earth up their Shanks, which will greatly ſtrengthen them, and give them ſome Water to ſettle the Earth about them.

In dry Weather gather Seeds of all Sorts that are ripe, ſpreading them upon Mats or Cloths to dry, before they are rubb'd or beaten out of their Huſks or Pods.

Gather Herbs for drying of ſuch Sorts as are now in Flower, and hang them up in a dry ſhady Place, where they may dry leiſurely, which will render them better for any Purpoſe, than if they were dried in the Sun.

Your Melons which are now Setting, ſhould be ſhaded in the Heat of the Day with Mats, if the Weather be warm, otherwiſe their Fruit will drop; and you ſhould be careful not to give them too much Water, which is often injurious to them.

Gather up Snails in the Morning and Evening, and after Showers of Rain, at which Times they will come abroad from their Holes and Places of Harbour, ſo that they are eaſily deſtroy'd.

The Weeds which now come up in moſt Gardens, are Wild Orachs, Nightſhade, Thorn-Apple, Groundſel, ſow-Thiſtles, *&c.* which if permitted to grow amongſt Crops, will ſoon out-grow them, and ſpoil whatever Plants are near them.

You may now tranſplant Leeks out of the Seed-beds in the Places where they are to remain, obſerving to water them until they have taken Root: This is often practis'd in ſmall Gardens, where an early Crop of Beans or Cauliflowers have been produc'd on the ſame Ground, before the Leeks are put on it.

Products of the KITCHEN-GARDEN.

Cauliflowers in Plenty, Cabbages, young Carrots, Beans, Peaſe, Artichokes, Aſparagus, Turnips, Cucumbers, Melons, Kidney-Beans, Cabbage-Lettuces of various Kinds; all Sorts of young Sallet-herbs, as Chervil, Creſſes, Muſtard, Rape, Radiſh, Corn-ſallet, *&c.* ſome Early Finnochia, with other Kinds.

All ſorts of Sweet-herbs, as Lavender, Thyme, Winter Savory, Hyſſop, Marum, Maſtick, Stœchas, *&c.* as alſo Sage, Roſemary, Origanum, Mint, Baum, Penny-Royal, Parſley, Sorrel, Burnet, Bugloſs, Borage, with many other Kinds of Medicinal or Culinary Plants.

Work to be done in the FRUIT GARDEN.

Begin to inoculate Stone-fruits toward the Middle of the Month, doing it in an Evening, or in cloudy Weather: the firſt Sort, which is fit to Bud, is the Maſculine Apricock; and ſo proceed to the other Sorts, according to their Times of ripening their Fruits.

You muſt now look over your Wall and Eſpalier-trees again, and rub off all fore-right, ill-plac'd, or luxuriant Branches, and train the others regularly at equal Diſtances to the Wall or Eſpalier; but be not too officious with the Knife at this Seaſon, neither ſuffer any of the Leaves to be pull'd from the Branches, which will expoſe the Fruit too much to the Sun in the Day, and Cold in the Night.

Where Peaches and Nectarines have been left too cloſe together when they were thinn'd, they ſhould now be taken off, being careful not to ſuffer two or more Fruits to grow nearer than four or five Inches apart, which will greatly improve the Fruit, and ſtrengthen the Tree.

Look carefully after Snails and other Vermin, which infeſt your choice Fruit, and, if not timely prevented, will ſpoil it in a ſhort Time at this Seaſon.

In dry Weather water ſuch Trees as were tranſplanted the former Seaſon, obſerving to preſerve Mulch upon the Surface of the Ground about their Roots, to prevent their being dry'd by the Sun and Wind, and faſten thoſe Shoots which have been produc'd either to the Wall or Eſpalier, in the Order they ſhould grow; for if they are permitted to grow looſe, they will be in danger of being broken by Winds, *&c.*

Obſerve to keep the Ground about your Trees clear from Weeds and all other Plants; for if they are ſuffer'd to grow, they will exhauſt the Nouriſhment of the Ground, to the great Injury of the Trees, and the Fruits which ſuch Trees produce, will not be near ſo large, nor well taſted, as thoſe which are produc'd from Trees where no Plants are ſuffer'd to grow about them.

Your Vines ſhould now be look'd over again, and the Branches which are looſe muſt be faſten'd to the Wall; and all Side-ſhoots, or weak-trailing Branches, muſt be intirely diſplac'd, that the Fruit may enjoy the Benefit of the Sun and Air, which is abſolutely neceſſary to promote their Growth; but this is often neglected in many Gardens, and the Branches permitted to hang from the Wall, and entangle with each other, ſo that when they are put in their proper Places to the Wall, their Leaves will often have their back Parts upward, whereby the Fruit will be retarded, until they have obtain'd their proper Poſition again: And it is this Neglect which occaſions the late ripening or ill Taſte of the Fruit, and alſo renders the Wood ſoft and pithy, ſo that it ſeldom produces Fruit the following Year.

The Vineyard ſhould alſo be thus manag'd at this Seaſon, faſtening the Shoots to the Stakes in regular Order, ſo that each may equally have the Advantage of Sun and Air, and keep the Ground perfectly clear from all other Plants or Weeds, which if permitted to grow, would greatly prejudice the Vines.

Fruits in prime, or yet laſting.

Strawberries of ſeveral ſorts, Currants, Gooſeberries, Kentiſh, Duke, Flanders-heart, White-heart and Black-heart Cherries, Maſculine Apricock; and in the Forcing-frame, Peaches, Nectarines, and Grapes; and in the Hot-bed, Anana's or Pine-Apples.

Golden Ruſſet, Pile's Ruſſet, Stone-Pippen, Deux Anns or John-Apple, Oaken Pin, and ſome other Apples, where they are carefully preſerv'd.

As alſo the Black Pear of Worceſter, Lord Cheney's Green English Warden, and Bezy du Chaumontelle Pears.

Work to be done in the NURSERY.

You muſt obſerve in this Month (as was directed in the former) to keep the Ground between your Rows of Trees in the Nurſery intirely clear from Weeds, for theſe are very injurious to the Trees, and nothing can have a worſe Appearance, than a Nurſery over-grown with Weeds, therefore this Caution cannot be too often repeated: Obſerve alſo to keep the Seed-beds clear from Weeds.

Toward the latter End of the Month you muſt begin to bud Apricocks, and ſome early Peaches and Nectarines, but in this you muſt be guided by the Condition of the Trees from whence the Cuttings are taken; for if the Spring has prov'd very dry, the Buds will not eaſily part from the Shoot, in which Caſe it will be proper to defer this Work a little longer.

Obſerve to renew the Mulch about your new-planted Trees, where it is decay'd; for at this Seaſon, if the Weather proves dry, the Moiſture of the Earth will be exhaled, and the young Fibres will be dry'd up, where this Work is not carefully perform'd.

You may yet lay down the tender Shoots of Virgin's-bower, Granadilla's, *&c.* obſerving to water the Layers in dry Weather, which will greatly promote their taking Root. You may alſo make Layers of ſeveral hardy exotick Trees, which, if laid in the young Wood, will many of them take Root; ſo that whatever ſcarce Plants you have a mind to increaſe, may be tried this Way, ſince we are not aſſured what Plants will not take Root in this Management.

Trim up your Ever-greens according to the Uſes for which they are deſign'd, for if you ſuffer them to grow rude in Summer, they cannot be ſo ſafely reduc'd afterwards; beſides, the ruder they grow, the more naked they will be near their Stems.

Work to be done in the FLOWER GARDEN.

Tranſplant Annual Flowers out of the Hot-bed into the Borders of the Flower-Garden, ſuch as Capſicums, Balſamines, Convolvulus's, Love-Apple, Africans, French Marygolds, Amaranthus's, Indian Pinks, *&c.* obſerving to do it in a cloudy Day, or in an Evening, and give them ſome Water to ſettle the Earth to their Roots.

You muſt now lay down your Carnations, Pinks, Double Sweet-Williams, and ſuch other Fibroſe-rooted Plants, as are propagated by Layers, being careful to water them as ſoon as it is done ; but it muſt be given to them very gently, otherwiſe you will endanger the waſhing them out of the Ground, or breaking them, and this Watering ſhould be frequently repeated, which will greatly facilitate their Rooting.

This is a proper Seaſon for taking up and tranſplanting the Roots of Cyclamens, Fritillaria's, Dens Canis, Saffron, Narciſſus's, and ſuch other Bulboſe-rooted Flowers, as do not ſucceed well, if their Roots are kept any Time out of the Ground.

Cut off the Stalk of ſuch Flowers as have done blowing, and whoſe Stalks are decaying ; and tye up ſuch Flowers as are yet to blow, eſpecially your tall Autumnal Plants, which are often broken down by the Wind, if they are not timely ſupported with ſtrong Stakes.

Take up your Hyacinth-roots out of the Beds wherein they were laid the former Month to ripen ; and clear them from Filth, laying them upon a Mat in a ſhady Place to dry ; after which they may be put up into Drawers or Boxes, where they may enjoy the free Air, without which they will grow mouldy and decay.

It it now time to take up the Roots of Tulips, Anemonies and Ranunculus's, whoſe Leaves are decay'd, and ſpread them upon Mats in a ſhady Place to dry ; then clean them from Filth, and put them up in Boxes or Bags until the Seaſon for planting them, being careful to put them out of the Reach of Rats and Mice, otherwiſe they will eat them up.

Your Carnations which begin to break their Pods, ſhould be open'd in two or three different Parts, that their Flowers may expand equally on every Side, otherwiſe they will throw their Leaves out on one Side of the Pods : You muſt alſo obſerve to cover them with Glaſſes ſoon after their Pods are open, to ſkreen them from Moiſture, and the Heat of the Sun, both which are very injurious to them ; and look carefully after Ear-wigs and Ants, for if theſe can come at the Flowers, they will deſtroy them in a ſhort Time.

Tranſplant ſuch Sorts of Perennial of Biennial Fibroſe-rooted Plants, as were not done the former Month, into Nurſery-beds, where they ſhould be allow'd Room enough to grow till Autumn, which is the proper Seaſon for placing them in the Borders of the Flower-Garden to remain. Of theſe Kinds are French Honeyſuckles, Pinks, Sweet-Williams, Stock-Gilliflowers, Columbines, Dames Gilliflowers, Canterbury Bells, Hollyhocks, Scabious's, *&c.* all of which muſt be raiſed in the Flower-Nurſery the firſt Seaſon, and then brought into the Flower-Garden to blow.

Plant Cuttings of Lychnidea's, Double Sweet-Williams, Double Scarlet Lychnis's, Pinks and ſuch other Fibroſe-rooted Plants as you want to increaſe, which, if planted in a Bed of light rich Earth, and ſhaded and duly water'd, will take root very well.

Plants now in Flower.

Larkſpurs, White Lily, Orange Lily, red Day Lily, Everlaſting Pea, Sweet-ſcented Pea, Tangier Pea, Canada Golden Rod, Broad-leav'd up-right Dogsbane, Apocynum, Lilii convallii flore, yellow Aconite, horned Poppies of ſeveral Sorts, Capnoides, white, black and yellow Swallow-wort, Veronica's, Blattaria's, Scarlet Lychnis, Roſe Campion, Pinks, Double and Single Virgin's Bower, Flammula Jovis, Hyſſop, Clary's, Oriental Bugloſs, Double Ptarmica, Sweet Sultan, Xeranthemums, Coronilla herbacea flore vario, Jacea's, Santonina's, Acanthus, Snapdragons, Linarias, Tree Primroſe, Willow-weed or French Willow, yellow Loſeſtrife, purple Loſeſtrife, Valerianella Cornucopoides, Caltha Africana, Hieraciums, Chryſanthemums, Lychnis's, Nigella, Peach-leav'd Bell-flower, Lychnidea Caroliniana, Gentianella, white Wall-flower double and ſingle, white and red French Honeyſuckles, Lobel's Catchfly, Venus Navelwort, Flos Adonis, Venus Looking-glaſs, Double and Single Sweet-Williams, Double Catchfly, Bulboſe fiery Lily, Martagons ſeveral ſorts, Ornithogalums, Bulboſe Iris's, Bloody Cranesbill, red, white and Garden Valerian, Greek Valerian with blue and white Flowers, Oriental Ox-eye with yellow and white Flowers, Leucanthemums, red and white Batchelor's Button with double and ſingle Flowers, Double Ragged Robin, Savoy, and Tradeſcant's Spiderworts, Poppies of various Kinds, Columbines of various Colours, Spaniſh Figwort, Indian Scabious, ſeveral ſorts of Thrift, Candy Tuft, Dwarf Lychnis, Dwarf Annual Stock, Fox Gloves, Corn Flags two or three Sorts, white Hellebore, yellow Perennial and Tangier Fumitories, Sea Ragwort, Africans, Female Balſamine, Periwinkles, Fraxinella with purple and white Flowers, Great Blue Wolfsbane, Calcedonian Iris, Helianthemums, Sea Lavender's, Smilax, Phalangiums, Aſphodel's, Eupatoriums, Cyanus's of ſeveral Sorts, with ſome others of leſs Note.

Hardy Trees and Shrubs now in Flower.

Bladder Senna, Pomegranate with double and ſingle Flowers, Spaniſh Broom, Broad-leav'd yellow Jaſmine, white Jaſmine, Roſes of various ſorts, Tamariſk, Virginian Sumach, Dorycnium, Althæa fruteſcens Bryoniæ folio, Althæa fruteſcens flore parvo, Oleaſter, Frutex trifoliatus Ulmi Samarris, Nettle-tree, Upright Sweet Canada Raſpberry, Lime-tree, Shrub Cinquefoil, Tree Germander, Late-red, Dutch, Evergreen and Long-blowing Honeyſuckles, Spirea ſalicis folio, Cateſby's Climber, or Carolina Kidney-Bean-tree, Perennial Shrubby Lamium or Baſe Hore-hound, Syringa, Cytiſſus Lunatus, Mallow-tree, Tulip-tree, Scarlet-flowering Horſe Cheſnut, and ſome others of leſs Note.

Work to be done in the GREEN-HOUSE *and* STOVE.

Your Orange-trees, being now in Flower, ſhould be conſtantly ſupply'd with Water, to encourage them to ſet their Fruit, and the Earth on the Surface of their Tubs and Pots ſhould be ſtirr'd, and ſome rotten Neats-dung laid thereon, raiſing it round the Outſide of the Tubs or Pots, ſo as to make a Hollow to contain the Water ; but you ſhould never lay any new Dung upon the Pots, nor put any Dung into the Water to inrich it, as is by too many Perſons done, to the great Prejudice of their Trees ; for theſe ſtrongly impregnated Waters, inſtead of affording Nouriſhment to the Trees, do cauſe their their Leaves to change to a pale yellow Colour, and the Trees are apt to flower out of their proper Seaſon, which renders them weak, and many Times deſtroys them in two or three Years Time. The beſt Water for theſe Trees, is ſuch as is taken from Rivers or Ponds, where it is fully expos'd to the Sun and Air ; ſo that if you have no other than Spring or Well Water, it ſhould always be expos'd to the Sun and Air two or three Days before it is uſed. You muſt alſo gather off the Flowers as they blow, leaving but a few upon each Tree for Fruit, and thoſe upon the ſtrongeſt Branches, and where they are beſt ſituated to ſtand.

Plant Cuttings of Myrtles in a Bed of light rich Earth, obſerving to water and ſhade them until they have taken Root ; and now you may plant Cuttings of Geraniums, Cytiſſus's, and many other exotick Plants, which are ſhrubby, treating them in the Manner directed under their ſeveral Heads.

You may now ſhift any of your Green-houſe Plants into larger Pots, obſerving to pare off all the mouldy and decay'd Roots, which generally grow round next the Sides of the Pots, and take out as much of the old Earth from the Ball as you can conveniently without leaving their Roots too bare. When they are new-planted, they ſhould be placed in a ſhady Situation, and where they may be defended from ſtrong Winds, until they have taken new Root ; after which they may be removed to the Places where they are to remain during the Summer Seaſon.

Take off Cuttings from the ſeveral Kinds of Cereus's, Sedums, Euphorbiums, Ficoides's, Cotyledons, and other ſucculent Plants, laying them in a ſhady Part of the Stove for about a Fortnight, that their wounded Parts may heal over before they are planted, otherwiſe they will be in danger of rotting.

Stir up the Bark in thoſe Hot-beds which have been long made, and add ſome new Bark to them, which will renew their Heat, and plunge the Pots down again immediately : But this ſhould be done in ſoft, warm Weather, when there is little Wind, leſt by expoſing the Plants in cold Weather to the open Air, they ſhould ſuffer.

In fine Weather you ſhould give Air freely to your moſt tender exotick Plants, but it will be proper to ſhade the Glaſſes of the Stove in the Middle of the Day, when the Sun is very hot.

Tranſplant ſuch ſeedling exotick Plants as were rais'd in the Spring into larger Pots, and ſuch of them as are very tender, ſhould be plunged into a freſh Hot-bed, to promote their Growth ; but thoſe which are hardy will only require to be ſhelter'd until they have taken Root, after which Time they may be removed to the Places where they are to remain the Summer-ſeaſon.

You may now take up the Roots of the Canary Campanula, and all the Bulboſe Roots which come from the *Cape of Good Hope*, as the Hæmanthus, African Corn-Flag, blue Tuberoſe-rooted Hyacinth, Lilies, and ſeveral other Sorts whoſe Leaves are intirely decay'd, when they ſhould be parted and planted into Pots of freſh Earth immediately, placing them where they may have the Morning Sun till Eleven o' Clock, and give them now and then a little Water in very dry Weather; but do it ſparingly until they puſh forth new Leaves, for much Wet at this Seaſon, when the Roots are almoſt unactive, will rot them.

This is alſo a proper Seaſon for tranſplanting the Roots of the Guernſey and Belladonna Lilies, their Leaves being intirely decay'd; and at this Time freſh Roots ſhould be procur'd from abroad; for thoſe which are taken up after this Time, do ſeldom thrive ſo well. Theſe Roots ſhould be planted in Pots filled with the following Compoſt, *viz.* one third Part freſh Earth from a Paſture, a third Part of Sea Sand, and a third Part of Lime Rubbiſh. Theſe ſhould be well mix'd, and the Bottoms of the Pots cover'd with Stones, to make an open Paſſage for the Water to drain off; then fill the Pots with the Compoſt, and place the Roots therein, and ſet the Pots in a Situation where they may enjoy the Morning Sun, but give them little or no Water until their Leaves appear.

Your Tuberoſes which were planted early will now begin to flower, when they may be removed into Pots, (preſerving as much Earth as poſſible to their Roots) and placed where they are deſign'd to remain for flowering, obſerving to refreſh them often with Water; and thoſe which were planted later in order to ſucceed thoſe firſt planted, muſt have as much free Air as poſſible, and be frequently water'd, which will render them ſtrong, and cauſe them to produce a greater Quantity of Flowers.

The Anana's muſt now be frequently refreſh'd with Water, and in hot Weather ſhould have much free Air, for if the Glaſſes are kept too cloſe down, their Leaves will be ſcorch'd, to the great Prejudice of the Plants, and the Fruit will be leſs delicate; but if they have too much Water, and the Glaſſes left open in the Day-time, (as ſome have injudiciouſly done) the Plants will ſuffer as much that Way; for upon proportioning the Quantity of Air and Water equally, depends the whole Succeſs.

In the middle of this Month you may begin to take out of the Stove ſome of the hardier Sorts of Aloes, and other ſucculent Plants, placing them at firſt in a ſhady Situation, where Snails and other Vermin are not in too great Plenty, for when they are expos'd to the Violence of the Sun as ſoon as they are taken out of the Houſe, they change Colour, and appear unſightly, ſo they ſhould be inured to it by Degrees; and if Snails can come to them, they will gnaw their Leaves, and greatly deface them. After the Stove is thinn'd of ſome of theſe hardier Sorts, the others ſhould be placed at a greater Diſtance on the Stands, and cleaned from Filth, by which they will enjoy more Air, and be rendered ſtronger and more vigorous.

Plants now in Flower in the GREEN-HOUSE, GARDEN, *and* STOVE.

Oranges, Lemons, Limes, Citrons, and Shaddocks, Myrtles, Olives, Ciſtus halimi folio, Male Ciſtus of ſeveral ſorts, Ciſtus Ledon, Barba Jovis Africana, and Apocynum Africanum erectum ſalicis folio flore albo, Anemonoſpermos's ſeveral ſorts, Elichryſum flore aureo, Jaſminum Ilicis folio, Ketmia Papayæ folio, Cotton-plant, Ficoides's ſeveral Kinds, Indian yellow Jaſmine, Sedums ſeveral ſorts, Colutea Æthiopica Barbæ Jovis folio, Alcea Africana fruteſcens flore rubro, Barba Jovis or Silver Buſh, Dwarf American, Campanula, African Tree-Scabious, Baſſella, Melianthus two ſorts, Mimoſa, White Spaniſh Brooms, Cotyledons, Ricinoides folio multifido, Ricinoides Staphyſagriæ folio, Indian Arrow-root, Double Indian Naſturtium, Coffee-tree, Polygala Africana fruteſcens, Amomum Plinii, Aloes of ſeveral ſorts, Dwarf Pomegranate, Indian Flowering Reed, Cytiſſus lunatus, Phlomis's three or four ſorts, Cytiſſus Canarienſis, Geraniums of ſeveral ſorts, ſeveral ſorts of Paſſion-Flower, Plumeria, Caſſia's, Oleanders, Teucrium Bœticum, Lotus argentea Cretica, Lotus hæmorrhoidalis major & minor, Lilio-Narciſſus's, Pancratium, Abutilons, with ſome others.

JUNIPERUS, [is derived of *junior*, *younger*, and *pariens*, Lat. *bringing forth*; becauſe this Plant puts forth its young Fruits when other Berries are ripe] The Juniper-Tree.

The *Characters* are;

The Leaves are long, narrow, and prickly: The Male Flowers are in ſome Species produced at remote Diſtances from the Fruit on the ſame Tree, but in other Species they are produced on different Trees from the Fruit: The Fruit is a ſoft, pulpy Berry, containing three Seeds in each.

The *Species* are;

1. JUNIPERUS *vulgaris fruticoſa. C. B.* The common *Engliſh* Juniper.

2. JUNIPERUS *vulgaris arbor. C. B.* The Tree, or *Swediſh* Juniper.

3. JUNIPERUS *Virginiana. H. L. Folio ubique juniperino. Boerh. Ind.* The Cedar of *Virginiana.*

4. JUNIPERUS *Virginiana, foliis inferioribus juniperinis, ſuperioribus ſabinam, vel cypreſſum referentibus. Boerh. Ind.* Red *Virginian* Cedar.

5. JUNIPERUS *Virginiana, baccis albis.* The White-berry'd *Virginian* Cedar.

6. JUNIPERUS *Bermudiana. H. L.* The Cedar of *Bermudas.*

7. JUNIPERUS *minor montana, folio latiore, fructuque longiore. C. B. P.* Leſſer Mountain Juniper, with a broader Leaf, and a longer Fruit.

8. JUNIPERUS *major, baceâ cæruleâ. C. B. P.* Greater Juniper, with a blue Berry.

9. JUNIPERUS *major, baccâ rufeſcente. C. B. P.* Greater Juniper, with a reddiſh Berry.

10. JUNIPERUS *Cretica, ligno odoratiſſimo,* κέδρος *Græcorum recentiorum. Tourn. Cor.* Juniper of *Crete*, with a ſweet-ſcented Wood; which is the Cedar of the modern *Greeks.*

11. JUNIPERUS *latifolia arborea, ceraſi fructu. Tourn. Cor.* Broad-leav'd Eaſtern Tree Juniper, with a Cherry-ſhaped Fruit.

12. JUNIPERUS *orientalis, vulgari ſimilis, magno fructu nigro. Tourn. Cor.* Eaſtern Juniper, like the common Sort, with a large black Fruit.

The firſt of theſe Plants is very common upon dry Heaths in divers Parts of *England*, but has been introduced into Gardens, and was formerly in great Requeſt for Ever-green Hedges: Yet as it is very ſubject to decay in Patches, and thereby renders ſuch Hedges very unſightly, as alſo being very troubleſome to ſheer, they have been of late almoſt intirely rejected. But however improper theſe Trees may be for Hedges, or to clip into Pyramids or Balls, yet they may have a Place in ſmall Wilderneſs Quarters amongſt Ever-green Plants of low Stature, where, by their Diverſity, they will add to the Beauty of thoſe Plantations.

The ſecond Sort will grow to a larger Magnitude, ſometimes riſing to the Height of eighteen or twenty Feet: This may alſo be intermix'd with other Ever-green Trees of the ſame Growth, where, by its different-ſhap'd Leaves and Colour, it will increaſe the Beauty of ſuch Places.

Theſe Plants are both propagated by ſowing their Seeds, the beſt Seaſon for which is in *September* as ſoon as they are ripe; for if they are kept until Spring before they are ſown, they will not come until the ſecond Year. The Ground in which theſe Seeds are ſown ſhould be freſh and light, but it ſhould not be dung'd: It ſhould be well dug, and levell'd very even, then ſow your Seeds thereon pretty thick, and ſift ſome Earth over them about half an Inch thick: This Bed will require no farther Care, than only to keep it clear from Weeds; and toward the Middle or latter End of *April* you will find ſome of your Plants appear above Ground; tho' the greateſt Part of them perhaps may lie till the Spring following before they come up, at which Time you ſhould carefully clear the Beds from Weeds, and in very dry Weather refreſh them with ſome Water, which will greatly promote their Growth: In this Bed they ſhould remain till the following Spring, when you muſt prepare ſome Beds to tranſplant them into, which ſhould alſo be of light, freſh, undung'd Soil; and having well dug and cleans'd the Ground from all noxious Weeds and Roots, you ſhould make them level: Then, in the Beginning of *April*, which is the proper Seaſon for removing theſe Plants, you ſhould raiſe up the young ones with a Trowel, preſerving as much Earth as poſſible to their Roots, and plant them into the Beds about a Foot aſunder each Way, giving them ſome Water, to ſettle the Earth to their Roots: And if it ſhould prove very dry Weather, you may lay a little Mulch upon the Surface of the Ground round their Roots, which will be of great Service to the Plants.

In theſe Beds they may remain two Years, obſerving to keep them clear from Weeds; and in the Spring you ſhould ſtir the Ground gently between them, that their Roots may with greater Eaſe ſtrike into it; after which Time they ſhould be tranſplanted either into a Nurſery, at the Diſtance of three Feet Row from Row, and eighteen Inches aſunder in the Rows, or into the Places where they are to remain for good. The beſt Seaſon to tranſplant them (as I before obſerv'd) is in the Beginning of *April*; and you ſhould take 'em up carefully, to preſerve a Ball of Earth to their Roots; and when planted, their Roots ſhould be mulch'd: All which, if carefully attended to, as alſo obſerving to refreſh them with Water in very dry Weather, until they have taken new Root, will preſerve them from the Danger of not growing; and they being extreme hardy, in reſpect to Cold, will defy the ſevereſt of our Winters to injure them, provided they are not planted in a moiſt or rich Soil.

In order to have theſe Trees aſpire in Height, their under Branches ſhould be taken off, eſpecially where they are inclin'd to grow out ſtrong: But they muſt not be kept too cloſely prun'd, which would retard their Growth; for all theſe Ever-green Trees do more or leſs abound with a reſinous Juice, which in hot Weather is very apt to flow out from ſuch Places as are wounded: ſo that it will not be adviſeable to take off too many Branches at once, which would make ſo many Wounds from which their Sap in hot Weather would flow in ſuch Plenty, as to render the Trees weak and unhealthy.

The three Sorts of *Virginian Cedars* grow to a much greater Height than the former, and in their native Country afford excellent Timber for many Uſes; but with us there are very few which are above twenty or twenty-five Feet high: Tho' there is no doubt of their growing larger; for they thrive very faſt after the three firſt Years, and reſiſt the ſharpeſt Froſts of our Climate exceeding well, and are very apt to grow ſtrait and regular, provided they are not ſuffer'd to ſhoot out too much at Bottom.

Theſe Plants are alſo propagated by Seeds, which muſt be procured from *Virginia* or *Carolina*, (for they rarely produce ripe Seeds in *England)* and ſown as was directed for the other *Junipers:* But as this Seed can't be procur'd in *England* 'till Spring, ſo, when ſown at that Seaſon, it remains in the Ground until the ſucceeding Spring before the Plants appear; therefore you muſt obſerve to keep the Beds clear from Weeds, and not ſuffer the Seeds to be diſturb'd; which is often the Fault of ſome impatient People, who think, becauſe the Plants do not riſe the firſt Year, that they will never come up, and ſo dig up the Ground again, whereby their Seeds are buried; but if they are let remain, they ſeldom fail to grow. When the Plants are come up, they muſt be carefully weeded; and in dry Weather ſhould be refreſhed with Water, which will greatly forward their Growth; and the Spring following they ſhould be tranſplanted into Beds (as was directed for the common *Juniper)* in *April*, obſerving to preſerve a Ball of Earth to their Roots; and after they are planted, if the Seaſon be dry, they muſt be carefully water'd, and the Surface of the Ground cover'd with Mulch, to prevent the Sun and Wind from entering the Earth, to dry their Fibres: But they ſhould not be too much water'd, which often proves injurious to theſe Trees, by rotting their tender Fibres ſoon after they are emitted, whereby the Plants have been often deſtroy'd.

In theſe Beds they may remain two Years, obſerving to keep them clear from Weeds; and in Winter you ſhould lay a little freſh Mulch upon the Surface of the Ground round their Roots, which will prevent the Froſt from penetrating to them, and effectually preſerve them; for while the Plants are ſo young, they are liable to be impair'd by hard Froſts, when too much expos'd thereto; but when they have attain'd a greater Strength, they will reſiſt the ſevereſt of our Cold.

After two Years, they ſhould either be remov'd into a Nurſery, (as was directed for the common *Juniper)* or tranſplanted where they are deſign'd to remain; obſerving always to take them up carefully, otherwiſe they are ſubject to fail upon tranſplanting; as alſo to mulch the Ground, and water them as was before directed, until they have taken root; after which they will require no farther Care, than only to keep the Ground clear about their Roots, and to prune up their Side-branches to make them aſpire in Height.

The Soil in which you plant theſe Trees, ſhould be freſh and light, but muſt not be dung'd, eſpecially at the Time when they are planted; for Dung is very hurtful to them, eſpecially if it be not quite rotted to Mould; therefore the Mulch which is laid upon the Surface of the Ground ſhould not be Dung, but rather ſome freſh Turf cut from a Common, and the Graſs turn'd downward; which is certainly the beſt Sort of Mulching for moſt Plants, it affording no ill Scent, nor is it ſubject to breed Vermin, or be unſightly, and will effectually anſwer all the Purpoſes of Mulch, without any Danger of hurting the Plants.

Theſe Trees, being thus manag'd, will in a few Years riſe to a conſiderable Stature, and, by the Variety of their Evergreen Leaves, and Manner of Growth, will greatly add to the Beauty of ſuch Plantations, if rightly diſpoſed; which indeed is what we ſeldom obſerve in any of the *Engliſh* Gardens or Wilderneſſes; for there are few People who conſider the different Growths of the ſeveral Trees with which they compoſe ſuch Plantations, ſo as to place the talleſt growing Trees the backwardeſt from Sight, and the next Degree to ſucceed them, and ſo gradually diminiſhing till we come to the Common *Juniper*, and others of the ſame Growth, whereby all the Trees will be ſeen, and the gradual Declivity of their Tops will appear like a verdant Slope, and be much more agreeable to the Sight, as alſo more advantageous to the Growth of the Trees, than to place Shrubs of humble Growth near ſuch Plants as will grow to the firſt Magnitude, whereby the Shrub is hid from Sight, and will be over-ſhadow'd and deſtroy'd: nor can the Diſtance which each Tree requires, be ſo juſtly proportion'd any other way; for in this Diſtribution, the largeſt Trees being ſeparated by themſelves, may be planted at a due Diſtance; and then thoſe of a middling Growth ſucceeding, may be accordingly allowed ſufficient Room; and the ſmaller, which are next the Sight, being plac'd much cloſer, will hide the naked Stems of the larger Trees, and have an agreeable Effect upon the Sight.

The Timber of theſe Trees is of excellent Uſe in *America* for building of Veſſels, wainſcotting Houſes, and for making many Sorts of Utenſils, it abounding with a bitter Reſin, which prevents its being deſtroy'd by Vermin; but it is very brittle, and ſo not proper for ſtubborn Uſes: but however, by increaſing the Number of our Timber Trees, we ſhall find many Advantages, beſides the Pleaſure their Variety affords; for we may hereby have Trees of very different Kinds, which are adapted to grow in various Soils and Situations, whereby we ſhall never want proper Trees for all the different Sorts of Soils in *England*; if proper Care be taken in their Choice; which would be a great Improvement to many Parts of this Kingdom, which now lie unplanted, becauſe the Owner, perhaps, finds that neither *Oaks* nor *Elms* will thrive there, and ſo conſequently concludes that no other Sort will: which is a great Miſtake; for if we conſider how different the Structure of Trees is, (being deſign'd by the wiſe Author and Contriver of all Things, to grow on different Soils and Situations) and only obſerve what Sorts are adapted for growing upon dry, barren Mountains, and what are deſign'd for the lower and richer Valleys, we need never be at a Loſs for proper Trees for all Sorts of Ground.

The *Bermudas Cedar* coming from a more temperate Climate, is ſomewhat tenderer than the former, and more impatient of our Cold, (eſpecially while the Plants are young) but afterwards it endures it very well, as may be ſeen by divers Trees which are now growing in *England*, ſome of which are upward of twenty Feet high, and have reſiſted ſeveral ſevere Winters without Injury: but theſe *Cedars* are not of ſo quick a Growth here, as in a more temperate Climate; for in their native Country they will grow to be large enough for Ship Timber in twenty Years, from Seed, (as I have been credibly inform'd by ſeveral Perſons who have lived there many Years): however, when they have been ſome time naturalized to our Country, there is no doubt but they will thrive much better than at preſent, eſpecially when the Trees here produce Berries; for the young Plants raiſed therefrom will be much hardier than thoſe procured from foreign Seeds, as is evident in many other Kinds.

Theſe Plants are propagated by Seeds in the ſame Manner as the former, with only this Difference, that theſe ſhould be ſown in Tubs or Pots of Earth, that they may be remov'd into Shelter in Winter-time, otherwiſe the young Plants are often hurt by hard Froſts: but they will require no more Care than only to be placed under a common Hot-bed Frame, that the Glaſſes may be conſtantly kept off in mild Weather, when they can't have too much free Air, and only cover'd in hard Froſts. Theſe Seeds do conſtantly remain in the Ground until the ſecond Year, before they come up, therefore the Earth in the Pots ſhould not be diſturb'd; and in the Summer-time they ſhould be plac'd in the Shade, to prevent the Earth from drying too faſt; and in very dry Weather they ſhould be often water'd; but do not give too much Water to them at once, which would rot the Seeds.

The Spring following, when the young Plants come up, they muſt be carefully clear'd from Weeds, and in dry Weather refreſh'd with Water; but ſhould ſtand, during the Summer-ſeaſon, in a Place defended from ſtrong Winds; and in Winter muſt be plac'd into Shelter, where they may be cover'd in hard froſty Weather, but muſt have open Air when the Weather is mild. In *April* following you ſhould tranſplant them each into a ſingle Half-penny Pot fill'd with rich light Earth, being careful to raiſe them up with a Ball of Earth to their Roots; and when they are planted, you ſhould water them, to ſettle the Earth to their Roots; then place the Pots in a warm Situation, where they may be defended from Sun and Wind: but if you will beſtow a moderate Hot-bed to plunge the Pots upon, it will greatly promote their taking new Root: however, you muſt carefully defend them from the great Heat of the Sun, which is injurious to them when freſh remov'd; but when they have taken Root, you may expoſe them by Degrees to the open Air: If you ſuffer the Pots to remain plung'd all the Summer, it will preſerve the Earth therein from drying ſo faſt as it would do, if they were ſet upon the Ground.

In *October* you ſhould again remove theſe Pots into Shelter, or elſe plunge their Pots into the Ground under a warm Hedge, where they may be protected from the cold North and Eaſt Winds; and in the Spring following you muſt ſhift the Plants into Pots a Size bigger, taking away ſome of the Earth from the Outſide of the Ball, and adding ſome freſh, which will promote their Growth; and ſo continue to manage them as was before directed, until you plant them out in the Places where they are deſign'd to remain; which ſhould not be done till they are three or four Years old, by which time they will be ſtrong enough to bear the Cold.

The Reaſon for my directing theſe Plants to be preſerv'd in Pots until they are planted out for good, is, becauſe they are difficult to tranſplant; and being tender, will require ſome Shelter while young; and whoever obſerves the Method here laid down, will find the Plants ſo manag'd to gain two Years Growth in ſix, from thoſe rais'd in the open Air, and be in leſs Danger of being deſtroy'd: And as the Trouble and Expence in raiſing 'em this way is not great, ſo it is worth practiſing, ſince in a few Years the Trees will recompence the Trouble.

Theſe Plants ſhould have a freſh, light, undung'd Soil, as the former, and may be plac'd in Plantations with them, obſerving to let theſe be plac'd in a Line below thoſe; for they will not grow ſo faſt with us as they do, nor do I believe they will make ſuch large Timber; tho' this is much preferable to the Timber of the other Sorts.

The Timber of this Tree is of a reddiſh Colour, and very ſweet, and is commonly known in *England* by the Name of *Cedar Wood*, tho' there are divers Sorts of Wood call'd by that Name, which come from very different Trees, eſpecially in the *Weſt-Indies*, where there are ſeveral Trees of vaſtly different Appearances, which have that Appellation; it is this Sort of Wood which is uſed for Pencils, as alſo to wainſcot Rooms, and making Stair-caſes, it enduring longer ſound than moſt other Sorts of Timber; which, perhaps, may be owing to ſome extreme bitter Taſte in the Reſin, with which the Tree abounds; for it is very remarkable, that the Worms do not eat the Bottoms of the Veſſels built with this Wood, as they do thoſe built with *Oak*; ſo that the Veſſels built with *Cedar* are much preferable to thoſe built with any other Sort of Timber, for the Uſe of the *Weſt-India* Seas; but they are not fit for Ships of War, the Wood being ſo brittle as to ſplit to pieces with a Cannon Ball; but when well poliſh'd, and neatly fitted up in Wainſcot, it appears very handſome, and will be found a valuable Timber in *England*.

The ſeventh Sort grows in great Plenty in the *Alpes*, and alſo on the Hills in *Germany*. The eighth Sort grows wild in the *Pyrenean* Mountains, and alſo on ſome Hills in the *South* of *France*. The ninth Sort grows plentifully in *Spain*, from whence the Berries have been brought to *England*, and many Plants have been raiſed. The tenth, eleventh, and twelfth Sorts were diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent their Berries to the *Royal Garden* at *Paris*. The tenth Sort hath a ſweet-ſcented Wood, ſomewhat like that of *Bermudas*, and is by the modern *Greeks* called *Cedar*.

The ſix laſt Sorts may be propagated by ſowing of their Berries early in the Spring, on Borders of light freſh Earth, which are expoſed to the Morning-Sun, covering them about half an Inch thick with light Earth. Theſe Berries will remain in the Ground one whole Year, ſo that during that time the Ground ſhould be kept clear from Weeds, and in very dry Weather the Borders ſhould be now and then watered. The following Spring the Plants will begin to appear, when they muſt be kept very clear from Weeds, and in dry Weather they ſhould be duly watered. With this Management the Plants will make a conſiderable Advance the firſt Seaſon, ſo that they will be fit to tranſplant the following Spring; when you ſhould prepare ſome Beds of freſh Earth in a ſheltered Situation, into which the Plants muſt be removed juſt before they begin to ſhoot, and planted about a Foot aſunder every way. In doing of this great Care ſhould be taken not no break or tear the Roots of the Plants, and alſo to plant them as ſoon as poſſible, for if they remain but two or three Hours out of the Ground, their Roots will dry, and the Plants rarely ſurvive their Removal. This Work ſhould alſo be done in moiſt or cloudy Weather, when the Air is ſoft; for if it is done when the dry Eaſterly Winds reign, the Plants ſeldom thrive. When they are planted, the Surface of the Ground about their Roots ſhould be covered with Mulch, to prevent the Sun and Wind from penetrating the Earth to their Roots, which, if not prevented, will deſtroy the Plants. In dry Weather they ſhould be now and then gently watered; but they ſhould by no means have too great a Quantity of Moiſture; for that will rot their tender Fibres, and deſtroy the Plants.

In theſe Beds the Plants ſhould remain two Years, during which Time the Ground ſhould be kept conſtantly clear from Weeds; and the Spring after tranſplanting, the Ground ſhould be gently dug, to looſen it, being careful not to expoſe the Roots of the Plants to the Air. And at the two Years End, they may be removed to the Places where they are deſigned to remain, provided the Ground is ready; but if the Plantation is not laid out, then the Plants ſhould be removed into a Nurſery, for a Year or two longer, placing them in Rows three Feet apart, and the Plants two Feet aſunder in the Rows. This ſhould alſo be done in the Spring, juſt before they begin to ſhoot; and the ſame Care ſhould be had to mulch their Roots as before, as alſo to do the Work in moiſt and cloudy Weather. When the Plants have taken Root either in the Nurſery, or in the Plantation where they are deſigned to remain, they will require no other Care but to keep them clear from Weeds, until the Plants are grown ſtrong enough to bear down the Weeds, and keep them under.

The eighth, ninth, and tenth Sorts riſe to a great Height, and will grow to a pretty large Size; ſo theſe ſhould be planted amongſt other Ever-green-trees of the ſame Growth, where they will afford an agreeable Variety; for they are naturally diſpoſed to grow in a pyramidal Form, ſomewhat like the *Cypreſs*; and may be planted round Buildings, where they will make a fine Appearance. They are all of them hardy enough to reſiſt the Cold of our Winters, and will grow on ſtony cold Lands.

The ſeventh, eleventh, and twelfth Sorts are of humbler Growth, ſo may be planted amongſt lower evergreen Shrubs, in Front of the larger Trees, where they may be placed ſo as to render them very beautiful, and greatly to add to the Variety. The ſeventh Sort ſeldom riſes above a Foot high; but the others will grow to the Height of five or ſix Feet, and have nearly the ſame Appearance with our common *Juniper*.

JUSTICIA.

This Plant was ſo named by the late Dr. *Houſtoun*, in Honour to *James Juſtice*, Eſq; a great Lover and Encourager of Gardening and Botany.

The *Characters* are;

It hath an anomalous Flower conſiſting of one Leaf, which is divided into two Lips almoſt to the Bottom, the under one being for the moſt part intire, but the upper Lip is divided into two; the Flowers are ſucceeded by inverſed ſpear-ſhaped Fruit, which have one Cell, containing many flat Seeds.

The *Species* are;

1. JUSTICIA *annua, hexangulari caule, foliis circææ conjugatis, flore miniato. Houſt.* Annual Juſticia, with an hexangular Stalk, Enchanters Night-ſhade Leaves growing oppoſite, and a carmine Flower.

2. JUSTICIA *fruteſcens, floribus ſpicatis majoribus, uno verſu diſpoſitis. Houſt.* Shrubby Juſticia, with larger Flowers growing in Spikes, appearing on one Side of the Stalk.

Theſe two Plants were diſcovered by the late Dr. *Houſtoun*, at *la Vera Cruz*, from whence he ſent the Seeds and Specimens to *England*. The firſt Sort grows about two or three Feet high, and periſhes ſoon after the Seeds are ripe; but the ſecond Sort grows to the Height of ſix or ſeven Feet, and divides into many Branches, which become woody; at the End of the Branches the Flowers are produced in Spikes, which are of a carmine Colour.

Theſe Plants may be propagated by Seeds, which ſhould be ſown early in the Spring in ſmall Pots filled with light freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water the Earth gently as it appears dry, and alſo to cover the Glaſſes of the Hot-bed every Night, to preſerve a kindly Warmth in the Bed. When the Plants begin to appear, the Weeds ſhould be carefully pulled out of the Pots, and the Glaſſes of the Hot-bed ſhould be raiſed every Day when the Weather is warm, to admit freſh Air to the Plants; but if the Nights are cold, the Glaſſes ſhould be duly covered with Mats ſoon after the Sun is gone off from the Bed. The Plants muſt alſo be frequently watered in warm Weather; but it ſhould not be given to them in large Quantities while the Plants are young, becauſe they are then very tender, and ſubject to rot at the Bottom of their Stems, with much Moiſture.

When the Plants are about two Inches high, they ſhould be carefully taken up, and each tranſplanted into a ſeparate ſmall Pot filled with light freſh Earth, and then plunged into the Hot-bed again, being careful to water and ſhade the Plants until they have taken new Root; after which Time they ſhould have Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and they ſhould be duly watered every Day in hot Weather.

As the Plants advance in their Growth, ſo they ſhould be ſhifted into larger Pots; for if their Roots are too much confined, the Plants will not make any conſiderable Progreſs; but they ſhould not be over-potted, for that will be of worſe Conſequence than under-potting of them; for when they are planted in very large Pots, they will ſtarve and decay, without producing any Flowers. Theſe Plants are too tender to endure the open Air in this Country, therefore they ſhould always remain in the Hot-bed, being careful to let them have a due Proportion of Air in hot Weather: and the annual Sort ſhould be brought forward as faſt as poſſible in the Spring, that the Plants may flower early, otherwiſe they will not produce good Seeds in *England*.

The ſecond Sort ſhould remain in the Hot-bed during the ſummer Seaſon (provided there be Room under the Glaſſes, without being ſcorched); but at *Michaelmas*, they ſhould be removed into the Stove, and plunged into the Bark-bed; where they muſt remain during the Winter Seaſon, obſerving to keep them warm, as alſo to water them gently two or three Times a Week, according as they ſhall require. The following Summer theſe Plants will flower, and will abide ſeveral Years; but they rarely produce good Seeds in *Europe*.

KA

KALI, [is an *Aſiatick* Name, which ſignifies a Sea-Plant] Glaſs-wort.

The *Characters* are;

It hath a Flower conſiſting of many Leaves, which are placed in a Circle, and expand in form of a Roſe: out of the middle of which riſes the Pointal, which afterward becomes an almoſt globular membranaceous Fruit, containing one ſingle Seed, which is twiſted like a Periwinkle, and generally infolded in the Leaves of the Flower.

The *Species* are;

1. KALI *majus, cochleato ſemine. C. B. P.* Snail-ſeeded Glaſſwort.
2. KALI *ſpinoſum, foliis longioribus & anguſtioribus. Tourn.* Prickly Glaſſwort, with longer and narrower Leaves.
3. KALI *ſpinoſum, foliis craſſioribus & brevioribus. Tourn.* Prickly Glaſſwort, with thicker and ſhorter Leaves.
4. KALI *Siculum lignoſum, floribus membranaceis. Bocc. Rar. Plant.* Sicilian ligneous Glaſſwort, with membranaceous Flowers.
5. KALI *fruticoſum Hiſpanicum, tamariſci folio. Tourn.* Shrubby Spaniſh Glaſſwort, with a Tamariſk Leaf.
6. KALI *fruticoſum Hiſpanicum, geniſtæ fronde. Tourn.* Shrubby Spaniſh Glaſſwort, with Broom-tops.
7. KALI *fruticoſum Hiſpanicum, capillaceo folio villoſo. Tourn.* Shrubby Spaniſh Glaſſwort, with a hairy and downy Leaf.
8. KALI *foliis longioribus & anguſtioribus ſubhirſutis. Tourn.* Glaſſwort, with longer and narrower ſomewhat hairy Leaves.
9. KALI *orientale fruticoſum ſpinoſum, camphoratæ folio. Tourn. Cor.* Eaſtern ſhrubby prickly Glaſſwort, with a ſtinking ground-pine Leaf.
10. KALI *orientale fruticoſum, flore maximo albido. Tourn. Cor.* Eaſtern ſhrubby Glaſſwort, with a very large whitiſh Flower.
11. KALI *orientale fruticoſum, foliis ſedi minoris, flore purpureo. Tourn. Cor.* Eaſtern ſhrubby Glaſſwort, with Leaves like the leſſer Houſleek, and a purple Flower.
12. KALI *orientale fruticoſum altiſſimum, florum ſtaminibus purpureis. Tourn. Cor.* The talleſt ſhrubby Eaſtern Glaſſwort, with Flowers having purple Stamina.
13. KALI *orientale fruticoſum lanuginoſum. Tourn. Cor.* Woolly Eaſtern ſhrubby Glaſſwort.
14. KALI *orientale fruticoſum, linariæ folio. Tourn. Cor.* Eaſtern ſhrubby Glaſſwort, with a toad-flax Leaf.
15. KALI *orientale fruticoſum, flore magno purpureo. Tourn. Cor.* Shrubby Eaſtern Glaſſwort, with a large purple Flower.
16. KALI *orientale fruticoſum, floribus albis. Tourn. Cor.* Shrubby Eaſtern Glaſſwort, with white Flowers.
17. KALI *orientale ſpinoſum ſubhirſutum, tenuiſſimo folio. Tourn. Cor.* Prickly Eaſtern hairy Glaſſwort, with a very narrow Leaf.
18. KALI *orientale, capillaceo folio, flore purpuraſcente. Tourn. Cor.* Eaſtern Glaſſwort, with a capillaceous Leaf, and a purpliſh Flower.

The firſt Sort here mentioned grows wild in the *Mediterranean* in ſeveral Places, where it is gathered for the making *Sode*, which is a ſort of Pot-aſh uſed in the making of Soap. It is alſo cultivated in the South of *France*, in ſalt Marſhes, for the ſame Purpoſe. This Plant ſeldom grows large, unleſs it is cultivated, which greatly improves its Size, ſo that it often grows from two to three Feet high, and divides into many Branches, whereas in the natural Places of its Growth, it is ſeldom above a Foot high. The *Spaniards* alſo cultivate ſeveral of the Species here mentioned, in order to make *Sode* thereof, the beſt of which is brought from *Alicant* and *Cartagena*. I believe moſt of the Sorts may be uſed indifferently for the making Pot-aſh; for in the ſeveral Countries, from whence we have the Pot-aſh, it is made of different Sorts. But the beſt *Pot-aſh* is that which comes from the *Levant*, which is called *Barillia*; the Salt of theſe Aſhes are clear and white, ſo is uſed in making of the fineſt Glaſs, and the hardeſt Soap. But this is made of a different Plant from any of this Genus, and is before mentioned under the article *Ficoides*.

The Inhabitants of thoſe warmer Countries, who cultivate theſe Plants, ſow their Seeds early in the Spring, on low marſhy Grounds near the Sea, or on ſalt Ponds, where the Plants ſoon come up, and in about three Months will be fit to cut for Uſe; when they mow it down, and dry it after the manner of Hay. When it is well dried, they dig Holes or Pits, in the nature of *Lime-Kilns*; then they ſet Fire to a Bundle of the Herb, which they throw into the Pit; and after that they throw three or four more Bundles into the Pit, which they ſuffer to be well lighted; then they fill the Pit with the dried Herb, and ſtop the Top of it up, leaving it to conſume for ſome Time, to be reduced to Aſhes. When they open the Pit, they find the Salt incorporated into a ſolid Rock, which they are obliged to break and raiſe up as Stones out of a Quarry.

There are ſome ſorts of Pot-aſh, which are made of many Kinds of Sea-weeds; but theſe are very little eſteemed; they may be eaſily known by their dark Colour, and fetid Scent, as alſo by their Moiſture.

The third and fourth Sorts of Glaſſwort grow at a greater Diſtance from the Sea: Theſe are frequently preſerved in Botanic Gardens, for Variety, as are ſome of the other *Species*, tho' there are not many Kinds which will perfect their Seeds in *England*. All the Kinds are propagated by Seeds, which ſhould be ſown the Beginning of *March*, on a Bed of freſh light Earth in an open Situation; and when the Plants come up, the Weeds ſhould be carefully drawn out from amongſt them; and where the Plants are too cloſe, they ſhould be thinned, ſo as to leave them about ſix or eight Inches aſunder every way: as the Plants advance, ſo they ſhould be kept clear from Weeds; and the laſt Time of thinning of the Plants, they ſhould be left a Foot aſunder, which will be ſufficient Room for any of the Sorts to grow to Maturity. Theſe Plants flower in *July* and *Auguſt*, and if the Autumn proves warm, ſome of the Sorts will produce ripe Seeds about *Michaelmas*.

As theſe Plants do not bear Tranſplanting, ſo where they are cultivated for Uſe, the beſt Method will be to hough the Plants ſoon after they come up, as is practiſed for *Turnips*, *Carrots*, and ſeveral other eſculent Plants, which will deſtroy the Weeds, when it is carefully performed in dry Weather; and by ſtirring of the Ground between the Plants, it will occaſion their growing much larger than where this is not practiſed. But as our Seaſons in *England* are ſeldom warm enough to bring theſe Plants to Perfection, ſo it is not worth the Trouble of cultivating here. In ſome of the *Engliſh* Colonies in *America*, this Commodity may pay the Inhabitants very well, if they would cultivate it; but then I ſhould adviſe the ſowing the *Barillia* only, which is the moſt valuable Kind.

KARATAS, The Penguin or wild Ananas.

The *Characters* are;

It hath a tubulous bell-ſhaped Flower, which is divided into three Parts at the Mouth; from whoſe Calyx ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower; which afterward

terward becomes a fleſhy almoſt conical Fruit, which is divided by Membranes into three Cells, which are full of oblong Seeds.

There is but one Sort of this Plant at preſent known, which is;

Karatas *foliis altiſſimis, anguſtiſſimis & aculeatis. Plum. Nov. Gen.* The wild Ananas or Penguin.

Father *Plumier* has made a great Miſtake in the Figure and Deſcription of the Characters of this Plant, and the *Caraguata*; for he has joined the Flower of the *Caraguata* to the Fruit of the *Karatas*, and *vice verſa*.

This Plant is very common in the *Weſt-Indies*, where the Juice of its Fruit is often put into *Punch*, being of a ſharp acid Flavour. There is alſo a Wine made of the Juice of this Fruit, which is very ſtrong; but it will not keep good very long, ſo is only for preſent Uſe. This Wine is very intoxicating, and heats the Blood; therefore ſhould be drank very ſparingly.

In *England* this Plant is preſerved as a Curioſity; for the Fruit ſeldom arrives to any Degree of Perfection in this Country; and if it were to ripen as thoroughly here, as in its native Country, it would be little valued on account of its great Auſterity; which will often take the Skin off from the Mouths and Throats of thoſe People, who eat it incautiouſly.

This Plant is propagated by Seeds; for tho' there are often Suckers ſent forth from the old Plants, yet they coming between the Leaves, are ſo long, ſlender, and ill-ſhapen, that if they are planted, they ſeldom make regular Plants. Theſe Seeds ſhould be ſown early in the Spring, in ſmall Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving if the Nights ſhould prove cold, to cover the Glaſſes with Mats, to keep the Bed in a due Temper of Heat; as alſo gently to water the Earth, as often as it appears dry. When the Plants are come up, they ſhould be carefully cleared from Weeds; and in the Day-time the Glaſſes of the Hot-bed ſhould be raiſed, to admit freſh Air to the Plants, that they may not draw up too weak; they muſt alſo be frequently refreſhed with Water. When the Plants are ſtrong enough to tranſplant, they ſhould be carefully taken up, each planted into a ſeparate Pot, filled with light rich Earth, and plunged into the Hot-bed again, obſerving to refreſh them frequently with Water, until they have taken new Root; after which Time they ſhould have Air and Water in proportion to the Warmth of the Seaſon. In this Bed the Plants may remain till *Michaelmas*, at which Time they ſhould be removed into the Stove, and plunged into the Bark-bed, where they ſhould be treated in the ſame Manner as the *Ananas*.

Theſe Plants will not produce their Fruit in *England*, until they are three or four Years old; ſo they ſhould be ſhifted into larger Pots, as the Plants advance in their Growth; for if their Roots are too much confined, they will make but little Progreſs. They ſhould alſo be placed at a pretty great Diſtance from each other; for their Leaves will be three or four Feet long, which turning downward, occupy a large Space.

A KATKIN, is an Aggregate of Summits, hanging down in Form of a Rope, or Cat's Tail, as in the *Sallow*, *Haſel*, *Birch*, &c. and is call'd in Latin *Iulus*.

KEMPFERA.

This Plant was ſo named by the late Dr. *Houſtoun*, in Honour to the Memory of Dr. *Kempfer*, a Learned Botaniſt.

The *Characters* are;

It hath an anomalous Flower conſiſting of one Leaf and divided at the Brim into five Parts: after the Flower is parted, the Pointal becomes a hard Fruit, which is divided into four Cells, which are full of ſmall Seeds.

We know but one Sort of this Plant, *(viz.)*

Kempfera *fruteſcens, chamædryos folio, floribus ſpicatis cœruleis. Houſt.* Shrubby Kempfera, with a *Germander* Leaf; and blue Flowers growing in a Spike. This Plant is figured and deſcribed in the *Paradiſus Batavus*, under the Title of *Veronicæ ſimilis fruticoſa Curaſſavica, teucrii foliis, flore galericulato*.

It is very common in *Jamaica*, and ſeveral other Iſlands in the *Weſt-Indies*, where it grows to the Height of three or four Feet, and becomes woody. The Flowers are produced in Spikes at the Extremity of the Branches, which are of a fine blue Colour.

This Plant is propagated by Seeds, which ſhould be ſown early in the Spring, in Pots filled with light rich Earth, which muſt be plunged into a Hot-bed of Tanners-bark, where they muſt be kept warm, and frequently refreſhed with Water. In about five Weeks the Plants will begin to appear; when they muſt be carefully cleared from Weeds, and duly watered; but this muſt be done very gently, becauſe the Plants are very tender while they are young. In the middle of the Day, the Glaſſes of the Hot-bed ſhould be raiſed to admit freſh Air to the Plants, to prevent their drawing up too weak; but if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered with Mats, ſoon after the Sun is gone off the Bed, to keep the Bed in a due Temperature of Warmth. When the Plants have obtained ſufficient Strength to tranſplant, they ſhould be carefully turned out of the Seed Pots, and parted, placing each into a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to water them pretty well to ſettle the Earth to their Roots, as alſo to cover the Glaſſes every Day with Mats, to ſcreen the Plants from the Sun, until they have taken new Root, after which Time they ſhould have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon; and they muſt be frequently watered in hot Weather, for they naturally grow on moiſt Places.

In this Hot-bed the Plants may remain during the Summer Seaſon; but at *Michaelmas*, they ſhould be removed into the Stove, and plunged into the Bark-bed, where they muſt be kept very warm during the Winter Seaſon, for they are very impatient of Cold; they ſhould alſo be frequently refreſhed with Water, but it muſt be given to them in ſmall Quantities during the cold Weather; for they are very ſubject to rot with too much Moiſture at that Seaſon. In the Spring of the Year the Plants may be removed into a freſh Hot-bed of Tanners-bark, which will greatly forward their Growth; but there ſhould be great Care the Bed be not too hot, leſt it ſcorches their Roots. If the Plants thrive well the firſt Seaſon, they will flower the ſecond Summer; but they ſeldom produce good Seeds in this Country, however the Plants may be maintained ſeveral Years, with proper Care.

KETMIA, [is a *Syriack* Word: It is commonly call'd *Althæa arboreſcens.*]

The *Characters* are;

The Flower is compoſed of one intire Leaf, which expands in the Form of thoſe of the common Mallow: *The Fruit is oblong, and divided into ſeveral Cells, in each of which are contain'd ſeveral roundiſh Seeds.*

The *Species* are;

1. Ketmia *Syrorum, quibuſdam. C. B. Althæa frutex*, with red Flowers.

2. Ketmia *Syrorum, flore purpureo-violaceo. Tourn. Althæa frutex*, with purple Flowers.

3. Ketmia *Syrorum, flore albo. Boerh. Ind. Althæa frutex*, with white Flowers.

4. Ketmia *Syrorum, floribus ex albo & rubro variis. Tourn. Althæa frutex*, with ſtriped Flowers.

5. Ketmia *Syrorum, foliis ex albo eleganter variegatis. Cat. Plant. Hort. Lond. Althæa frutex*, with ſtriped Leaves.

6. Ketmia *Sinenſis, fructu ſubrotundo, flore ſimplici. Tourn.* China Roſe, *vulgo*.

7. Ketmia *Sinenſis, fructu ſubrotundo, flore pleno. Tourn.* Double China Roſe, *commonly called* in the *Weſt-Indies*, Martinico Roſe.

8. Ketmia *Virginienſis, folio inferiori ulmi, ſuperiori aceris. Boerh. Ind.* Virginian *Ketmia*, with under Leaves like the *Elm*, and upper Leaves like *Maple*.

9. Ketmia *Carolinienſis, folio ribeſii, flore amplo flaveſcente, fundo purpureo.* Carolina *Ketmia*, with Currant Leaves, and an ample yellowiſh Flower with a purple Bottom.

10. Ketmia *Carolinienſis, folio oblongo magis acuminato, flore amplo purpureo.* Carolina *Ketmia*, with a long ſharp-pointed Leaf, and an ample purple Flower.

11. Ketmia *Americana, folio papayæ, flore magno flaveſcente, fundo purpureo, fructu erecto pyramidali, hexagono, ſemine rotundulo, ſapore fatuo. Boerh. Ind.* American *Ketmia*, with a Papaw Leaf, and a large yellowiſh Flower with a purple Bottom, an hexagonal pyramidal Pod growing upright, and roundiſh Seeds.

12. Ketmia *Indica, vitis folio ampliore. Tourn.* Indian *Ketmia*, with an ample Vine-Leaf.

13. Ketmia *Ægyptiaca, ſemine moſchato. Tourn.* Egyptian *Ketmia*, with Seeds ſmelling like Muſk, *commonly called* in the *Weſt-Indies*, Muſk-ſeed.

14. KETMIA *Indica aculeata, foliis digitatis. Tourn.* Indian *Ketmia*, with rough-finger'd Leaves.

15. KETMIA *Indica, goſſypii folio, acetoſæ ſapore. Tourn. Capſula ſeminali rubra.* Indian *Ketmia*, with a Cotton Leaf, whoſe Fruit taſtes like Sorrel, *commonly called* in the *Weſt-Indies*, Indian *or* Red Sorrel.

16. KETMIA *Indica, goſſypii folio, acetoſæ ſapore, capſula ſeminali albida.* Indian *Ketmia*, with a Cotton Leaf, and a whitiſh Seed-veſſel, taſting like Sorrel, *commonly called*, White Sorrel.

17. KETMIA *Braſilienſis, folio ficus, fructu pyramidato ſulcato. Tourn.* Braſil *Ketmia*, with a Fig-Leaf, and a pyramidal furrow'd Fruit, *commonly called* in the *Weſt-Indies*, Okra.

18. KETMIA *Indica, folio ficus, fructu pentagono recurvo eſculento, graciliore & longiore.* Indian *Ketmia*, with a Fig-Leaf, and a five-corner'd, long, ſlender, eatable Fruit, recurv'd at the Top, *commonly called* in the *Weſt-Indies*, Long Okra.

19. KETMIA *veſicaria vulgaris. Tourn.* Venice Mallow, *or* Bladder *Ketmia*.

20. KETMIA *veſicaria Africana. Tourn.* African Bladder *Ketmia*.

21. KETMIA *Africana veſicaria, foliis profundius inciſis, vix crenatis. Boerh. Ind.* African Bladder *Ketmia*, with deeply-cut Leaves.

22. KETMIA *Indica, folio haſtato, fructu duro. Tourn.* Indian *Ketmia*, with a Spear-ſhaped Leaf, and a hard Fruit.

23. KETMIA *Ægyptiaca, vitis folio, parvo flore. Tourn.* Egyptian *Ketmia*, with a Vine-Leaf, and a ſmall Flower.

24. KETMIA *Americana aculeata, flore ampliſſimo coccineo. Plum. Cat.* Prickly American *Ketmia*, with a very large ſcarlet Flower.

25. KETMIA *Americana, ampliſſimo folio cordiformi, flore vario. Plum. Cat.* American Ketmia, with a very large heart-ſhaped Leaf, and a variable Flower.

26. KETMIA *Americana fruteſcens, mori folio, flore purpupureo. Plum. Cat.* American ſhrubby Ketmia, with a mulberry Leaf, and a purple Flower.

27. KETMIA *Americana, ampliſſimo folio angulato, fructu hiſpido clypeato. Plum. Cat.* American *Ketmia*, with a large angular Leaf, and a rough Fruit ſhaped like a Shield.

28. KETMIA *Indica, tiliæ folio. Plum. Cat.* Indian *Ketmia*, with a Lime-tree Leaf, *commonly called* the *Mangrove-Tree* in America.

29. KETMIA *Indica, folio anguſto, longiſſimo & crenato, flore phœnicio.* Indian *Ketmia*, with a narrow very long crenated Leaf, and a ſcarlet Flower.

30. KETMIA *Indica humilis, folio diſſecto aſpero, flore parvo candido, inſtar jaſmini Hiſpanici explicato, fundo purpuraſcente. Breyn.* Low Indian *Ketmia*, with a rough cut Leaf, and a ſmall white Flower, which when open, is like the Flower of *Spaniſh* Jaſmine, having a purple Bottom.

31. KETMIA *Indica humilis, folio diſſecto, flore parvo purpureo.* Low Indian *Ketmia*, with a cut Leaf, and a ſmall purple Flower.

The five firſt Sorts are very hardy Shrubs, growing to the Height of ſeven or eight Feet, and may be train'd up to regular Heads: Theſe are very great Ornaments in ſmall Wilderneſs Quarters, when regularly diſpoſed amongſt Plants of the ſame Growth. They produce their Flowers in *Auguſt*; and, if the Autumn proves favourable, their Seeds will be ripe ſoon after *Michaelmas*. Theſe are commonly ſold by the Nurſerymen, with other flowering Shrubs, under the Name of *Althæa frutex*: But by the modern Botaniſts they are removed from that Genus, and call'd by the Name of *Ketmia*, becauſe their Seeds are produced in Veſſels; whereas thoſe of *Althæa* grow in Form of Cheeſes, in the ſame Manner as thoſe of the common *Mallow*.

Theſe Plants are propagated by Seeds, which ſhould be ſown upon a Bed of rich light Earth, in *February* or *March*: And when they come up, they ſhould be conſtantly clear'd from Weeds; and, in dry Weather, often refreſh'd with Water, which will forward their Growth. In theſe Beds they ſhould remain until the ſucceeding Spring; when, in *March*, they muſt be carefully tranſplanted into Beds of the like Soil, at about ten Inches ſquare each Way, obſerving to water them in dry Weather, as alſo to keep them clear from Weeds: In theſe Beds they may continue two Years, by which Time they will ſpread ſo as to meet each other; therefore you muſt, in *March*, remove them either into the Places where they are deſign'd to remain, or into a Nurſery, allowing them three Feet diſtance, Row from Row, and eighteen Inches aſunder in the Rows; being careful, in taking them up, not to break or bruiſe their Roots, which would endanger their growing; and, in dry Weather, give them ſome Water, until they have taken Root; and lay ſome Mulch upon the Surface of the Ground, to prevent its drying too faſt; and be careful to cut down the Weeds between them.

Theſe Plants may alſo be propagated by Layers, or Suckers taken from the Roots of old Trees: But the latter Method is by no means adviſeable; becauſe the Plants raiſed that Way are ſeldom ſo well rooted, and are very ſubject to produce Suckers, whereby the Shrubs are rendered unſightly.

The former Method may be practiſed, in order to preſerve the particular Kinds: But as they are ſo eaſily propagated by Seeds, which generally produce the handſomeſt Plants, and there will be a Chance to obtain different colour'd Flowers that Way, ſo it is generally preferr'd to any other Method. They will alſo take by Inarching, whereby the ſeveral colour'd Flowers may be obtain'd upon one and the ſame Tree; and by this Method, that Sort with variegated Leaves may be increaſed. Theſe Shrubs require very little Culture, but only to clear them from Weeds, and to dig the Ground about them every Spring; and if there are any decayed Branches, they may be at that Time cut out; but they will not require any other Pruning.

The ſixth and ſeventh Sorts are tender, coming from a warmer Country: Theſe may be propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring; and when they are come up, they ſhould be tranſplanted into another moderate Hot-bed, to bring them forward: After which, they muſt be planted into Pots fill'd with freſh light Earth, and plunged into a Hot-bed, to incourage their Rooting; and in *June* they may be expoſed to the open Air, in ſome Place where they may be defended from ſtrong Winds: But they muſt be houſed early in Autumn, when they ſhould be placed in a warm Green-houſe, where they will endure the Winter very well, without any artificial Warmth, tho' indeed they will make but very little Progreſs in this Management, nor will they ever produce Flowers, unleſs they are in they ſucceeding Spring placed into a moderate Bark-bed in the Stove, where they will thrive exceedingly; and if a due Proportion of Air be given to them, that they may not draw up too faſt, they will produce Flowers in the Autumn: But unleſs they have the Aſſiſtance of a Fire, they will ſcarcely ripen their Seeds in *England*.

Theſe Plants were originally brought from *China*, where they are greatly admired, not only for their Beauty, but alſo for an odd Circumſtance in their Flowers, which is, their changing Colour at different Times of the ſame Day; in the Morning they are White, at Noon Red, and in the Evening Purple. Theſe Flowers are in Shape ſomewhat like the *Holihock*, but ſeem to be of ſhort Duration: The Double being much preferable to the Single, the Seeds of that ſhould be conſtantly ſow'd; for amongſt the Plants produced from Seeds of the Double, there will always be Single Flowers produced; as is the Caſe of all double Flowers which produce Seeds. They are known in the *Weſt-Indies*, where they are now in great Plenty, by the Name of *Martinico Roſe*; I ſuppoſe, becauſe the Inhabitants of that Iſland firſt procured the Seeds; and from thence they have ſince been ſpread into moſt of the other Iſlands.

The eighth, ninth, and tenth Sorts are perennial Plants, which die to the Surface every Winter, and riſe again the ſucceeding Spring: They commonly produce their beautiful Flowers late in Autumn, but rarely perfect Seeds in our Climate. They are propagated by Seeds, which are eaſily procured from *Virginia* or *Carolina*, where they are in great Plenty. The Seeds ſhould be ſown in *March*, upon a moderate Hot-bed; and when the Plants come up, they ſhould be removed into ſmall Pots fill'd with light rich Earth, and plunged into another Hot-bed, to bring them forward: And in the Month of *June*, they may be expoſed to the open Air, in a well-ſhelter'd Situation, where they may remain until *October*, when they muſt be removed into Shelter for the Winter Seaſon: during which Time they will require no farther Care than to be protected from ſevere Froſts; ſo that if they are placed into a Hot-bed Frame, where they may be expoſed to the open Air in mild Weather, and only cover'd in Froſts, they will do better than when they are placed into the Green-houſe.

In the Spring they may be turn'd out of the Pots, and planted into the full Ground, under a warm Wall or Pale, where they will thrive much better than in Pots, and will produce their Flowers much larger, and in greater Quantities: tho', if you would obtain Seeds from them, the only Method is, to keep one of each Sort in Pots, which ſhould be plung'd into a very moderate Bark-bed in the Stove, giving them a great Share of Air; in which Place they will flower in *June*, and produce ripe Seeds in Autumn.

The eleventh, twelfth, thirteenth, fourteenth, fifteenth, ſixteenth, ſeventeenth, and eighteenth Sorts are much tenderer than any of the former: Theſe are all propagated by Seeds, which muſt be ſown on a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be each of them tranſplanted into a ſeparate ſmall Pot, fill'd with light freſh Earth, and plung'd on a freſh Hot-bed, where they ſhould be frequently water'd; and in warm Weather, the Glaſſes ſhould be raiſed with Bricks, to admit freſh Air to them, which will prevent their drawing up weak; and when their Roots have fill'd the ſmall Pots, they ſhould be ſhaken out of them, and put into larger, and removed to a third Hot-bed, where they may remain until they are grown up to touch the Glaſſes; obſerving (as was before directed) to give them Water frequently, as alſo a large Share of Air in warm Weather; then you ſhould put them into larger Pots, and remove them into the Stove, where they will produce their Flowers in *July*, and in *Auguſt* their Seeds will ripen: But except they are thus managed, they will rarely produce either Seeds or Flowers in our Climate; tho' they may be kept alive in the Summer, if planted in the full Ground.

Theſe Plants, tho' they may produce Seeds the firſt Year, yet they may be continued two or three Years, if preſerved in a moderate Stove in Winter, and frequently refreſh'd with Water: Yet ſince they are eaſily raiſed from Seeds, and young Plants are much more ſightly than the old ones, it is hardly worth while to fill a Stove with them, ſince there are ſo many other Sorts that will not flower or ſeed the firſt Year, which will take up all the Room there in Winter.

The Flowers of theſe Plants are very beautiful, but are of ſhort Duration, ſeldom continuing longer than one Day; but they are ſucceeded by freſh Flowers, if the Plants are ſtrong and healthy, otherwiſe there is little Pleaſure in them in our Country: But in the *Weſt-Indies*, where they grow in great Plenty, and often ariſe to the Height of a Shrub, they are more productive of Flowers, and are in great Eſteem amongſt the Inhabitants of thoſe Countries.

The thirteenth Sort is by ſome People valued for the exceeding Sweetneſs of its Seeds; as are the fifteenth and ſixteenth Sorts for their Seed-veſſels, the Juice of which the People of *Barbadoes*, *Jamaica*, &c. make uſe of, to add a pleaſant Tartneſs to their Viands. And the Pods of the ſeventeenth and eighteenth Sorts are by them put into their Soups, to thicken them. For all which Purpoſes theſe Plants are much cultivated in thoſe Countries; but with us they are only preſerved as Curioſities.

The nineteenth, twentieth, and twenty-firſt Sorts are annual Plants, which are propagated by ſowing their Seeds in *March*, in the Places where they are deſigned to remain; for they generally form downright Woody Roots, and ſeldom ſucceed well if tranſplanted, except it be done while the Plants are very young: They delight in a freſh light Soil, and an open Situation; for if they are over-ſhaded with Trees, they never thrive well, nor produce ſo great a Number of Flowers.

They are very proper Ornaments for the Borders of Pleaſure-Gardens, where, being intermix'd with other annual Plants, they make an agreeable Variety, and are very hardy, requiring no other Culture than only to ſow their Seeds, and keep them conſtantly clear from Weeds. They produce their Flowers in *June* and *July*, and their Seeds are perfected ſoon after; and tho' their Flowers are of ſhort Duration, ſeldom continuing open above half a Day, (which occaſion'd *Gerard*, in his *Herbal*, to call them *Flowers of an Hour*,) yet they are every Day ſucceeded by freſh Flowers, until the Froſt prevents them.

The laſt ten Sorts of Ketmia are tender Plants, being Natives of the warmeſt Climates; the twenty-ſecond, twenty-third, twenty-fourth, twenty-fifth, twenty-ſixth, twenty-ſeventh, twenty-eighth, and twenty-ninth Sorts, will abide two or three Years, provided they are kept in a warm Stove in Winter, tho' all of them will produce Flowers and good Seeds the firſt Seaſon, (provided they are brought forward early in the Spring) except the twenty-eighth Sort, which grows to the Height of fifteen or ſixteen Feet, ſo ſeldom flowers in its native Country until the ſecond or third Year. The thirtieth and thirty-firſt Sorts are annual Plants, which periſh ſoon after they have perfected their Seeds.

Theſe Plants are propagated by Seeds, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are come up two Inches high, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light rich Earth, and plunged into the Hot-bed again, obſerving to water and ſhade them until they have taken new Root; after which Time they ſhould have a large Share of freſh Air in warm Weather, and muſt be frequently watered. As the Plants advance in their Growth, ſo they ſhould be ſhifted into larger Pots, and brought forward in Hot-beds after the manner directed for *Amaranths*; by which Method they may be brought to flower in *July*, and their Seeds will ripen in *September*.

The twenty-eighth Sort grows naturally in low ſwampy Places in the *Weſt-Indies*, where their Branches bend down to the Earth, and ſend forth Roots, ſo that one ſingle Plant will in few Months have many Trunks, which will ſpread over a large Spot of Ground. The Bark of theſe Trees is wrought into Ropes, and is of great Uſe to the Inhabitants of *America*.

KITCHEN-GARDEN: The *Kitchen-Garden* ſhould always be ſituated on one Side of the Houſe, ſo as not to appear in Sight, but muſt be placed near the Stables, for the Conveniency of Dung, which ought always to be conſider'd in the Diſpoſition of the Buildings, and the laying out of the Garden: for if this Garden be placed at a great Diſtance from the Stables, the Labour will be very great in wheeling the Dung; and ſuch Expences ſhould ever be avoided, if poſſible.

As to the Figure of the Ground, that is of no great Moment, ſince in the Diſtribution of the Quarters all Irregularities may be hid; tho', if you are at full Liberty, an exact Square is preferable to any other Figure.

The great Thing to be conſider'd, is, to make Choice of a good Soil, not too wet, nor over dry, but of a middling Nature; nor ſhould it be too ſtrong or ſtubborn, but of a pliable Nature, and eaſy to work: And if the Place where you intend to make the *Kitchen-Garden* ſhould not be level, but high in one Part, and low in another, I would by no means adviſe the levelling it; for by this Situation you will have an Advantage which could not be obtain'd on a perfect Level, which is, the having one Part of dry Ground, for early Crops, and the low Part for late Crops, whereby the Kitchen may be the better ſupplied throughout the Seaſon with the various Sorts of Herbs, Roots, &c. And in very dry Seaſons, when in the upper Part of the Garden the Crops will greatly ſuffer with Drought, then the lower Part will ſucceed, and ſo *vice verſa*; but I would by no means direct the chuſing a very low moiſt Part of Ground for this Purpoſe; for altho' in ſuch Soils Garden-Herbs are commonly more vigorous and large in the Summer Seaſon, yet they are ſeldom ſo well taſted or wholſome as thoſe which grow upon a moderate Soil: and eſpecially ſince in this Garden your choice Fruits ſhould be planted, ſo it would be wrong to have a very wet Soil.

This Garden ſhould be fully expoſed to the Sun, and by no means over-ſhadow'd with Trees, Buildings, &c. which are very injurious to your Kitchen-Plants and Fruit-Trees; but if it be defended from the North Wind by a diſtant Plantation, it will greatly preſerve your early Crops in the Spring; as alſo from the ſtrong South-Weſt Winds, which are very hurtful in Autumn to Fruit and Garden-Herbs.

The Quantity of Ground neceſſary for a *Kitchen-Garden* muſt be proportion'd to the Largeneſs of the Family, or the Quantity of Herbs deſired: For a ſmall Family, one Acre of Ground may be ſufficient; but for a large Family, there ſhould not be leſs than three or four Acres; becauſe, when the Ground is regularly laid out, and planted with Eſpaliers of Fruit-Trees, as will hereafter be directed, this Quantity will be found little enough, notwithſtanding what ſome Perſons have ſaid on this Head.

This Ground muſt be wall'd round, and if it can be conveniently contrived ſo as to plant both Sides of the Walls, it will be a great Advantage to the Quantity of Wall-Fruit. Theſe Walls ſhould be built about 12 Feet high, which will be a ſufficient Height for any Sort of Fruit. If the Soil where you intend to place your *Kitchen-Garden* be very ſtrong, then you ſhould plow or dig it three or four times before you plant any thing therein; and if you throw it up in Ridges, to receive the Froſt in Winter, it will be of great Service to meliorate and looſen its Parts.

The Manure which is moſt proper for ſuch Soils, is Seacoal Aſhes, and the Cleanſing of Streets or Ditches, which will render it light much ſooner than any other Dung or Manure; and the greater the Quantity of Aſhes, the better, eſpecially if the Ground be cold; and where theſe Aſhes are not to be obtain'd in Plenty, Sea Sand is very proper, or rotten Wood; or the Parts of Vegetables rotted are very good: all which will greatly looſen the Soil, and cauſe it to be not only eaſier to work, but alſo more advantageous for the Growth of Plants.

But, on the contrary, if your Soil be light and warm, you ſhould manure it with rotten Neats-dung, which is much preferable to any other, for hot Soils; but if you uſe Horſe-dung, it muſt be well rotted, otherwiſe it will burn up the Crops, upon the firſt hot dry Weather.

The Soil of this Garden ſhould be at leaſt two Feet deep, (but if deeper, it will be ſtill better) otherwiſe there will not be Depth enough for many Sorts of eſculent Roots, as *Carrots*, *Parſnips*, *Beets*, &c. which run down pretty deep in the

Ground; and moſt other Sorts of eſculent Plants delight in a deep Soil.

You ſhould alſo endeavour to have a Supply of Water in the different Parts of this Garden, which, if poſſible, ſhould be contain'd in large *Baſons* or *Reſervoirs*, where it may be expoſed to the open Air and Sun, that it may be ſoften'd thereby; for ſuch Water as is taken out of Wells, *&c.* juſt as it is uſed, is by no means proper for any Sort of Plants.

In the Diſtribution of this Garden, after having built the Walls, you ſhould lay out Banks or Borders under them, which ſhould be at leaſt ten Feet broad, whereby the Roots of the Fruit-Trees will have greater Liberty than in ſuch Places where the Borders are not above three or four Feet wide; and upon theſe Banks you may ſow many Sorts of early Crops, if expoſed to the South; and upon thoſe expoſed to the North, you may have ſome late Crops: but I would by no means adviſe the planting any Sort of deep-rooting Plants too near the Fruit-Trees; but rather to have ſome Reed Hedges fix'd in ſome of the warmeſt Quarters, under which you ſhould ſow and plant early *Peas*, *Beans*, &c. where they will thrive as well as if planted under a Wall, and hereby your Fruit-Trees will be intirely freed from ſuch troubleſome Plants.

Then you ſhould proceed to dividing the Ground out into Quarters, which muſt be proportion'd to the Largeneſs of the Garden; but, I would adviſe, never to make them too ſmall, whereby your Ground will be loſt in Walks, and the Quarters being incloſed by Eſpaliers of Fruit-Trees, the Plants therein will draw up ſlender, and never arrive to half the Size as they would do in a more open Expoſure.

The Walks of this Garden ſhould be alſo proportion'd to the Size of the Ground, which in a ſmall Garden ſhould be ſix Feet, but in a large one ten; and on each Side of the Walk ſhould be allow'd a Border three or four Feet wide between the Eſpalier and the Walk, whereby the Diſtance between the Eſpaliers will be greater, and the Borders being kept conſtantly work'd and manur'd, will be of great Advantage to the Roots of the Trees; and in theſe Borders may be ſown ſome ſmall Sallet, or any other Herbs, which do not continue long, or root too deep; ſo that the Ground will not be loſt.

But the Walks of theſe Gardens ſhould not be gravell'd; for as there will conſtantly be Occaſion to wheel Manure, Water, *&c.* upon them, ſo they would ſoon be defaced and render'd unſightly; nor ſhould they be laid with Turf; for Green Walks would abſorb the Rays of Light too much, and thereby cauſe the Fruit to be ill-taſted: but, on the contrary, only level the Surface of the Walks; and if you have either Lime-Rubbiſh or Sand juſt to cover over the Tops of them, to render them drier or fitter to walk on than the natural Soil, they will be much preferable to any other Sort of Walks.

The beſt Figure for the Quarters to be diſpoſed into, is a Square or an Oblong, where the Ground is adapted to ſuch a Figure; otherwiſe they may be triangular, or of any other Shape, which will be moſt advantageous to the Ground.

Theſe Quarters ſhould be conſtantly kept clear from Weeds; and when any Part of the Ground is unoccupied, it ſhould always be trench'd up into Ridges, that it may ſweeten, and imbibe the nitrous Particles of the Air, which is of great Advantage to all Sorts of Land, and the Ground will then be ready to lay down, whenever it is wanted.

The Ground in theſe Quarters ſhould not be ſown or planted with the ſame Crop two Years together; but the Crops ſhould be annually changed, whereby they will prove much better than when they conſtantly grow upon the ſame Spot. Indeed the *Kitchen-Gardeners* near *London*, where Land is dear, are often obliged to put the ſame Crop upon the Ground for two or three Years together; but then they dig and manure their Land ſo well every Year, as to render it almoſt new: tho' notwithſtanding all this, it is conſtantly obſerved, that freſh Land always produces the beſt Crops.

In one of theſe Quarters, which is ſituated neareſt to the Stables, and beſt defended from the cold Winds, ſhould be the Place where you raiſe your early *Cucumbers* and *Melons*; for which Purpoſe it will be very proper to ſurround that Part with a Reed-Hedge, which will hide the Beds from Sight, and preſerve them from Winds: The Size of this Place ſhould alſo be proportion'd to the Quantity of Beds intended; but it ſhould be large enough to contain two Years Beds, or elſe you ſhould have two of theſe Places, that you may every Year change them, which will be found of great Advantage to your Plants: but if your Garden be too ſmall to admit of this, then you ſhould always prepare a ſufficient Quantity of freſh Earth for theſe Beds, otherwiſe they will not ſucceed well.

The moſt important Points of general Culture conſiſt in well digging and manuring the Soil, and giving a proper Diſtance to each Plant, according to their different Growths, (which is conſtantly exhibited in their ſeveral Articles in this Book) as alſo to keep them clear from Weeds; for if Weeds are permitted to grow until their Seeds are ripe, they will ſhed upon the Ground, and fill it ſo as not to be gotten out again in ſeveral Years. You ſhould alſo obſerve to keep your Dunghils always clear from Weeds; for it will be to little Purpoſe to keep the Garden clean if this is not obſerved; for the Seeds falling among the Dung, will be brought into the Garden, whereby there will be a conſtant Supply of Weeds yearly introduced, to the no ſmall Damage of your Plants, and a perpetual Labour occaſion'd to extirpate them again. As for all other neceſſary Directions, they will be found in the Articles of the ſeveral Sorts of *Kitchen-Garden* Plants; which renders it needleſs to be repeated in this Place.

KNIGHTS CROSS, or SCARLET CROSS, is the Scarlet Lychnis. *Vide* Lychnis.

L A

LABIATE-FLOWERS, are ſuch as have Lips; or, more properly, a Labiated Flower is an *irregular monopetalous Flower*, divided into two Lips; the upper is call'd the *Creſt*, the under, the *Beard*: Sometimes the *Creſt* is wanting, and then the *Style* and *Chives* ſupply its Place; as in the *Ground-Pine*, *Scordium*, *Bugula*, &c. but the greateſt Part have two *Lips*, which, in ſome Species, the *Upper-Lip* is turn'd upwards, as the *Ground-Ivy*, &c. but moſt uſually the *Upper-Lip* is convex above, and turns the hollow Part down to the *Lower-Lip*, and ſo repreſents a kind of *Helmet* or *Monk's Hood*, from whence theſe are call'd *Galeate*, *Cucullate*, and *Galericulate* Flowers, in which Form are moſt of the *Verticillate Plants*.

LABLAB. *Vide* Phaſeolus.

LABRUM VENERIS. *Vide* Dipſacus.

LABRUSCA. *Vide* Vitis.

LABURNUM. *Vide* Cytiſſus.

LABYRYNTH, [Λαβύρινθος,] a winding, mazy, and intricate turning to and fro thro' a Wilderneſs or a Wood.

The Deſign of a *Labyrinth* is, to cauſe an intricate and difficult Labour to find out the Center; and the Aim is, to make them ſo intricate, that a Perſon may loſe himſelf in it, and meet with as great a Number of Stops and Diſappointments as is poſſible, they being the moſt valuable that are moſt intricate.

As to the Contrivance of them, it will not be poſſible to give Directions in Words; there are ſeveral Plans and Deſigns in Books of Gardening: They are rarely met with but in great and noble Gardens, as *Hampton-Court*, &c.

There are two Ways of making them, the firſt is, with ſingle Hedges: This Method has been practiſed in *England*. Theſe, indeed, may be beſt, where there is but a ſmall Spot of Ground to be allow'd for the making them; but where there is Ground enough, the double are moſt eligible.

Double ones, or thoſe that are made with double Hedges of a conſiderable Thickneſs of Wood between Hedge and Hedge, are approved as much better than ſingle ones, as is the Manner of making them in *France*, and other Places, of all which that of *Verſailles* is allow'd by all to be the nobleſt of its Kind in the World.

It is an Error in *Labyrinths* in making them too narrow, for by that means the Hedges muſt be kept cloſe clipt; whereas, if the Walks be made wider, according to the foreign Practice, they will not ſtand in need of it.

The Walks are made with Gravel, uſually ſet with Hornbeams; the Paliſades ought to be ten, twelve, or fourteen Feet high; the Horn-beam ſhould be kept cut, and the Walks roll'd.

LACRYMA JOBI, [ſo call'd, becauſe the Seed of it reſembles a Tear or Drop.] Job's Tears.

The *Characters* are;

It hath the whole Habit of a Reed; the Male Flowers (which have no Petals) are produced in a Spike on different Parts from the Female of the ſame Plant; the Ovary is a long Tube with two Horns, which becomes a hard ſtrong Fruit, containing one Seed.

The *Species* are;

1. LACHRIMA JOBI. *Cluſ. Hiſt.* Common Job's Tears.
2. LACHRYMA JOBI *latiore folio. Tourn.* Broad-leav'd Job's Tears.
3. LACHRYMA JOBI *Americana altiſſima, arundinis folio & facie. Plum.* Talleſt American Job's Tears, with a Leaf and the Face of Reeds.

The firſt Sort is a Kind of Corn which is often cultivated in *Portugal*, *Italy*, and ſome other warm Countries, where they ſtring the Seeds (which are very ſmooth, and of a bright Aſh Colour) for Beads; and in ſcarce Years of other Grain, I have been inform'd, the poorer Sort of People make Bread of it; but I do not find it is any where cultivated for that Purpoſe: the natural Place of its Growth is in *Candia*, and the other Iſlands of the *Archipelago*.

The ſecond Sort is a Variety of the firſt, from which it differs, in having a much broader Leaf. Theſe are ſeldom cultivated in *England*, unleſs in ſome curious Gardens for the ſake of Variety. Theſe are both annual Plants, which muſt be ſown the Beginning of *March*, on a warm Border of light Earth, at about a Foot aſunder or more, and require no other Care, but to keep them clear from Weeds; and if the Seaſon proves warm, they will perfect their Seeds very well in this Country.

The third Sort grows plentifully in ſeveral Parts of *America*, where the poorer Sort of Inhabitants make a kind of Flour of the Seeds, with which they make Cakes to ſerve them, inſtead of Bread. This Sort has been brought into *Europe*, but the Seeds have not come to Perfection in this Country; for it requires much Warmth, and a long Summer, to ripen it. The Roots of this Kind have remained in the open Air thro' the Winter, and have made freſh Shoots the following Spring; ſo that I believe it is a biennial Plant in its native Country. If this Sort is propagated in *England*, as a Curioſity, the ſureſt Method to bring it to Perfection is, to ſow the Seeds in ſmall Pots, filled with light Earth, and plunge them on a moderate Hot-bed, to bring up the Plants. As ſoon as theſe appear, they ſhould have a large Share of freſh Air admitted to them, to prevent their being drawn up weak; and when the Weather is warm, they ſhould be inured to bear the open Air by degrees, into which the Plants muſt be removed about the middle of *April*; at which Time it will be proper to ſhift them into larger Pots, and place them in a warm Situation, being careful to water them frequently in dry Weather. By this Management the Plants having their Roots confined in the Pots, will not grow ſo large, as thoſe in the full Ground, ſo will ſooner produce Seed. If the Seaſon proves favourable, you may hope to bring it to Perfection: but whenever it fails, the Pots may be removed into the Greenhouſe in Autumn, where the Plants may be preſerved thro' the Winter; and thereby good Seeds may be obtained the following Seaſon.

LACTIFEROUS PLANTS, are ſuch as abound with a milky Juice, as the *Tithymalus*, *Sonchus*, *Lactuca*, &c.

LACTUCA, [ſo call'd from *Lac*, Lat. *Milk*, becauſe the Leaves, Stalks, Flower, and Branch being broken, plentifully emit a Milk, or white milky Juice, quickly turning yellow and bitteriſh] Lettuce.

The *Characters* are;

It hath a fibroſe Root, which, is, for the moſt part, annual: the Leaves are ſmooth, and grow alternately upon the Branches: the Stalks are, for the moſt part, ſlender, and ſtiff, and do commonly terminate into a ſort of Umbel: the Cup of the Flower is oblong, ſlender, and ſcaly: the Seeds are oblong, depreſs'd, and generally terminate in a Point.

It would be beſide my Purpoſe to mention in this Place the ſeveral Sorts of *Lettuce* that are to be found in Botanick Writers, many of which are Plants of no Uſe, and are never cultivated but in Botanick Gardens for Variety, and ſome of them are found wild in many Parts of *England*. I ſhall therefore paſs over thoſe here, and only mention the ſeveral Sorts which are cultivated in the Kitchen-Garden for Uſe: 1. *Common* or *Garden Lettuce.* 2. *Cabbage Lettuce.* 3. *Sileſia Lettuce.* 4. *Dutch Brown Lettuce.* 5. *Aleppo Lettuce.* 6. *Imperial Lettuce.* 7. *Green Capuchin Lettuce.* 8. *Verſailles* or *Upright White Cos Lettuce.* 9. *Black Cos.* 10. *White Cos.* 11. *Red Capuchin Lettuce.* 12. *Roman Lettuce.* 13. *Prince Lettuce.* 14. *Royal Lettuce.*

The firſt of theſe Sorts is commonly ſown very young, for cutting, to mix with other ſmall Sallet Herbs, and is only different from the ſecond Sort, in being a Degeneracy therefrom, or otherwiſe the ſecond is an Improvement by frequent Cultivation from the firſt; for if the Seeds are ſaved from ſuch Plants of the ſecond Sort as did not cabbage cloſely, the Plants produced from that Seed will all degenerate to the firſt Sort, which is by the Gardeners call'd *Laped Lettuce*, to diſtinguiſh it from the other, which they call *Cabbage Lettuce.* The Seeds of the firſt, which are commonly ſaved from any of the Plants, without having regard to their Goodneſs, are generally ſold at a very cheap Rate, (eſpecially in dry Seaſons, when theſe Plants always produce the greateſt Quantity of Seeds) tho' ſometimes this Seed is ſold in the Seed-ſhops, and by Perſons who make a Trade of ſelling Seeds, for the *Cabbage Lettuce*, which is often the Occaſion of People's being diſappointed in their Crop: ſo that this Sort ſhould never be cultivated but to be cut up very young, for which Purpoſe this is the only good Sort, and may be ſown any Time of the Year, obſerving only in hot Weather to ſow it on ſhady Borders, and in the Spring and Autumn upon warm Borders; but in Winter it ſhould be ſown under Glaſſes, otherwiſe it is ſubject to be deſtroy'd by ſevere Froſts.

The *Cabbage Lettuce* may alſo be ſown at different Times of the Year, in order to have a Continuation of it thro' the whole Seaſon; the firſt Crop is generally ſown in *February*, which ſhould be upon an open warm Spot of Ground, and when the Plants are come up, they ſhould be thin'd out, to the Diſtance of ten Inches each Way, which may be done by houghing them out, as is practiſed for *Turnips*, *Carrots*, *Onions*, &c. provided you have no Occaſion for the ſuperfluous Plants, otherwiſe they may be drawn up, and tranſplanted into another Spot of good Ground at the ſame Diſtance, which if done before the Plants are too large, they will ſucceed very well, tho' they will not be ſo large as thoſe which were left upon the Spot where they were ſown; but they will come ſomewhat later, which will be of Service, where People do not continue ſowing every Month.

You muſt alſo obſerve in ſowing the ſucceeding Crops, as the Seaſon advances, to chuſe a ſhady moiſt Situation; but not under the Drip of Trees, otherwiſe, in the Heat of Summer, they will run up to Seed before they cabbage: In the Beginning of *Auguſt*, you ſhould ſow the laſt Crop, which is to ſtand over Winter, and ſhould be ſown thin upon a good light Soil, in a warm Situation, and when the Plants are come up, they muſt be hough'd out, ſo as to ſtand ſingly, and cut down all the Weeds to clear them; and the Beginning of *October* they ſhould be tranſplanted into warm Borders, where, if the Winter is not very ſevere, they will ſtand very well; but in order to be ſure of a Crop, it will be adviſeable to plant a few upon a Bed pretty cloſe, where they may be arched over with Hoops, and in ſevere Froſts they ſhould be covered with Mats and Straw, or Peaſe-haulm, to ſecure them from being deſtroy'd, and in the Spring of the Year they may be tranſplanted out into a warm rich Soil, at the Diſtance beforemention'd; but ſtill thoſe which grew under the Wall, if they eſcaped the Winter, and were ſuffer'd to remain, will cabbage ſooner than thoſe which are removed; but you muſt obſerve not to place them too cloſe to the Wall, which would occaſion their growing up tall, and prevent their being large or hard.

In order to ſave good Seeds of this Kind, you ſhould look over your *Lettuces* when they are in Perfection; and ſuch of them as are very hard, and grow low, ſhould have Sticks thruſt into the Ground, by the ſides of as many of them as you intend for Seed, to mark them from the reſt; and you ſhould carefully pull up all the reſt from amongſt them as ſoon as they begin to run up, if any happen to be left, leſt, by intermixing with the good ones, the Seeds may degenerate.

It may be, ſome Perſons may object, that ſuppoſe ſome bad ones ſhould happen to be left among them, (for Seeds to ſow for ſmall Sallets) yet the good ones being mark'd, the Seeds need not be mix'd, and ſo no Danger can enſue from thence: But notwithſtanding ever ſo much Care being taken to keep the Seeds ſeparate, yet, whether from the intermixing of the *Farina* during the Time of their being in Flower, or what other Cauſe, I can't ſay, but it hath been often obſerved, that where good and bad Plants have ſeeded upon the ſame Spot, the Seeds of the good Plants, which were carefully ſaved ſeparately, have very much degenerated, and proved worſe than ſuch as have ſeeded by themſelves. The Seeds ſhould always be ſaved either from thoſe which ſtood thro' the Winter, or thoſe which were ſown early in the Spring; for the late ones very ſeldom perfect their Seeds.

The *Sileſia*, *Imperial*, *Royal*, *Black*, *White*, and *Upright Cos Lettuces* may be ſown at the following Times: The firſt Seaſon for ſowing theſe Seeds, is at the latter End of *February*, or the Beginning of *March*, upon a warm light Soil, and an open Situation, *i. e.* not overſhadow'd with Trees; and when the Plants are come up, they ſhould be either hough'd out, or tranſplanted into another Spot of Ground, (as was directed for the *Cabbage Lettuce*) obſerving to leave theſe Sorts fifteen or ſixteen Inches apart each Way, which will be full near enough for theſe Plants, eſpecially if the Soil be good; and you muſt carefully keep them clear from Weeds, which is the only Culture they will require, except the *Black Cos Lettuce*, which ſhould be tied up when they are full grown, (in the Manner as was directed for blanching of *Endive*) to whiten their inner Leaves, and render them criſp, otherwiſe they are ſeldom good for much, rarely cabbaging without this Aſſiſtance.

When your *Lettuces* are in Perfection, you ſhould look over them, and mark as many of the beſt of them as you intend for Seed, (in the ſame Manner as was before directed for the common *Cabbage Lettuce*) being very careful not to ſuffer any ordinary ones to ſeed amongſt them, as was before obſerved, which would prove more injurious to theſe Sorts than to the common, as being more inclinable to degenerate with us, if they are not carefully preſerved.

You may alſo continue theſe Sorts thro' the Seaſon, by ſowing of them in *April*, *May*, and *June*, obſerving (as was before directed) to ſow the late Crops in a moiſt ſhady Situation, otherwiſe they will run up to Seed before they grow to any Size; but in *Auguſt*, toward the latter End, you may ſow of theſe ſorts, to abide the Winter, which Plants ſhould be tranſplanted either under Glaſſes, or into a Bed, which ſhould be arch'd over with Hoops, in order to be cover'd in the Winter, otherwiſe in hard Winters they are often deſtroy'd; but you muſt conſtantly let theſe Plants have as much open free Air as poſſible, when the Weather is mild, only covering them in hard Rains or froſty Weather; for if they are kept too cloſely cover'd in Winter, they will be ſubject to a Mouldineſs, which ſoon rots them.

In the Spring theſe Plants ſhould be planted out into a rich light Soil, allowing them at leaſt eighteen Inches diſtance each Way; for if they are planted too cloſe, they are very ſubject to grow tall, but ſeldom cabbage well: and from this Crop, if they ſucceed well, it will be proper to ſave your Seeds; tho' you ſhould alſo ſave from that Crop ſown in the Spring, becauſe ſometimes it happens that the firſt may fail by a wet Seaſon, when the Plants are full in Flower, and the ſecond Crop may ſucceed, by having a more favourable Seaſon; and if they ſhould both ſucceed, there will be no harm in that, ſince the Seeds will grow very well when two Years old, and if well ſaved, at three; but this will not always happen.

The moſt valuable of all the Sorts of *Lettuces* in *England* are the *Verſailles* or *White Cos*, the *Sileſia*, and *Black Cos*; tho' ſome People are very fond of the *Royal* and *Imperial Lettuces*; but they ſeldom ſell ſo well in the *London* Markets as the other, nor are ſo generally eſteem'd.

The *Brown Dutch* and *Green Capuchin Lettuces* are very hardy, and may be ſown at the ſame Seaſons as was directed for the common *Cabbage Lettuce*; and are very proper to plant under a Wall or Hedge to ſtand the Winter, where many times theſe will abide, when moſt of the other Sorts are deſtroy'd; and therefore they will prove very acceptable, at a Time when few other Sorts are to be had; they will alſo endure more Heat and Drought than moſt other Sorts of *Lettuce*, which renders them very proper for late ſowing; for it often happens, in very hot Weather, that the other Sorts of *Lettuce* will run up to Seed in a few Days after they are cabbaged, whereas theſe will abide a Fortnight or three Weeks in good Order, eſpecially if Care be taken to cut the forwardeſt firſt, leaving thoſe that are not ſo hard cabbaged to the laſt. In ſaving of theſe Seeds the ſame Care ſhould be taken to preſerve only ſuch as are very large, and well cabbaged, otherwiſe the Seeds will degenerate, and be good for little.

The *Red Capuchin*, *Roman* and *Prince Lettuces* are pretty Varieties, and are very early Cabbages, for which Reaſon a few of them may be preſerved; as may alſo ſome of the *Aleppo*, for the Beauty of its ſpotted Leaves; tho' very few People care for either of theſe Sorts at Table, when the other more valuable ones are to be obtain'd; but in a Scarcity, theſe may ſupply the Place pretty well. The Seeds of theſe muſt alſo be ſaved from ſuch as cabbage beſt, otherwiſe they will degenerate, and be good for little.

In ſaving Seeds of all theſe Sorts of *Lettuce*, you ſhould obſerve, when the Plants have run up, to fix a Stake down by the Sides of each, to which the Stem ſhould be faſten'd, to prevent their being broke, or blown out of the Ground by Wind, to which the *Sileſia* and the other large-growing *Lettuces* are very ſubject when they are in Flower. You muſt alſo obſerve to cut ſuch Branches of the large growing *Lettuces* as ripen firſt, and not wait to have the Seed of the whole Plant ripe together, which never happens; but on the contrary, ſome Branches will be ripe a Fortnight or three Weeks before others; and when you cut them, they muſt be ſpread upon a coarſe Cloth in a dry Place, that the Seeds may dry; after which, you ſhould beat them out, and dry them again, and then preſerve them for Uſe, being careful to hang them up where Mice and other Vermin can't come at them; for if they do, they will ſoon eat them up.

LACTUCA AGNINI. *Vide* Valerianella.

LADY's SLIPPER. *Vide* Helleborine.

LADY's SMOCK. *Vide* Cardamine.

LAGOPUS. *Vide* Trifolium.

LAMINATED, ſignifies *Plated*. Thoſe Things are ſaid to be *Laminated*, whoſe Contexture diſcovers ſuch a Diſpoſition as that of *Plates* lying over one another.

LAMIUM, [takes its Name of the Fiſh *Lamia*, becauſe it reſembles the frightful Countenance of this Fiſh, when it catches at any Thing. Some call it *Galeopſis*, of Γαλῆ, a *Cat*, becauſe the Flower of it reſembles the Countenance of a Cat when it offers to bite] Archangel *or* Dead-Nettle.

The *Characters* are;

It hath a labiated Flower conſiſting of one Leaf, whoſe upper Lip is hollow like a Spoon; but the under one is divided into two Segments, in the form of a Heart, and both end in Chaps, which are brimmed and edged; out of the Flower-cup, which is fiſtulous, and cut into five Segments, riſes the Pointal, fixed like a Nail in the hinder Part of the Flower; and attended, as it were, by four Embryos, which afterwards become ſo many triangular Seeds, ſhut up in a Huſk, which was before the Flower-cup.

The *Species* are;

1. LAMIUM *purpureum fœtidum, folio ſubrotundo, ſive Galeopſis Dioſcoridis. C. B. P.* Purple ſtinking Archangel or Dead-Nettle.

2. LAMIUM *purpureum fœtidum, folio ſubrotundo, minus. H. L.* Leſſer purple ſtinking Dead-Nettle.

3. LAMIUM *folio oblongo, flore rubro. Park. Theat.* Archangel with an oblong Leaf, and a red Flower.

4. LAMIUM *album, non fœtens, folio oblongo. C. B. P.* White Archangel or Dead-Nettle.

5. LAMIUM *parietariæ facie. Moriſſ. H. R. Bleſ.* Dead-Nettle, with the Face of Pellitory.

6. LAMIUM *folio caulem ambiente, minus. C. B. P.* Leſſer Dead-Nettle, with the Leaves encompaſſing the Stalk.

7. LAMIUM *rubrum minus, foliis profunde inciſis. Raii Syn.* Leſſer red Dead-Nettle, whoſe Leaves are deeply cut.

8. LAMIUM *album fœtidum, folio ſubrotundo, minus. C. B. P.* Leſſer ſtinking Dead-Nettle, with white Flowers and a roundiſh Leaf.

9. LAMIUM *foliis caulem ambientibus, majus. C. B. P.* Greater Dead-Nettle, with the Leaves encompaſſing the Stalk.

10. LAMIUM *orientale, nunc moſchatum, nunc fœtidum, magno flore. Tourn. Cor.* Eaſtern Dead-Nettle, ſometimes ſweet-ſcented, and ſometimes ſtinking, with a large Flower.

11. LAMIUM *orientale, foliis eleganter laciniatis. Tourn. Cor.* Eaſtern Dead-Nettle, with elegantly jagged Leaves.

12. LAMIUM *orientale incanum, flore albo, cum labio ſuperiori crenato. Tourn. Cor.* Hoary Eaſtern Dead-Nettle, with a white Flower, whoſe upper Lip is notched.

13. LAMIUM *orientale incanum, flore purpuraſcente, cum labio ſuperiori crenato. Tourn. Cor.* Hoary Eaſtern Dead-Nettle, with a purpliſh Flower, whoſe upper Lip is notched.

14. LAMIUM *orientale album latifolium altiſſimum. Tourn. Cor.* Talleſt Eaſtern Dead-Nettle, with a broad Leaf, and a white Flower.

The firſt, ſecond, ſixth, ſeventh, eighth, and ninth Sorts, are annual Plants, which grow wild on dry Banks in ſeveral Parts of *England*; ſo are rarely preſerved but in botanick

Gardens, for the ſake of Variety. All theſe Sorts flower in *March* and *April*, and their Seeds are ripe ſoon after, which if permitted to ſcatter, the Plants will come up in great Plenty, and become troubleſome Weeds. The firſt Sort is uſed in Medicine; but the Markets are ſupplied with it from the Fields.

The fourth Sort is alſo very common under Hedges, in divers Parts of *England*; this is alſo uſed in Medicine. The Roots of this Sort ſpread very far under Ground; ſo where it once fixes, it is very difficult to eradicate, eſpecially under Hedges or Trees, where the Roots of this Plant will intermix with thoſe of the Plants, ſo that they cannot be eaſily taken out, without diſturbing the Roots of the Plants. The third Sort is a Variety of the fourth, from which it differs in the Colour of the Flowers, which in this are of a bright red Colour. Theſe two are abiding Plants, which propagate themſelves very faſt by their creeping Roots.

The fifth, tenth, and eleventh Sorts, are annual Plants, which do not grow wild in *England*, but are equally hardy with thoſe before-mentioned. Theſe flower early in the Spring, and if their Seeds are permitted to ſcatter, the Plants will come up in the Autumn in great Plenty. The fifth Sort has no great Beauty, ſo is only preſerved for Variety, being very like our common Dead-Nettle, except in the Difference of the Leaf. But the tenth Sort deſerves a Place in ſome abject Part of the Garden, for the Beauty of its Leaves in Winter, which are variegated ſomewhat like the common *Cyclamen*, and make an Appearance very like that Plant in Winter. Theſe Leaves, in dry Weather, have a muſky Scent on their being gently rubbed; but if they are bruiſed, they become ſtinking and diſagreeable.

The twelfth, thirteenth, and fourteenth Sorts, are abiding Plants, which will trail on the Ground, and ſend forth Roots from the Joints of their Stalks, whereby they propagate themſelves very faſt; ſo where-ever they are permitted to have Room in a Garden, they ſhould be kept within Compaſs; otherwiſe they will ſpread, and become troubleſome.

LAMPSANA, [ſo call'd of Δαπάζω, to *evacuate*; becauſe this Plant being eaten, it purges the Belly. It is alſo call'd *Herba Papillaris*, becauſe it is very good for Chaps in Womens Nipples] Nipple-wort.

The *Characters* are;

It hath a ſemifloſculous Flower, conſiſting of many half Florets, upon which the Embryos ſit, and are included with them in a multifid Cup, conſiſting of one Leaf, which afterward becomes a ſtreaked Veſſel including many narrow-pointed Seeds.

The *Species* are;

1. Lampsana. *Dod. Pempt.* Common Nipplewort.
2. Lampsana *folio ampliſſimo criſpo. Petiver.* Nipplewort with a large curled Leaf.
3. Lampsana *orientalis elatior, foliis nigris maculis aſperſis. D. Sherard.* Taller Eaſtern Nipplewort, with Leaves ſpotted with black Marks.

The firſt Sort is a very common Weed on dry Banks, and on the Way-ſides, in moſt Parts of *England*; the other two Sorts were brought from abroad into the botanick Gardens, where they are preſerved for Variety, but they are not allowed a Place in any other Gardens.

Theſe are all annual Plants, which flower in *April*, and their Seeds ripen in *June*, which if permitted to ſcatter, will ſtock the Ground with Plants; ſo that where they are admitted, there ſhould be but few of the Plants ſuffered to ſeed, and thoſe ſhould be in ſome rude abject Part of the Garden, leſt by their ſcattering Seeds, they ſhould fill the Garden, and over-bear ſuch Plants, as better deſerve a Place.

But where the common Sort hath been ſuffered to ſhed its Seeds, and thereby become a troubleſome Weed, it may be deſtroyed by keeping it houghed down before it comes to flower, ſo that no Plants be permitted to ſcatter Seeds; for as it is an annual Plant, ſo where-ever Care is taken to prevent its Seeding, it will in two or three Years be abſolutely deſtroyed.

The firſt Sort was formerly uſed in Medicine in *England*, and is ſtill continued in Uſe in other Countries: But it is not mentioned by the College of Phyſicians in their Diſpenſatory.

LAND. Its Improvement.

1. By *Incloſing*.

Incloſing of Lands, and dividing the ſame into ſeveral Fields, for Paſture or Tillage, is one of the moſt principal Ways of Improvement, firſt, by aſcertaining to every Man his juſt Property, and thereby preventing an Infinity of Treſpaſſes and Injuries, that Lands in common are ſubject unto; and, ſecondly, it being of itſelf a very great Improvement; for where Land is properly incloſed, and the Hedge-rows planted with Timber-trees, *&c.* it preſerves the Land warm, and defends and ſhelters it from the violent cold nipping Winds, which in ſevere Winters frequently deſtroy much of the Corn, Pulſe, or whatſoever grows on the open Field or champain Grounds. And where it is laid down for Paſture, it yields much more Graſs than the open Fields, and the Graſs will begin to grow much ſooner in the Spring. The Hedges and Trees alſo afford Shelter for the Cattle, from the cold Winds in Winter, as alſo Shade for them in the great Heats of Summer. And theſe Hedges afford the diligent Huſbandman Plenty of Fuel, as alſo *Plough-boot*, *Cart-boot*, &c. And where they are carefully planted and preſerved, furniſh him with Timber, and Maſt for his Swine: Or where the Hedge-rows are planted with Fruit-trees, there will be a Supply of Fruit for *Cyder*, *Perry*, &c. which in moſt Parts of *England*, are of no ſmall Advantage to the Huſbandman.

By this Method of Incloſing, there is alſo much more Employment for the Poor, and is therefore a good Remedy againſt Beggary; for in thoſe open Countries, where there are great *Downs*, *Commons*, *Heaths*, and *Waſtes*, there is nothing but Poverty and Idleneſs to be ſeen amongſt the Generality of their Inhabitants. It is very obſervable of late Years, how much Advantage the Incloſing of the Land in *Worceſterſhire*, and ſome other Counties at a Diſtance from *London*, has been to the Inhabitants; for before this Method was introduced amongſt them, the Lands for the moſt Part lay in Commons, *&c.* upon which the poorer Sort of People built themſelves Cottages with Mud Walls, where they contented themſelves with a Cow or two, and ſome Swine: and thoſe of them who were more induſtrious than the reſt, travelled to the Neighbourhood of *London* every Spring, where they were employed in the Gardens and Fields for the Summer Seaſon, and in Autumn they returned to their native Countries, where they lived in Winter, upon what Money they had ſaved in Summer. But ſince they have converted their Waſtes and Commons into Incloſures, there are but few of the Inhabitants of thoſe Countries, who come to *London* for Work, in compariſon to the Numbers that formerly came; ſo that moſt of the Labourers, who come to *London* for Employment, are either *Welſh*, or Inhabitants of ſome diſtant Counties, where this Improvement hath not as yet been introduced.

The Advantages of incloſing Land are now ſo generally known, that there is no Occaſion for me to enumerate them here; ſince the Improvements which have been made of late Years, in ſeveral Parts of *England*, and the Increaſe of Rent, that is every-where made by thoſe who incloſe, are ſufficient Arguments, to enforce the Practice, and render it general; more eſpecially in the North, where it is moſt neglected; becauſe it would greatly ſhelter the Lands, and render them much warmer than they now are.

In incloſing of Land, there ſhould be regard had to the Nature of the Soil, and what it is intended for; becauſe Corn-Land ſhould not be divided into ſmall Parcels; for beſides the Loſs of Ground in Hedges, *&c.* the Corn doth ſeldom thrive ſo well in ſmall Incloſures, as in more open Fields; eſpecially where the Trees are large in the Hedge-rows. The Graſs alſo in Paſtures is not ſo ſweet near Hedges, or under the Drip of Trees, as in an open Expoſure; ſo that where the Incloſures are made too ſmall, or the Land over-planted with Trees, the Herbage will not be near ſo good, nor in ſo great Plenty, as in larger Fields. Therefore, before a Perſon begins to incloſe, he ſhould well conſider how he may do it to the greateſt Advantage: As for Inſtance, it is always neceſſary to have ſome ſmaller Incloſures near the Habitation, for the Shelter of Cattle, and the Conveniency of ſhifting them from one Field to another, as the Seaſon of the Year may require; and hereby the Habitation, Barns, Stables, and Out-houſes, will be better defended from ſtrong Winds, which often do great Damage to thoſe that are expoſed to their Fury. Theſe ſmall Incloſures may be of ſeveral Dimenſions; ſome of them three, four, ſix or eight Acres in Extent; but the larger Diviſions for Corn ſhould not contain leſs than twenty or thirty Acres, or more, according to the Size of the Farm.

The uſual Method of Incloſing Land, is with a Ditch and Bank ſet with *Quick*. But in Marſh Land, where there is plenty of Water, they content themſelves with only a Ditch, by the Sides of which they uſually plant *Sallows* or *Poplars*, which being quick of Growth, in a few Years afford Shade to the Cattle; and when they are lopped, produce a conſiderable Profit to their Owners. In ſome Counties, the Diviſion of their Lands is by dry Walls, made of flat Stones, laid regularly one upon another, and laying the Top Courſe of Stones in Clay, to keep them together, the Weight of which ſecures the under ones. But in ſome Parts of *Suſſex* and *Hampſhire* they often lay the Foundation of their Banks with flat Stones, which is of a conſiderable Breadth at Bottom: Upon which they raiſe the Bank of Earth, and plant the Hedge on the Top, which in a few Years makes a ſtrong durable Fence, eſpecially if they are planted with *Holly*, as ſome of thoſe in *Suſſex* are.

In Marſhes and open Paſtures, where there are no Hedges, the Ditches are generally made ſix Feet wide at the Top, eſpecially thoſe which are on the Side of high Ways or Commons; but the common Ditches about Incloſures, are ſeldom more than three Feet and a half wide at Top, and one Foot and a half at Bottom, and two Feet deep; that the Sides may have a good Slope, and not be too upright, as they are frequently made about *London*, ſo that they are continually waſhing down with great Rains. In theſe narrow-bottomed Ditches, the Cattle cannot ſtand to turn themſelves, ſo as to crop the *Quick*. But where the Ditches are made wider, they ſhould be proportionally deeper: As for inſtance, if the Ditch is made five Feet broad, it muſt be three Feet deep; and if ſix Feet broad, three and a half Feet deep, and ſo in proportion.

The Method of Incloſing Lands, by raiſing high Banks of Earth, on the Side of which the *Quick* is planted, (as it is too much practiſed in many Places near *London*) is intolerable; for it is not only unſightly, but very expenſive: for theſe Banks are continually waſhing down, ſo that they muſt be repaired every Year at leaſt, if not oftner; otherwiſe the Earth will be in few Years waſhed from the Roots of the *Quick*, that for want of proper Nouriſhment, the Hedge will ſoon decay: which is the Caſe with the greateſt Number of the Hedges about *London*. Beſide, it is a very uncertain Way of planting *Quick* on the Side of a ſteep Bank, where all the Moiſture runs off; ſo that, if the Spring ſhould prove dry, after it is planted, there is a great Hazard whether half the Plants will grow; and thoſe that take, ſeldom make much Progreſs; whereas thoſe planted on the plain Surface, where they enjoy the Advantages of Sun and Moiſture, will in four Years make a better Fence, than one of theſe Bank Hedges will in eight Years, and will continue good much longer than the other. Therefore I ſhould adviſe the Banks on which the Hedges are to be planted, not to be raiſed more than one Foot above the Surface of the Ground, where the Land is dry, and in wet Land not more than two Feet, which will be enough.

I ſhall now mention the moſt proper Plants for making of Fences for the different Soils and Situations, ſo as to anſwer the Expectation of the Planter: And firſt, the *white Thorn* is eſteemed the beſt for Fencing, and will grow upon almoſt any Soil, and in any Situation; but it ſucceeds beſt on a hazle Loam. Of this there are three or four Varieties, which differ in the Breadth of their Leaves, and the Size of their Haws; but that Sort with the ſmalleſt Leaves and Haws, will make the cloſeſt Fence. For it is very certain, that the Branches of all Sorts of Trees, are produced at a Diſtance in proportion to the Size of their Leaves; ſo that *Yews*, and other Ever-green Trees, with ſmall Leaves will always make a cloſer Hedge, than other Trees, whoſe Leaves are larger. Therefore for the cloſeſt Hedge, the ſmalleſt Haws ſhould be choſen; but where the moſt vigorous Shooters are required, for the Advantage of Lopping, there the largeſt Haws ſhould be preferred. But as theſe Hedges are uſually planted from a Nurſery, where the Haws are promiſcuouſly ſown, ſo it is very common to ſee two or three Sorts, planted in the ſame Hedge, which may be eaſily diſtinguiſhed, when they have obtained Strength, by the Difference of their Growth. Indeed, where a Perſon is curious in raiſing of his own *Quick*, it is worth while, to gather the Haws ſeparately, and ſow them apart, and each Sort ſhould be planted in a ſeparate Hedge, which will render the Hedges more equal in their Growth. If theſe Haws are ſown in the Places where they are deſigned to remain for a Fence, they will make a much greater Progreſs in a few Years, than thoſe which are tranſplanted; but as the Seeds remain a whole Year in the Ground, before the Plants appear, ſo few People care to practiſe this Method.

The next to the *white Thorn*, is the *black Thorn*, which tho' not ſo generally eſteemed as the white, yet it will make an excellent Fence, where proper Care is taken in the Planting and After-management of it; and the Loppings of this Hedge make much the beſt Buſhes, and are of longer Duration for Dead-hedges, than any other Sort; and are very proper to mend Gaps in Fences; for their Branches being beſet with ſharp long Thorns, the Cattle are not ſo apt to crop them as the white Thorn, and ſome other Sorts. Theſe Hedges are alſo better, if the Stones are ſown on the Spot where they are to remain, than where the Plants are taken from a Nurſery.

The *Crab* will alſo make a ſtrong durable Fence; this may be raiſed by ſowing of the Kernels in the Place where the Hedge is deſigned; but then there ſhould be great Care taken of the Plants while they are young, to keep them clear from Weeds, as alſo to guard them from Cattle. When theſe Stocks have obtained Strength, ſome of them may be grafted with Apples for Cyder, where the Fence is not expoſed to a publick Road: but theſe Grafts ſhould not be nearer than thirty-five or forty Feet, leſt they ſpoil the Hedge, by their Heads overgrowing and dripping on it.

The *Holly* is alſo an excellent Plant for Ever-green Hedges, and would claim the Preference to either of the former, were it not for the Slowneſs of its Growth while young, and the Difficulty of tranſplanting of the Plants, when grown to a moderate Size. This will grow beſt on cold ſtony Lands, where if it once takes well, the Hedge may be rendered ſo cloſe and thick, as to keep out all Sorts of Animals, and will grow to a great Height, and is of long Duration. Theſe Hedges may be raiſed by ſowing of the Berries, in the Place where they are deſigned to remain: But as they remain in the Ground an intire Year, before the Plants appear, ſo few Perſons care to wait ſo long; therefore the uſual Method is to plant the Hedges with Plants of three or four Years Growth; but where this is practiſed, they ſhould not be tranſplanted till toward the End of *March*; and the Surface of the Ground ſhould be covered with Mulch, near their Roots, after they are planted, to keep the Earth moiſt; and if the Seaſon ſhould prove dry, the Plants ſhould be watered at leaſt once a Week, until they have taken Root, otherwiſe they will be in Danger of miſcarrying.

The *Alder* will alſo make a good Hedge, when planted on a moiſt Soil, or on the Side of Rivers or large Ditches; and will preſerve the Bank from being waſhed away, where there are running Streams; for they ſpread pretty much at Bottom, and ſend forth Suckers from their Roots in great Plenty. But theſe Hedges ſhould be ſhear'd at leaſt once a Year, in order to make them thick. Theſe Alder-hedges are very ornamental, when they are well kept, in large Gardens; and as they will thrive beſt on wet ſwampy Lands, where many other Plants will not live, ſo they ſhould be ſelected for ſuch Situations.

Of late Years the *Furze* has been much propagated for Hedges in ſeveral Parts of *England*, and indeed will make a good Fence on poor ſandy or gravelly Soils, where few other Plants will grow. The beſt Method of raiſing theſe Hedges is, to ſow the Seed about the latter End of *March*, or the Beginning of *April*, in the Place where the Hedge is deſigned; for the Plants will not bear to be tranſplanted, unleſs it be done while they are young, and then there is great Hazard of their Taking. The Ground where the Seeds are to be ſown, ſhould be well cleanſed of Weeds, and the Surface made light; then there ſhould be two or three Drills made (according to the Width which the Hedge is intended) about half an Inch deep, into which the Seeds ſhould be ſcattered pretty thick; and then the Drills ſhould be filled up with the Head of a Rake, to cover the Seeds. This Work ſhould be performed in dry Weather; for if much Wet falls ſoon after the Seeds are ſown, it is apt to burſt them. When the Plants are come up, they ſhould be kept clear from Weeds, that the Plants may ſpread, and grow thick at Bottom; and if theſe Hedges are ſecured from Cattle browzing on them, and are cut every Spring, juſt before they begin to ſhoot, they will make an exceeding cloſe Fence: but where they are deſigned to be cut for Fuel, then the beſt Way is to let them ſpread in Width; and when they are two Years old, to cut them down in the Spring, juſt before they begin to ſhoot, within two or three Inches of the Ground, which will cauſe them to ſend forth a Number of Shoots from each Root, and thereby increaſe the Width of the Hedge; and by ſo doing the Plants will not run up tall and weak, and be in Danger of being weighed down by great Falls of Snow. Theſe Hedges, when they are well grown, may be cut down every third or fourth Year for Fuel, ſo if there is a treble Row of Furze ſown, at about three Feet apart, they may be cut down alternately, ſo that there will be a Fence always remaining. But this is only recommended for ſuch ſandy Lands as let for a ſmall Rent, and where Fuel is ſcarce. The beſt Sort of *Furze* for this Purpoſe is the greater Kind, commonly called the *French Furze*, which will grow to a great Height, and doth not ſpread ſo much as the ordinary ſmall Sort.

Elder is ſometimes planted for Hedges, being very quick of Growth; ſo that if Sticks or Truncheons, about four or five Feet long, be thruſt into a Bank ſlope-wiſe each Way, ſo as to croſs each other, and thereby form a ſort of Chequer-work, it will make a Fence for Shelter in one Year. But as this is a vigorous growing Plant, ſo it will never form a cloſe Fence; and the young Shoots, being very ſoft and pithy, are ſoon broken by Cattle, or unlucky Boys. Beſides, where they are ſuffered to bear Berries, and theſe are ſcattered over the neighbouring Land, they will come up the following Spring, and become very troubleſome. Where theſe Hedges are planted, they may be cut down every third Year, near the Ground; and theſe Stakes (when diveſted of their Bark, ſo as to prevent their Growing) will laſt longer in the Ground, to ſupport Vines, or any other Plants, which do not require tall Stakes, than any other Sort of Tree yet known. And where the Trees are ſuffered to grow to any conſiderable Size, the Wood is as hard as Box; ſo is very uſeful for Turners and Inſtrument-makers. The beſt Seaſon for planting of theſe Truncheons is ſoon after *Michaelmas*, becauſe theſe Plants ſhoot very early in the Spring. Of late Years, there have been many Hedges, and other Plantations, made of the white-berried *Elder*, for the ſake of their Fruit to make Wine; which if rightly made, hath the Flavour of *Frontiniac* Wine, and is by ſome Perſons vended for it.

There are ſome other Plants, which have been recommended for Fences; but thoſe here enumerated are the only uſeful Sorts for ſuch Purpoſes; ſo I ſhall paſs over the others, as not worthy of the Care of the Huſbandman. And as to the farther Direction for Planting, and preſerving of Hedges, with Inſtructions for plaſhing or laying them, the Reader is deſired to turn to the Articles of *Fences* and *Hedges*, where there are particular Directions for theſe Works exhibited; ſo I ſhall not repeat them here.

The Draining of Land, is alſo another great Improvement to it; for tho' Meadows and Paſtures, which are capable of being overflowed, produce a greater Quantity of Herbage than dry Land; yet where the Wet lies too long upon the Ground, the Graſs will be ſour, and extremely coarſe. And where there is not Care taken in Time to drain this Land, it will produce little Graſs, and ſoon be over-run with Ruſhes and Flags, ſo as to be of little Value. The Land which is moſt liable to this, is cold ſtiff Clays, where the Water cannot penetrate, but is contained as in a Diſh; ſo that the Wet which it receives in Winter, continues till the Heat of the Sun exhales the greateſt Part of it.

The beſt Method for Draining of theſe Lands, is, to cut ſeveral Drains acroſs the Land, in thoſe Places where the Water is ſubject to lodge; and from theſe croſs Drains to make a convenient Number of other Drains, to carry off the Water to either Ponds or Rivers, in the lower Parts of the Land. Theſe Drains need not be made very large, unleſs the Ground be very low, and ſo ſituated as not to be near any River, to which the Water may be conveyed: in which Caſe there ſhould be large Ditches dug at proper Diſtances, to contain the Water; and the Earth which comes out of the Ditches, ſhould be equally ſpread on the Land, to raiſe the Surface. But where the Water can be conveniently carried off, the beſt Method is to make under-ground Drains, at proper Diſtances, which may empty themſelves into large Ditches, which are deſigned to carry off the Water. Theſe ſort of Drains are the moſt convenient, and as they are hid from the Sight, do not incommode the Land, nor is there any Ground loſt, where theſe are made.

The uſual Method of making theſe Drains, is to dig Trenches, and fill their Bottoms with Stones, Bricks, Ruſhes or Buſhes, which are covered over with the Earth, which was dug out of the Trenches: but this is not the beſt Method, becauſe the Water has not a free Paſſage thro' the Drains, ſo that whenever there is a Flood, theſe Drains are often ſtopp'd by the Soil which the Water frequently brings down with it. The beſt Method I have yet obſerved to make theſe Drains, is, to dig Trenches to a proper Depth for carrying off the Water, which ſhould be three Feet wide at their Tops, and ſloped down to about a Foot wide at their Bottom; then having prepared a Quantity of good Bruſhwood, the larger Sticks ſhould be cut out to Pieces of about ſixteen or eighteen Inches in Length, which ſhould be laid acroſs the lower Part of the Drain, at about fourteen Inches Diſtance, ſo as to leave about a Foot of the lower Part of the Drain open, thro' which the Water is to paſs; then cover theſe Sticks with the ſmaller Bruſh-wood, Furze, Broom, or any other Kind of Bruſh, laying it lengthwiſe pretty cloſe; on the Top of theſe may be laid Ruſhes, Flags, *&c.* and then the Earth laid on to cover the Whole. Theſe ſort of Drains will continue good for a great Number of Years, and are never liable to the Inconveniencies of the other Drains; for the Water will find an eaſy Paſſage thro' them, and where there is Plenty of Bruſh-wood, they are made at an eaſy Expence; but in ſuch Places where Wood is ſcarce, it would be chargeable to make them. However in this Caſe it would be a great Advantage to theſe Lands, to plant a ſufficient Number of Cuttings of Willow, or the Black Poplar, on ſome of the moiſt Places, which would furniſh Bruſh-wood for theſe Purpoſes in four or five Years; and as the Expence of planting theſe Cuttings is trifling, ſo there cannot be a greater Advantage to an Eſtate which wants Draining, than to practiſe this Method, which is in every Perſon's Power, ſince there is little Expence attending of it.

The beſt Time of the Year for making of theſe Drains, is about *Michaelmas*, before the heavy Rains of Autumn fall; becauſe at this Seaſon, the Land is uſually dry, ſo that the Drains may be dug to a proper Depth. For when the Ground is wet, it will be very difficult to dig to any Depth, becauſe the Water will drain in, where-ever there is an Opening in the Ground.

When theſe Drains are made, and the Water carried off the Land, it will be proper to pare off all the Ruſhes, Flags, *&c.* Which may be laid in Heaps in proper Places to rot, and will afford a good Manure for the Land. The Ground muſt alſo be ploughed, to deſtroy the Roots of noxious Weeds; and if it be laid fallow for one Seaſon, and ploughed two or three times, it will greatly mend the Land. The Ruſhes and Flags, which were pared off the Ground, when rotten, ſhould be ſpread over the Surface, and the Graſs-ſeed ſown thereon, which will greatly forward the Graſs, ſo that it may ſoon be brought to a good Turf; which Land thus mended, has been let for four times the Rent, it was ſet at before.

There are ſome Perſons, who, after they have pared off the Flags, Ruſhes, *&c.* from their Land, lay them in ſmall Heaps, and burn them in dry Weather, then ſpread the Aſhes on the Land to improve it; which is a good Method, where a Perſon is in Haſte to have Graſs again: but where the Ground can be fallowed one Year, it will looſen the Soil, and more effectually deſtroy the Roots of all noxious Weeds; and the Ruſhes, *&c.* when rotted, will afford a much larger Quantity of Manure for the Land, than when it is burnt: beſides this can only be practiſed in the Summer Seaſon, when the Weather is very dry; for if there ſhould fall much Rain, the Fires will go out, and it will be impracticable to burn it. But where the Method of Burning is practiſed, the Heaps ſhould not be too great, and it ſhould burn very ſlowly; which will render the Aſhes a much better Manure, than where the Fire is too violent, or the Heaps too large; for in this Caſe, the Inner-part will be over-burnt, before the Fire reaches the Outſide of the Heap.

As the Draining of cold wet Lands is a great Improvement to them, ſo the Floating or Watering of dry looſe Lands is not a leſs Advantage to them. This may be effected eaſily, where there are Rivers, or Reſervoirs of Water, which are ſituated above the Level of the Ground deſigned to be floated, by under-ground Drains, (made after the Manner of thoſe before directed for Draining of Land) thro' which the Water may be conveyed at proper Seaſons, and let out on the Ground; in order to this, there muſt be good Sluices made at the Heads of the Drains, ſo that the Water may never get out, but at ſuch Times as it is required; for if this be not taken care of, the Water, inſtead of improving the Land, will greatly damage it.

But where the Land lies ſo high, as that there is no Water in the Neighbourhood lying above its Level, it will be more expenſive, becauſe in ſuch Caſe the Water muſt be raiſed by Machines, from Reſervoirs or Streams which lie below it. The moſt common Engine uſed for this Purpoſe, is the *Perſian* Wheel (which being well deſcribed, and figured in *Woolridge's* Art of Huſbandry, is needleſs for me to repeat here). Yet notwithſtanding the Expence of raiſing the Water, it has been found greatly advantageous in many Parts of *England*, to drown the Lands; for the Profit has many times more than doubled the Charge.

The Times for drowning of Land are after the Graſs is cloſe fed, from the Middle or latter End of *November*, till the End of *April*; but it is done to moſt Advantage in the Spring, eſpecially if the Seaſon proves dry. Where the Land is very hot and dry, and it lieth convenient to be watered at a ſmall Expence; it ſhould be repeated every Week in dry hot Weather, which will prove a great Advantage to the Land. But whenever this is done, there ſhould no Cattle be admitted while it is wet; for they will poach, and ſpoil the Turf.

Another great Improvement of Land is by Burning of it, which for ſour, heathy, and *Ruſhy-Land*, be it either hot or cold, wet or dry, is a very great Improvement; ſo that ſuch Lands will in two or three Years after Burning, yield more, excluſive of the Charges, than the Inheritance was worth before. But this is not to be practiſed on rich fertile Land; for as the Fire deſtroys the acid Juice, which occaſions Sterility in the poor Land, ſo it alſo will conſume the good Juices of the richer Land, and thereby impoveriſh it; ſo that it hath been with great Reaſon diſuſed in deep rich Countries.

The uſual Method of Burning Land, is to pare off the Turf with a Breaſt Plough, turning it over as it is cut, that it may dry the better. And if it prove hot dry Weather, when this Work is done, then it needs no more Turning; but if Rain ſhould fall, it muſt be turned, and the Turfs ſet a little hollow, that they may dry the better; and when they are thorough-dry, they may be laid on ſmall Heaps, about half a Cart-load on a Heap, or leſs; for the ſmaller the Heaps are, provided there is Quantity enough to make a good Fire, ſo as to conſume the Whole to Aſhes, it is the better: if the Turf be full of fibroſe Roots, or hath much Moſs or Fern on it, it will burn without any additional Fuel; but if it hath not, the Heaps ſhould be raiſed on ſmall Bundles of Heath, Fern, Gorze, *&c.* which will ſet the Whole on Fire; but there ſhould be no more of theſe Things applied, than what is neceſſary to kindle the Fire, becauſe the ſlower the Turf conſumes, the better will be the Aſhes. When the Turf is wholly conſumed, the Aſhes ſhould be equally ſcattered over the Ground in a calm Day, leſt the Wind ſhould drive it in Heaps. Then the Land ſhould be gently ploughed, and the Seeds ſown thereon; for if the Ground is plough'd too deep, the Aſhes will be buried too low for the Roots of the Graſs or Corn to reach them, for a conſiderable Time; nor ſhould the Aſhes lie too near the Surface, becauſe then the Roots will reach them too ſoon, and the Strength of the Aſhes will be ſpent to nouriſh only the Blade; ſo that the Corn will grow too rank in Winter, and when the Roots in the Spring ſtrike down lower, they will meet with a poorer Soil, ſo that the Stalks and Ears will not have ſo much Advantage from the Improvement, as the uſeleſs Blade. But where Care is taken in this Particular, it is wonderful what Succeſs it hath: for by this Method, the pooreſt Plains, and ſour heathy Lands, have been rendered as fertile, as almoſt any good cultivated Ground whatever.

It is alſo a very great Improvement, where Land is overgrown with *Broom*, *Furze*, &c. to ſtub them up by their Roots; and when they are dry, lay them on Heaps, and cover them with the Parings of the Earth, and burn them, and ſpread the Aſhes over the Ground. By this Method vaſt Tracts of Land, which at preſent produce little or nothing to their Owners, might be made good for a ſmall Expence, ſo as to become good Eſtates to the Proprietors.

The ſeveral other Improvements of Land by Dunging, will be exhibited under the Article *Manure*. And as to the Improvement of Land, by ſowing of Graſſes, *&c.* that is mentioned under the ſeveral Articles, where the Plants are treated of; as the different Kinds of *Clover* or *Trefoil* under *Trifolium*, the *St. Foyn* under *Onobrychis*, *Lucern* under *Medica*, *Ray Graſs* under *Gramen*, *Spurry* under *Spergula*, to which Articles the Reader is deſired to turn.

LANIGEROUS TREES, are ſuch as bear a Woolly or Downy Subſtance, as is commonly contain'd in the *Catkins* of the Willows, *&c.*

LANUGINOUS, ſignifies *Downy*, or to be *cover'd with a ſoft Down*, as a *Quince*.

LAPATHUM, [takes its Name of the *Greek* Word Λαπάζω, to *evacuate*, becauſe the Root of this Plant purges the Belly: One Species of it is call'd *Hippolapathum*, of ἵππος, an *Horſe*, and λάπαθον, as much as to ſay, *Great Lapathum*: and another is call'd *Patience*, of its gentle Virtue; and *Rhabarbarum Monachorum*, i. e. *Monks Rhubarb.*] The Dock.

The *Characters* are;

The Cup of the Flower conſiſts of ſix Leaves, three of which are large, and of a red Colour; the other three are leſſer, and green: in the Middle of the Cup are placed ſix Stamina: *the three outer ſmall Leaves of the Cup fall away when ripe; but the three inner large Leaves join together, and form a triangular Covering, in the Middle of which are contain'd ſhining three-corner'd Seeds.*

The *Species* are;

1. LAPATHUM *præſtantiſſimum, Rhabarbarum officinarum dictum. Mor. Hiſt.* The Pontick Rhubarb.

2. LAPATHUM *Alpinum, folio ſubrotundo. Mor. Hiſt.* Round-leav'd Alpine Dock, *by ſome call'd* Monks Rhubarb.

3. LAPATHUM *hortenſe, folio oblongo, ſive ſecundum Dioſcoridis. C. B. P.* Long-leav'd Garden-Dock or Patience.

4. LAPATHUM *folio acuto plano. C. B. P.* Sharp-pointed Dock.

5. LAPATHUM *folio acuto criſpo. C. B. P.* Curled ſharp-pointed Dock.

6. LAPATHUM *folio acuto rubente. C. B. P.* Bloodwort or ſharp-pointed Dock, with red Veins and Footſtalks to the Leaves.

7. LAPATHUM *folio acuto, flore aureo. C. B. P.* Sharp-pointed Dock, with golden Flowers.

8. LAPATHUM *acutum minimum. J. B.* The leaſt ſharp-pointed Dock.

9. LAPATHUM *vulgare, folio obtuſo. J. B.* Common broad-leav'd Dock, vulgarly called the Butter Dock.

10. LAPATHUM *ſylveſtre, folio ſubrotundo, ſeminis involucris dentatis nobis. Mor. Hiſt.* Common broad-leaved Dock, with indented Covers to the Seeds.

11. LAPATHUM *aquaticum, folio cubitali. C. B. P.* Great Water Dock.

12. LAPATHUM *aquaticum minus. C. B. P.* Leſſer Water Dock.

13. LAPATHUM *pulchrum Bononienſe ſinuatum. J. B.* The Fiddle Dock.

14. LAPATHUM *hortenſe latifolium. C. B. P.* The true Monks Rhubarb.

15. LAPATHUM *Chalepenſe, folio acuto, ſeminum involucris profunde dentatis. Mor. Hiſt.* Sharp-pointed *Aleppo* Dock, with the Seed-covers deeply indented.

16. LAPATHUM *Ægyptiacum annuum, parietariæ folio, capſula ſeminis longius barbata. Hort. Piſ.* Annual *Egyptian* Dock, with a pellitory Leaf, and long Beards to the Seed-veſſels.

17. LAPATHUM *Orientale, folio latiſſimo undulato & mucronato, ſive Rhabarbarum verum.* The true Rhubarb.

The firſt of theſe Plants is by ſome ſuppoſed to be the true *Rhubarb*: But that does not appear, from the Figure and Conſiſtence of the Roots, which in this Plant, however cultivated with us, is not of the ſame Colour; nor has it ſuch a Reſin as is found in the true; and the Shape of the Roots appears very different, as is alſo the Strength in Medicine: ſo that until the true Rhubarb is better known, there can little be ſaid with Certainty on this Head.

The ſecond Sort is ſometimes cultivated in Gardens, for Medicinal Uſe; tho' there is a Diſpute whether this be the true *Monks Hood*, or not: but there is no great Difference between the Roots of this Plant, and the other diſputed Sort; ſo that either may be indifferently uſed.

The third Sort was formerly cultivated in Gardens as a Pot-herb; but of late Years it has been wholly diſuſed for that Purpoſe, and now only preſerv'd in Gardens for Medicinal Uſe.

The Sorts from the fourth to the thirteenth grow wild in many Parts of *England*, and are ſeldom admitted into Gardens; but as ſeveral of theſe are uſed in Medicine, ſo I have put down the Names by which they are diſtinguiſhed amongſt the Botaniſts. The fourth and ſixth Sorts are directed by the College of Phyſicians, to be uſed in Medicine; but the People who ſupply the Markets, take the Roots of all the Sorts promiſcuouſly as they find them. Theſe two Sorts grow near Hedges, and in ſhady Lanes, which are not much frequented, in moſt Parts of *England*; but the ſixth Sort is leſs common than the fourth, from which it differs in nothing but the Stalks and the Veins of the Leaves being red.

The Roots of the eleventh Sort are alſo uſed in Medicine; this is the Plant which *Muntingius*, a curious Botaniſt of *Groningen* in *Holland*, ſuppoſes to be the *Herba Britannica* of the Ancients, which was found to be a ſovereign Remedy for the *Scurvy*. This Sort grows frequently in ſtanding Waters, where it produces Leaves two and a half or three Feet in Length. When this Sort is planted on dry Land, or the Water drained off the Ground, where it naturally grows, it will not riſe to near the Size of thoſe Plants which grow in deep Waters.

The fourteenth Sort, whoſe Roots are uſed in Medicine, and is the true *Monks Rhubarb*, is not common in *England*; ſo that thoſe who uſe Roots of *Engliſh* Growth, are ſupplied with the *Patience Dock*, or the *round-leaved Alpine Dock*, both which Sorts are cultivated in the *Engliſh* Gardens.

The fifteenth and ſixteenth Sorts are Foreigners, which have been introduced by the Curious in Botany for the ſake of Variety; but they are not uſed in Medicine, and as they are Plants of no great Beauty, ſo they do not merit a Place unleſs in Botanick Gardens for the ſake of Variety. The fifteenth Sort will continue two or three Years, but the ſixteenth Sort is an annual Plant.

The Seeds of the ſeventeenth Sort I received for the true *Rhubarb*: Theſe were gathered by a Gentleman who was on the Spot, where the Roots are taken up, and ſent to *Peterſburgh* in *Muſcovy*, for the Supply of *Europe*; ſo that there is no great Reaſon to doubt of its being the true Kind. This Sort is extremely hardy; for the Seeds were ſown in the full Ground, where the Plants came up, and have remained, without any other Care but to keep them clear from Weeds: ſo that, when we can obtain Seeds from theſe Plants, it may be ſown for Uſe, ſince it appears to be equally hardy with our common Docks, and there is little Reaſon to fear that it may be equal in Goodneſs to the Foreign Rhubarb.

All the Sorts of Dock are propagated by Seeds, which ſhould be ſown in Autumn, ſoon after they are ripe; for when the Seeds are kept out of the Ground until Spring, they will remain a whole Year in the Ground before the Plants appear; whereas thoſe ſown in Autumn, will come up the following Spring. Where the Seeds of the true Rhubarb (or any of the other Sorts, whoſe Roots are uſed in Medicine) are ſown to propagate the Plants, they ſhould have a Soil rather moiſt than dry, and of a pretty good Depth, that the Roots may have Room to run down. The Seeds ſhould be ſown thin; and in the Spring, when the Plants come up, they ſhould be hough'd out, after the manner directed for *Parſnips* and *Carrots*, leaving the large growing Kinds (as the true Rhubarb, *Rhapontic*, and *Alpine* round-leaved Dock) two Feet and a half aſunder at leaſt, becauſe theſe produce very large ſpreading Leaves, and if they have not ſufficient room to grow, the Roots will be ſmall. When this is done, the Plants will require no other Management, but to keep them clear from Weeds; and in two or three Years Time the Roots will be fit for Uſe, when they ſhould be taken up ſoon after their Leaves decay in Autumn, and dried in a ſhady Place, where the Air may paſs freely between them. But it will be well worth trying, whether thoſe Plants whoſe Flower-ſtems are pinched off, ſoon after they appear in Spring, (ſo are never ſuffered to flower or ſeed) do not produce better Roots, than thoſe which are permitted to ſeed, becauſe we find moſt other Roots grow ſticky and tough after they have ſeeded, and are not near ſo good for Uſe as before; and as theſe Plants frequently ſend out Flower-ſtems the ſecond Year, ſo it may be neceſſary to prevent their Growth in order to encourage their Roots.

LARIX, [ſo call'd of λάρος, *ſweet*, becauſe its Leaves ſend forth a ſweet Savour] The Larch-Tree.

The *Characters* are;

The Leaves (which are long and narrow) are produced out of little Tubercles, in Form of a Painter's Pencil, (as in the Cedar of Libanus) *but fall off in Winter: the Cones are ſmall and oblong, and (for the moſt part) have a ſmall Branch growing out of the Top; theſe are produced at remote Diſtances from the Male Flowers on the ſame Tree: the Male Flowers are (for the moſt part) produced on the under Side of the Branches, and, at their firſt Appearance, are very like ſmall Cones.*

The *Species* are;

1. LARIX *folio deciduo, conifera. J. B.* The Larch-Tree.
2. LARIX *folio deciduo, rudimentis conorum candidiſſimis. Pluk. Alm.* Larch-Tree, with white Rudiments, or rather, with white Male Flowers.

The firſt of theſe Trees is now pretty common in *Engliſh* Gardens: this is a Native of the *Alps* and *Pyrenæan* Mountains, but thrives exceeding well here, eſpecially if it be planted upon an elevated Situation: as may be obſerv'd by thoſe which were planted a few Years ſince at *Wimbleton* in *Surrey*, which are now grown to be large Trees, and produce annually a large Quantity of Cones.

The ſecond Sort ſeems to be only a ſeminal Variety from the firſt, from which it differs in the Colour of the Male Flowers, which in this is White, but in the other of a bright Red Colour; as alſo in the Colour of the Leaves, which in this Sort are a ſomewhat lighter Green than thoſe of the other; nor do the Trees of this Kind ſeem to be ſo vigorous: but whether the Seeds of this Kind will produce the ſame, I can't as yet ſay, having never ſeen any of the Plants which were raiſed from theſe Seeds produce any Flowers; but however, it may be obtain'd by inarching it into the common Sort.

Theſe Trees are propagated by Seeds, which ſhould be ſown in the Beginning of *March*, upon a Bed of light Soil, expoſed only to the Morning Sun: or otherwiſe, it may be ſown in Pots or Boxes of light Earth, and placed near a Hedge, where they may have the Morning Sun only. The Seeds ſhould be cover'd about half an Inch thick with fine light Earth, and in very dry Weather ſhould be gently refreſh'd with Water. In about ſix Weeks, if your Seeds were good, the Plants will come up, at which Time you ſhould carefully guard them againſt the rapacious Birds, who would otherwiſe pull off the Heads of the Plants, as they thruſt themſelves out of the Ground with their Covers on them; and obſerve to refreſh them with Water in dry Weather, eſpecially if they are ſown in Pots or Boxes, as alſo to keep them conſtantly clear from Weeds, which, if ſuffer'd to grow among the young Plants, will ſoon deſtroy them: nor ſhould they be too much expoſed to the Sun, or ſtrong Winds, both which are very injurious to theſe Plants while they are young: but in *October* you ſhould (if they are in Boxes or Pots) remove them into a Situation where they may be defended from ſharp Winds, which are ſometimes hurtful to them while young; but afterwards they will endure the ſevereſt Weather of our Climate.

The latter End of *March*, or Beginning of *April* following, you ſhould remove theſe Plants into Beds of light freſh Earth, at about ten Inches diſtance each Way, obſerving to water them, if the Seaſon ſhould prove dry, as alſo to lay a little Mulch upon the Surface of the Ground, to prevent the Sun and Winds from drying their Roots: in theſe Beds they may remain two Years, during which Time you ſhould carefully keep them clear from Weeds; as alſo obſerve if any of them incline their Heads downward, to thruſt a ſmall Stake into the Ground by ſuch of them, and faſten their Heads upright thereto; for if they are ſuffer'd to grow on one-ſide while young, they are rarely to be reduced to an upright Figure again.

When the Plants have remain'd in theſe Beds two Years, they will be fit to tranſplant into the Nurſery; in order to which, you ſhould make choice of a Piece of freſh light Earth, not over-dry, nor too wet: this Ground ſhould be well dug, and cleans'd from Weeds, and Roots of Plants or Trees; and, after having laid it level, you ſhould mark out the Rows at three Feet diſtance; then you ſhould take up the Plants carefully, preſerving a good Ball of Earth to their Roots, and plant them in the Lines at eighteen Inches aſunder, obſerving to mulch their Roots, and alſo to water them, to preſerve their Roots from drying. The beſt Seaſon for this Work is toward the latter End of *March*, or Beginning of *April*, juſt before the Plants begin to ſhoot; for if they are removed ſooner, they ſeldom ſucceed ſo well. During the Time they remain in this Nurſery, they muſt conſtantly be kept clean from Weeds; and the Ground between them ſhould be dug every Spring, that it may be looſe for the Fibres of their Roots to ſtrike into; and the Weeds will be hereby more effectually deſtroy'd than by any other Method: and the Roots of the Plants being annually cut round, will cauſe them to puſh out a greater Number of Fibres, whereby they will be much ſafer to remove than they would be if permitted to grow undiſturb'd for ſeveral Years.

You muſt alſo obſerve to train their Heads upright, and not ſuffer them to grow awry, which they are naturally too much inclin'd to: but I would by no means adviſe the ſheering them into Pyramids, (as is too often practiſed) but rather lead them up for Timber Trees; for they will grow to a conſiderable Size, provided they like the Soil they are planted in.

In removing theſe Trees from the Nurſery to the Places where they are deſign'd to be continued, you ſhould always obſerve to do it juſt before they ſhoot out in the Spring, as alſo to take them up with a large Ball of Earth to their Roots; and when planted, the Ground ſhould be mulch'd, and the Plants ſtak'd, to prevent the Wind from looſening them, or blowing them out of the Ground. Theſe Directions, if duly executed, will be ſufficient, and there will be no Danger of not ſucceeding. But the chief Cauſe why many of theſe Trees have fail'd, upon their being remov'd, was, the not doing it in a proper Seaſon, or elſe that they were not carefully taken up.

Theſe Trees are very proper for the Sides of barren Hills, where few other Sorts will thrive ſo well; and during the Summer they appear very beautiful; but in Autumn they caſt their Leaves, whereby ſome People have been deceiv'd, by ſuppoſing them dead, and have deſtroy'd them.

From the wounded Bark of this Tree exſudes the pureſt *Venice Turpentine*; and on the Body and Branches of it grows the *Agaric*, which is a Drug uſed in Medicine: and the Wood is very durable, and (by ſome) reported to be very difficult to burn. But I don't know how this ſhould be, to a Tree which abounds with Turpentine; tho' it is ſaid alſo to be ſo ponderous as to ſink in Water. It will poliſh exceeding well, and is by the Architects abroad much coveted, both for Houſes, and building of Ships. *Witſen*, a *Dutch* Writer upon *Naval Architecture*, mentions a Ship to be long ſince found in the *Numidian Sea*, 12 Fathoms under Water, being chiefly built of this *Timber*, and *Cypreſs*, both which Woods were reduced to that Hardneſs, as to reſiſt the ſharpeſt Tools; nor was any Part of it periſh'd, tho' it had lain above a Thouſand Years ſubmerg'd. And it was upon Tables of this Wood that *Raphael*, and ſeveral of the greateſt Artiſts, eterniz'd their Skill, before the Uſe of Canvas was introduced.

There is a particular Sort of this Tree, which was brought from *America*, which is growing in the Garden of Mr. *Peter Collinſon* at *Peckham* in *Surrey*, which differs from the *European* Kind, in having darker Shoots. This Kind I do not find mentioned by the Botaniſts, nor has it been long known in *Europe*, tho' it grows plentifully in ſome of the Northern Parts of *America*. This doth not promiſe to make ſo large Trees as the *European* Kind, ſo ſhould be planted with Trees of lower Growth to form Clumps and Amphitheatres, where it will make a Variety in Summer, when its green Leaves appear. It may be propagated by Seeds, after the ſame Manner as hath been directed for the *European* Kind, and being a Native of cold Countries, will endure the ſevereſt Cold of this Climate.

LARKSPUR. *Vide* Delphinium.

LASERPITIUM, [takes its Name of *Lacerare*, Lat. to *tear*; becauſe Inciſions being made in the Stalks and Roots of this Plant, a Juice diſtils, which is ſaid to be *Aſſa fœtida* and *Opoponax*. It is alſo call'd *Thus Libanotis*, becauſe the Root of this Plant has the Smell of Frankincenſe] Laſerwort.

This is a kind of Umbelliferous Plant, of which there are ſeveral Sorts preſerv'd in curious Botanick Gardens: but as they are Plants of little Beauty or Uſe in *England*, I ſhall omit mentioning them in this Place.

LATHYRUS, Chichling Vetch.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, cover'd with a membranaceous Sheath, which afterwards becomes a Pod, ſometimes round, ſometimes cylindrical, and at other times angular: to which may be added, it hath a compreſs'd Stalk, with a raiſed Rib, and a leafy Border; and has only one Pair of Leaves, growing on the Nerves, which terminates in a Tendril.

The *Species* are;

1. LATHYRUS *latifolius*. *C. B.* Broad-leav'd *or* common Everlaſting Peas.
2. LATHYRUS *latifolius minor, flore majore. Boerh. Ind.* Leſſer Broad-leav'd Everlaſting Peas, with a larger Flower.
3. LATHYRUS *major Narbonenſis anguſtifolius. C. B.* Greater narrow-leav'd Everlaſting Peas.
4. LATHYRUS *arvenſis repens tuberoſus. C. B.* Creeping Chichling, *or* Peas Earth-Nut, with a tuberoſe Root.
5. LATHYRUS *Tingitanus, ſiliquis orobi, flore amplo ruberrimo. Mor. Hiſt.* Tangier Chichling, with a large deep-red Flower.
6. LATHYRUS *diſtoplatyphyllus hirſutus mollis, magno & peramœno flore odoro. Hort. Cath.* Broad-leav'd, hairy, ſoft Chichling, with a large and very beautiful purple ſweet-ſmelling Flower, *commonly call'd* Sweet-ſcented Peas.
7. LATHYRUS *ſativus, flore fructuque albo. C. B. P.* Garden Chichling Vetch, with white Flowers and Fruit.
8. LATHYRUS *ſativus, flore purpureo. C. B. P.* Garden Chichling Vetch, with a purple Flower.
9. LATHYRUS *ſylveſtris major. C. B. P.* Great wild Chichling Vetch.
10. LATHYRUS *ſylveſtris major, flore atro purpureo. Inſt. R. H.* Great wild Chichling Vetch, with a dark purple Flower.
11. LATHYRUS *latifolius, flore albo. Inſt. R. H.* Everlaſting Pea, with a white Flower.
12. LATHYRUS *anguſtifolius, ſemine maculoſo. C. B. P.* Narrow-leaved Chichling Vetch, with a ſpotted Seed.
13. LATHYRUS *anguſtiſſimo folio, Americanus variegatus. C. B. P.* The moſt narrow-leaved American Chichling Vetch, with a variegated Flower.
14. LATHYRUS *annuus, flore cœruleo, ochri ſiliqua. H. L. B.* Annual Chichling Vetch, with a blue Flower, and a Pod ſhaped like Ochrus.
15. LATHYRUS *Bæticus, flore luteo. Park. Theat.* Spaniſh Chichling Vetch, with a yellow Flower.
16. LATHYRUS *luteus latifolius. Bot. Monſp.* Broad-leaved yellow Chichling Vetch.
17. LATHYRUS *anguſtifolius, ſiliquâ hirſutâ. C. B. P.* Narrow-leaved Chichling Vetch, with a hairy Pod.
18. LATHYRUS *latifolius annuus, ſiliquâ articulatâ hirſutiore. H. R. Par.* Broad-leaved annual Chichling Vetch, with a very rough jointed Pod.
19. LATHYRUS *anguſtiſſimo folio, ſemine rotundo. H. R. Par.* Narrow-leaved Chichling Vetch, with a round Seed.
20. LATHYRUS *anguſtiſſimo folio, ſemine anguloſo. H. R. Par.* Narrow-leaved Chichling Vetch, with an angular Seed.

The three firſt Sorts are abiding Plants, which ſend forth ſtrong downright Roots very deep into the Earth; for which Reaſon they ſhould not be often remov'd, which would prevent their growing ſtrong, or producing many Flowers.

They are propagated by Seeds, which ſhould be ſown in the Beginning of *March*, upon a Bed of light freſh Earth, covering them about half an Inch deep. But the beſt Method is, to make a ſhallow Drill in the Ground, and then drop the Seeds therein, about ſix Inches diſtance: theſe Drills ſhould be a Foot aſunder, for the Conveniency of houghing and cleaning the Ground between them; which muſt conſtantly be done, otherwiſe the Weeds will over-bear and deſtroy them: but they will require no farther Care, being very hardy Plants, until the Spring following, at which Time, (*viz.* in *March*) juſt before they begin to ſhoot, the Roots ſhould be carefully taken up, and tranſplanted where they are to continue, placing them at leaſt two Feet aſunder, otherwiſe they will overrun each other, or whatever other Plants ſtand near them. If the Seaſon ſhould prove dry, you muſt give them ſome Water, to ſettle the Earth to their Roots; which ſhould be now and then repeated if it continue dry Weather, until the Plants have taken Root: after which, they will require no farther Culture but to keep them clear from Weeds, and in the Summer-time to ſupport them with ſtrong Stakes, otherwiſe they will trail upon the Ground, and rot the Branches, and deſtroy whatever Plants grow near them.

Theſe Plants are very proper to plant againſt a dead Hedge, where they will run over it, and if they be kept train'd up, will cover it in the Summer, and in ſuch Places they will produce great Quantities of Flowers; but if they are planted in a Flower-Garden, they muſt have a great deal of Room, and in Summer ſhould have very ſtrong Stakes placed down by them, to which they muſt be cloſely faſten'd, otherwiſe they will ramble and trail upon the Ground, and appear very unſightly; for if the Ground be good in which they are planted, and the Roots are very ſtrong, they will ſometime grow eight or ten Feet high in a Seaſon, and produce Abundance of Flowers, which are very ornamental in Baſons or Pots of Flowers, to place in Chimnies or other Parts of large Rooms. Theſe produce their Flowers in *June* and *July*, and their Seeds are perfected in *Auguſt*; their green Leaves decay in Autumn, and riſe again the ſucceeding Spring, their Roots continuing good for many Years: They delight moſt in a light Soil, not too dry nor over wet; but will grow in almoſt any Soil or Situation, but beſt in that which is expos'd to the Sun.

The firſt Sort is moſt commonly cultivated in the *Engliſh* Gardens, but the ſecond is much preferable to that, as being of humbler Growth, never riſing above five Feet high, and ſo is more proper for Flower-Gardens, and the Flowers are much larger, and of a deeper red Colour, and commonly are produced in larger Cluſters. The third Sort is ſeldom propagated in Flower-Gardens, tho' for Variety it ſhould have a Place amongſt other large Plants. The Flowers of this Kind are ſmaller, and of a purple Colour.

The tuberoſe-rooted Sort is preſerv'd as a Curioſity in many Gardens, tho' there is no great Beauty in its Flowers. This may be propagated either by Seeds, as the others, or by its Roots, which increaſe very faſt under Ground, and is an abiding Plant, but ſhould not be placed among other curious Flowers; for the Roots propagating under Ground, will come up and ſpread over whatever Plants grow near them.

The fifth and ſixth Sorts are annual Plants, which are propagated only by Seeds: Theſe may be ſown in *March*, in the Places where they are to remain for good, being Plants that ſeldom will grow, if tranſplanted, except it be done while they are very young: Theſe ſhould be either ſown near a Pale, Wall, or Eſpalier, to which they may be train'd; or if ſown in the open Borders, ſhould have Stakes placed by them, to which they ſhould be faſten'd, otherwiſe they will trail upon the Ground, and appear very unſightly, which is the only Culture theſe Plants require, except the clearing them from Weeds. They produce their Flowers in *July*, and their Seeds are perfected in *Auguſt* and *September*.

But the beſt Method to have them very ſtrong, is, to ſow their Seeds in *Auguſt*, under a warm Wall or Hedge, where they will come up in Autumn, and abide the Winter very well; and theſe will begin to flower in *May*, and continue to ſpread freſh Flowers until *July*, or later, according to the Heat of the Seaſon: And one of theſe Autumnal Plants will be as large as four or five of thoſe ſown in the Spring, and produce ten Times the Number of Flowers; and upon theſe

Plants you will always have good Seeds, when ſometimes the other will miſcarry: However, it is very proper to ſow their Seeds at two or three different Seaſons, in order to continue their Flowers the longer; for the late planted ones will continue blowing until the Froſt prevents them.

The ſweet-ſcented Sort is the moſt valuable, both for the Beauty and Fragrancy of its Flowers.

The ſeventh Sort is frequently cultivated for Uſe in ſeveral Parts of *Europe*; but in *England* it is rarely to be met with, unleſs it be in botanick Gardens, where it is preſerved for the ſake of Variety. This Plant may be cultivated in the ſame Manner as *Tares*, and may be uſed for the ſame Purpoſes; but the beſt Method is to ſow them in Drills about eighteen Inches aſunder, and ſo keep the Ground houghed with a Plough to deſtroy the Weeds between the Rows, in the ſame Manner as is practiſed for Peas; by which Method the Plants will thrive exceedingly, and become a great Improvement to poor ſandy Land.

The eighth Sort is a Variety of the ſeventh, from which it only differs in the Colour of the Flower, this having a fine purple Flower, and is by many Perſons ſowed in Gardens by Way of Ornament. If the Seeds of this Sort are ſowed in Autumn, the Plants will come up, and abide the Winter very well; ſo will flower the following *May*; but if the Seeds are ſown in the Spring, the Plants will not flower 'till *July* or *Auguſt*: So that by ſowing at the two different Seaſons, theſe may be continued in Beauty for ſeveral Months.

The ninth Sort has been by ſome Perſons ſown for Feed for Cattle; but it doth not anſwer near ſo well for this Purpoſe as the ſeventh Sort, ſo is not worth Cultivating. The tenth Sort is a Variety of the ſeventh, from which it differs in the Colour of the Flower; ſo is preſerved by the Curious in Botany, for the ſake of Variety.

The eleventh Sort is a Variety of the common *Everlaſting Pea*; the Flowers of this being white, are preſerved by ſeveral Perſons for the Variety; but it is not ſo beautiful as the common Sort. This may be propagated in the ſame Manner as is directed for the common Sort.

The nine following Sorts are preſerved in ſome curious Gardens, for the Variety of their Flowers. Theſe may all of them be propagated by ſowing of their Seeds, either in Spring or Autumn; but thoſe which are ſowed in Autumn, ſhould have a light Soil, and a warm Situation, where the Plants will abide the Winter, and come to flower early the following Spring, and their Seeds will ripen in *July*. But thoſe which are ſown in the Spring, ſhould have an open Expoſure, and may be planted upon almoſt any Soil; for they are not very tender Plants in their Culture. Theſe Sorts ſhould all of them be ſown where they are deſigned to remain, for they ſeldom ſucceed when they are tranſplanted; ſo that where they are ſown for Ornament, there ſhould be ſix or eight Seeds ſown in a ſmall Patch, in different Parts of the Borders of the Flower-Garden; and when the Plants come up, they ſhould be carefully kept clear from Weeds; and when they are grown two or three Inches high, there ſhould be ſome Sticks put down by them to ſupport them; otherwiſe they will trail on the Ground, and become unſightly; beſides, they will trail on whatever Plants grow near them.

The twelfth and the twentieth Sorts, I have ſeen cultivated in ſome Kitchen-Gardens for the Table, and are by the People in ſome Parts of *Germany* conſtantly eaten as Peas; but as they are not near ſo tender or well-taſted as Peas, ſo I believe few Perſons in *England* will ever cultivate them for that Purpoſe.

LATIFOLIOUS *Trees* and *Plants*, are ſuch as have broad Leaves.

LAVATERA, [takes its Name of the Phyſician *Helveticus Lavaterus*, the Friend of Monſ. *Tournefort*; upon which Account, *Tournefort* ſo intituled it. *Vaillantius* thought it to be the *Trimiſtrei Cluſii*: But then it ought rather to be referr'd to the Genus of *Alcea*.]

The *Characters* are;

The Leaf, Flower, Style, and Cup of the Flower have the Appearance of a Mallow: *The Stile becomes a Fruit, which is arm'd in Front with a hollow Shield; the Seeds, which are ſhaped like a Kidney, growing to the inner Part.*

The *Species* are;

1. LAVATERA *folio & facie althææ. Tourn.* Lavatera with the Leaf and Face of Marſhmallow.

2. LAVATERA *folio & facie althææ, flore albo.* Lavatera with the Leaf and Face of Marſhmallow, and a white Flower.

3. LAVATERA *Africana, flore pulcherrimo. Boerb. Ind.* *African* Lavatera, with a moſt beautiful Flower.

Theſe are all annual Plants, which are propagated by Seeds: The Seaſon for ſowing them is in *March*, upon a Bed of freſh light Earth; and when the Plants are come up, you muſt carefully clear them from Weeds; and in very dry Weather, they muſt be now and then refreſh'd with Water. When they are about two Inches high, you muſt tranſplant them into the Places where they are deſign'd to remain, which ſhould be in the Middle of the Borders in the Flower-Garden; for if the Soil be good, they will grow two or three Feet high: In tranſplanting them, you muſt take them up very carefully, preſerving a Ball of Earth to their Roots, otherwiſe they are apt to miſcarry: And alſo water and ſhade them until they have taken Root; after which they will require no other Care but to clear them from Weeds, and to faſten them to Stakes, to prevent their being injur'd by ſtrong Winds. You may alſo ſow their Seeds in Autumn; and when the Plants are come up, you ſhould tranſplant them into ſmall Pots, which towards the End of *October*, ſhould be placed into a common Hot-bed Frame, where the Plants being defended from ſevere Froſts, will abide the Winter very well; and in the Spring, you may ſhake them out of the Pots, and plant them into larger, or elſe into the full Ground, where they may remain to flower: The Plants thus manag'd, will be larger, and flower ſtronger and earlier than thoſe ſown in the Spring, and from theſe you will conſtantly have good Seeds; whereas thoſe ſown in the Spring do ſometimes miſcarry.

Theſe produce their Flowers in *June*, *July*, and *Auguſt*, and their Seeds ripen ſoon after.

They are very ornamental Plants in a fine Garden, when placed among other Annuals, either in Pots or Borders: Their Flowers are very like thoſe of the *Mallow*, but are larger, and of a more beautiful Colour.

LAVENDULA, [takes its Name of *Lavando*, Lat. *waſhing*, becauſe it was uſed to be thrown into Baths, for the Fragrancy of the Scent; or becauſe uſed in Lye, to give a Fragrancy to Linen; and becauſe it is very good to waſh the Face with, and give it both Beauty and a grateful Scent] Lavender.

The *Characters* are;

It is one of the verticillate Plants, whoſe Flower conſiſts of one Leaf, which is divided into two Lips; the upper Lip ſtanding upright, is roundiſh, and for the moſt part bifid; but the under Lip is cut into three Segments, which are almoſt equal: Theſe Flowers are diſpoſed in Whorles, and are collected into a ſlender Spike upon the Top of the Stalks.

The *Species* are;

1. LAVENDULA *latifolia. C. B.* Common broad-leav'd Lavender.

2. LAVENDULA *anguſtifolia. C. B.* Common narrow-leav'd Lavender, *commonly called* Spike Lavender.

3. LAVENDULA *latifolia ſterilis. Mor. Hiſt.* Broad-leav'd barren Lavender.

4. LAVENDULA *anguſtifolia, flore albo. C. B. P.* Narrow-leav'd Lavender, with white Flowers.

5. LAVENDULA *folio diſſecto. C. B.* Cut-leav'd Lavender.

6. LAVENDULA *folio diſſecto, flore albo. Boerb. Ind.* Cut-leav'd Lavender, with a white Flower.

7. LAVENDULA *folio longiori, tenuius & elegantius diſſecto. Tourn.* Lavender with a longer and more beautiful fine cut Leaf, *commonly called* Canary Lavender.

8. LAVENDULA *latifolia Indica ſubcinerea, ſpicâ breviore. H. R. Par.* Broad-leav'd *Indian* Lavender, with a ſhort Spike.

9. LAVENDULA *latifolia Hiſpanica tomentoſa. Inſt. R. H.* Broad-leav'd woolly *Spaniſh* Lavender.

10. LAVENDULA *latifolia, flore albo. C. B. P.* Broad-leav'd Lavender, with a white Flower.

The firſt of theſe Species, tho' very common in moſt Parts of *Europe*, yet in *England* is rarely to be found, notwithſtanding it is as eaſily propagated as any of the other Sorts.

The ſecond is the moſt common Sort in the *Engliſh* Gardens, being propagated for Medicinal Uſes, *&c.*

The third Sort is a Degeneracy from the ſecond, having much broader and greener Leaves, but rarely ever flowers while it continues with the Leaves broad; but whenever it flowers, the Leaves of that Part of the Plant become narrow again.

The fourth Sort is alſo a Variety of the ſecond, from which it differs in the Colour of the Flowers, which in this Sort are white, and thoſe of the ſecond are blue.

All the Sorts are propagated by Cuttings or Slips; the beſt Seaſon for which is in *April*, when you ſhould plant them in a ſhady Situation, or at leaſt ſhade them with Mats until they have taken Root; after which they may be expoſed to the Sun, and when they have obtain'd Strength, may be remov'd to the Places where they are deſign'd to remain. Theſe Plants will abide the longeſt in a dry, gravelly, or ſtony Soil, in which they will endure our ſevereſt Winters, tho' they will grow much faſter in the Summer, if they are planted upon a rich light moiſt Soil; but then they are generally deſtroy'd in Winter; nor are the Plants half ſo ſtrong ſcented, or fit for Medicinal Uſes, as thoſe which grow upon the moſt barren rocky Soil.

The firſt and ſecond Sorts may alſo be propagated from Seeds, which ſhould be ſown in *March*, upon a dry undung'd Soil; and when the Plants are come up, they muſt be carefully clear'd from Weeds, until they are about two Inches high, when they ſhould be tranſplanted into other Beds, allowing them a Foot diſtance each Way: In theſe Beds they may remain, to be cut for Uſe; or you may afterwards tranſplant them into dry Borders or Beds, in any other Place where you would have them ſtand, obſerving never to dung the Ground where they are planted, which would cauſe them to grow vigorouſly in Summer, but will haſten their Decay, as was before obſerv'd.

Theſe Plants were formerly in Uſe to make Edgings to Borders in Gardens; for which Purpoſe they are by no means proper, for they will grow too large for ſuch Deſigns; and if they are often cut in very dry Weather, they are ſubject to decay, and in hard Winters they are very often kill'd, ſo that the Edging will not be compleat; beſides, theſe Plants do greatly exhauſt the Goodneſs of the Soil, whereby the Plants in the Borders will be depriv'd of their Nouriſhment; ſo that they ſhould never be planted in a fine Garden, amongſt other choice Plants or Flowers, but rather be placed in Beds in the Phyſick-Garden. Theſe Plants produce their Flowers in *June* and *July*, at which Time they ſhould be gather'd and dry'd in a ſhady Place, and preſerv'd dry for Uſe.

The fifth, ſixth, and ſeventh Sorts are commonly ſown every Spring, on Borders or Beds of light freſh Earth; and when the Plants come up, they may be tranſplanted into other Borders of the Flower-Garden, or into Pots, to remain for good, where they will produce their Flowers in *July* and *Auguſt*, and their Seeds are ripe ſoon after. Theſe are pretty Plants to place in large Borders, amongſt other Plants, for Variety; but they are never uſed with us: they may alſo be preſerv'd over the Winter, if placed into a Green-houſe in Autumn, which is the ſureſt Method to obtain good Seeds from the ſeventh Sort, which rarely ripens Seeds the firſt Year; but they ſeldom continue longer than two Years with us, and many Times (if they have produced Seeds the firſt Year) they will not continue longer. Theſe Plants will ſometimes grow from Cuttings, but then the Cuttings muſt be ſtrong, and inclinable to be woody; for if they are very ſoft and ſpungy, they ſeldom ſucceed; and they ſhould alſo be placed upon a moderate Hot-bed, which will greatly promote their taking Root. This Method is ſometimes neceſſary to preſerve the Sorts, which might otherwiſe be in Danger of being loſt.

The eighth, ninth, and tenth Sorts are diſtinguiſhed by moſt Writers in Botany; but I believe the eighth Sort to be the ſame with the broad-leav'd barren Lavender, which is a Degeneracy from the common Sort; for by planting Slips or Cuttings of this Sort, they will often alter, and become narrow-leav'd, when the Plants will produce Flowers in as great Plenty as the common Sort, tho', while they continue to have broad Leaves, they do not produce any Flowers.

The ninth Sort is not common in *England*; this was found by Dr. *Tournefort* in *Spain*. The tenth Sort is a Variety of the common broad-leav'd Kind, from which it only differs in the Colour of the Flower.

LAUREOLA. *Vide* Thymelea.

LAUROCERASUS, [this Plant is thus call'd, becauſe it has the Appearance of the *Laurel*, and the Fruit of a *Cherry*] The Laurel *or* Cherry-Bay.

The *Characters* are;

It hath broad, thick, ſhining, ever-green Leaves, ſomewhat like thoſe of the Bay-tree: *The Cup of the Flower is hollow and Funnel-ſhaped, ſpreading open at the Top, and is divided into five Parts: The Flower conſiſts of five Leaves, which expand in form of a* Roſe, *having many* Stamina *in the Center: The Fruit (which are like thoſe of the* Cherry-tree) *are produced in Bunches, and the Stone is longer and narrower than that of the* Cherry.

The *Species* are;

1. LAUROCERASUS. *Cluſ. Hiſt.* The common Laurel *or* Cherry-Bay.
2. LAUROCERASUS *foliis ex albo variegatis. Cat. Plant. Angl.* The White-ſtrip'd Laurel.
3. LAUROCERASUS *foliis ex luteo variegatis. Cat. Plant. Angl.* The Yellow-ſtrip'd Laurel.
4. LAUROCERASUS *Luſitanica, minor. Tourn.* The Dwarf *Portugal* Laurel, *called* Aſarero.

The firſt Sort is very common in moſt *Engliſh* Gardens, and was formerly in greater Requeſt than it is at preſent, when theſe Trees were planted againſt North Walls, to cover them; as alſo in the Parterre-Garden, where they were frequently ſheer'd up, to form Pyramids and Globes; for which Purpoſe, this was one of the moſt improper Trees; for the Leaves being very large, they were cut in divers Places by the Sheers, which render'd them unſightly; but tho' this Plant is very improper for ſuch Uſes, yet it is valuable for planting upon the Sides of cold barren Hills, where it will grow to a large Magnitude, and make a fine Appearance thro' the whole Year, and in ſuch Situations it will riſe to a large Tree.

They are eaſily propagated by planting Cuttings in *September*, in a ſhady moiſt Border, where they will ſoon take Root; and in the Spring following may be remov'd into the Nurſery, planting them three Feet diſtance, Row from Row, and two Feet aſunder in the Rows, obſerving to clear them from Weeds, and to dig the Ground annually between the Rows, and prune off their under Branches, to make them aſpire in Height; and when they have remain'd in this Place three Years, they will be fit to tranſplant into the Places where they are to continue. The beſt Seaſon for tranſplanting theſe Trees is in *April*, juſt before they begin to ſhoot; but in taking them up, you muſt always obſerve to preſerve a Ball of Earth to their Roots: and when they are planted, you muſt mulch the Ground round their Stems, to preſerve it from drying, and refreſh them often with Water, (eſpecially if the Seaſon be dry) until they have taken Root; after which, they will require but very little Culture.

But if you deſign theſe Trees for large Standards, the beſt Method is, to propagate them from the Berries, which will eaſily riſe, and will ſooner grow to large Trees than thoſe propagated by Cuttings. The Manner of ſowing theſe Seeds is as follows: You ſhould dig and prepare a Bed or two, (according to the Quantity of Seeds you have to ſow) and level the Ground very even; then ſow the Berries thereon ſoon after they are ripe, covering them over about an Inch thick with light Earth: In the Spring the young Plants will appear; at which Time you muſt carefully clear them from Weeds, and in dry Weather often refreſh them with Water, which will greatly promote their Growth: Theſe Plants (if they have made a good Progreſs) will be fit to tranſplant the ſucceeding Spring; when you muſt prepare ſome freſh Beds, into which they ſhould be remov'd, planting them ten Inches or a Foot aſunder each Way, obſerving to water them, and lay a little Mulch about their Roots: In theſe Beds they may continue two Years; after which, they ſhould be remov'd either into the Places where they are to remain, or into a Nurſery, as was before directed.

There are ſome People, who adviſe the budding of this Tree upon the common *Black-Cherry-Stock*, in order to render it more vigorous; but as I have never yet ſeen any large Trees which were thus raiſed, ſo I can't ſay how well it will ſucceed; tho' I have often ſeen the *Cherry* grafted on this Tree, and this grafted upon the *Cherry*, both which have taken very well; but I much doubt whether they will join ſo well together, as to add to the Stature of the Tree, eſpecially ſince we find that moſt Sorts of Fruit-Trees grow much larger when they are ſuffer'd to remain ungrafted as they come from Seeds, than thoſe which are budded or grafted.

The Berries of this Tree are by ſome put into Brandy to make Ratafia, for which Purpoſe it is greatly preferr'd to *Apricock* Stones, giving the Brandy a much pleaſanter bitter Taſte, and by ſome the Leaves are uſed for the ſame Purpoſe; but this ſhould be cautiouſly done, ſince, by ſome late Accounts from *Ireland*, we are inform'd, that the diſtill'd Water of theſe Leaves is found to be poiſonous. Whether this Account be true or not, a few Experiments will ſoon make appear.

Theſe Berries are much coveted by divers Sorts of Birds, for which Reaſon ſome of the Trees ſhould be planted in the Clumps, where you intend a Shelter for Birds to harbour, and their Leaves remaining always green, will be of great Uſe to theſe Inhabitants in Winter; ſo that ſuch Plantations will be well ſtor'd with *Black-birds*, *Thruſhes*, and many other

Sorts of Singing-Birds, to the no ſmall Pleaſure of ſuch Places.

The two variegated Kinds may be propagated by Cuttings, or by budding or grafting them on the plain Sort; but theſe muſt conſtantly be planted on a poor Soil, otherwiſe they will become plain again. Theſe are pretty Varieties amongſt other variegated Plants.

The *Portugal* Dwarf Laurel is ſomewhat tenderer than the common Sort, and is ſubject to be injur'd by ſevere Froſts, but will endure our ordinary Winters abroad very well. This is propagated in the ſame Manner as the common Sort, but will not grow near ſo large; however, it is very proper to intermix with Ever-greens of middling Growth, where, if it be planted on a dry Soil, and has a warm Situation, it will ſtand the Teſt of our Winters very well.

LAURUS, The Bay-Tree.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is ſhaped like a Tunnel, and divided into four or five Segments; the Male Flowers (which are produced on ſeparate Trees from the Female) have eight Stamina, *which are branched into Arms; the Ovary of the Female Flowers becomes a Berry, incloſing a ſingle Seed within a horny Shell, which is cover'd with a Skin.*

The *Species* are;

1. LAURUS *vulgaris. C. B.* The common Bay, with Male Flowers.
2. LAURUS *vulgaris, fœmina. Boerh. Ind.* The common Fruit-bearing Bay-tree.
3. LAURUS *vulgaris, folio elegantiſſime variegato aureo. Boerh. Ind.* The Gold ſtrip'd Bay-tree, *vulgo*.
4. LAURUS *vulgaris, folio undulato. H. R. Par.* The common Bay-tree, with waved Leaves, and Male Flowers.
5. LAURUS *vulgaris, folio undulato, fœmina. Boerh. Ind.* The Berry-bearing Bay-tree, with waved Leaves.
6. LAURUS *tenuifolia. Tab. Icon. Mas.* The narrow-leav'd Bay, with Male Flowers.
7. LAURUS *tenuifolia, fœmina. Boerh. Ind.* The narrow-leav'd Berry-bearing Bay-tree.
8. LAURUS *latiori folio. Lugd. Mas.* The broad-leav'd Bay-tree, with Male Flowers.
9. LAURUS *latifolia, fœmina. Boerh. Ind.* The broad-leav'd Berry-bearing Bay-tree.
10. LAURUS *Indica. Hort. Farneſ. Ald.* The broad-leav'd *Indian* Bay-tree, *commonly called* Wild Cinnamon.
11. LAURUS *Americana mas, foliis ſubrotundis, floribus in capitulum collectis. Houſt.* Male *American* Bay, with roundiſh Leaves, and Flowers collected in a Head.
12. LAURUS *Americana fœmina, foliis ſubrotundis, fructu albo umbellato. Houſt.* Female *American* Bay, with roundiſh Leaves, and white Fruit growing in an Umbel.

The firſt and ſecond Sorts are old Inhabitants of the *Engliſh* Gardens; and as they are Varieties obtain'd from the ſaid Seeds, ſo they are promiſcuouſly cultivated, and are not to be diſtinguiſh'd aſunder, until they have produced Flowers.

Theſe Plants are propagated either from Seeds, or by laying down the tender Branches, which will take Root in one Year's Time, and may then be taken off, and tranſplanted either into a Nurſery, or the Places where they are deſign'd to remain. But if you would propagate them from Seeds, you muſt gather from them the Trees in *January*, (at which Time they commonly are ripe) and preſerve them in Sand until the Beginning of *March*, when you muſt prepare a Bed of light dry Earth, which ſhould be ſituated in a warm Place, where the Plants may be defended from the North and Eaſt Winds: This Bed muſt be levell'd exactly even, and then draw ſome ſmall Furrows croſs it at about eight Inches Diſtance, and an Inch deep, into which you ſhould drop the Seeds, about two Inches aſunder, then cover them with Earth; and if the Seaſon ſhould prove very dry, you muſt often refreſh them with Water. In about two Months Time the young Plants will appear above Ground, when you muſt carefully clear them from Weeds; and in dry Weather if you refreſh them with Water, it will greatly promote their Growth. In theſe Beds they ſhould continue two Years, by which Time they will be large enough to tranſplant; you muſt therefore make choice of a warm dry Spot of Ground, which ſhould be well dug and cleans'd from Weeds and Roots of Trees, *&c.* and laid even; then mark out the Lines three Feet diſtant from each other; and having taken up the Plants carefully with a Ball of Earth to their Roots, you muſt plant them exactly ſtrait in the Rows, at eighteen Inches aſunder, obſerving to water them well, as alſo to lay ſome Mulch upon the Surface of the Ground, near the Stems, to preſerve the Ground from drying too faſt. The beſt Seaſon for removing theſe Trees is in *April*, juſt before they begin to ſhoot.

During the Time theſe Plants remain in the Nurſery, you muſt obſerve to keep them clear from Weeds, digging the Ground between the Rows every Spring; as alſo to faſten the Shoots of the Plants to ſtrait Stakes, to prevent their growing crooked and unſightly; and alſo obſerve to prune off the Under-ſhoots, to make them advance in Height: but I can by no means recommend the ſheering of theſe Plants into conical or pyramidal Figures, (as is the general Practice) for the ſame Reaſon as I gave for the *Laurel, viz.* that the Leaves being large, are cut in Pieces, whereby the Plants are render'd very unſightly; but rather, that they ſhould be improved, ſo as to make large Trees, to which they are naturally diſpos'd to grow, could we prevent the Sheers from continually gnawing them.

Theſe Trees are very proper to plant upon the warm Sides of dry Hills, where they may be protected from the ſevere Blaſts of the North and Eaſt Winds; in which Situations I have ſeen ſome of theſe Trees upward of thirty Feet in Height, which is a plain Indication of their large Growth.

But I know it will be objected, that theſe Trees are often deſtroy'd by hard Winters, and ſo are improper to make large Plantations of in *England*. That they have been ſometimes kill'd by ſevere Winters, I can't deny: but if they are brought up thus hardily, as has been directed, and not ſheer'd, I dare affirm, they will reſiſt the ſevereſt Cold of our Climate, when grown to a moderate Age, provided they are planted in a dry Soil, in which, tho' their Leaves ſhould be intirely ſhrivell'd by extreme Cold, yet, if permitted to remain undiſturb'd, they will ſhoot again in the ſucceeding Summer, as I have more than once experienced. And in the hard Winter, *Anno* 1728. when moſt of the *Bay-Trees* ſeem'd to be deſtroy'd which grew abroad, and many People were ſo inconſiderate as to dig them up, and throw them away, it was obſervable, that all thoſe which were permitted to ſtand, did ſhoot out again in the ſucceeding Summer, and recover'd their uſual Verdure. Which ſhould caution every Perſon, not to be over-haſty in condemning Trees to the Fire, but to wait for the Succeſs of a whole Seaſon, before they are pull'd up.

Bay-Leaves dry'd and reduced to Powder, as much as will cover an Half-Crown, being drank in a Glaſs of White-Wine, are ſaid ſeldom to fail of curing an Ague. Theſe Leaves are alſo uſed in divers Sauces in the Kitchen, and the Berries are often uſed in Medicine.

The Gold-ſtrip'd *Bay* is much more tender than the common Sort; for which Reaſon it muſt be planted in Pots, and houſed in Winter with *Oranges*, *Myrtles*, &c. and muſt be placed ſo as to have as much free Air in mild Weather as poſſible, and will require to be frequently water'd. This Plant may be propagated by Layers, or by budding it upon the common *Bay*: but you muſt not plant it into very rich Earth, which will cauſe it to grow vigorouſly, whereby it will become quite plain; but, on the contrary, let it have a freſh light ſandy Soil, in which it will very well preſerve its beautiful Stripe.

The fourth, fifth, ſixth, ſeventh, eighth, and ninth Sorts are commonly preſerv'd in Pots or Tubs, and placed in the Green-houſe with *Oranges*, *Myrtles*, &c. But I dare ſay; either of theſe Sorts will thrive in the open Air, if planted in a warm dry Soil, and defended from the North and Eaſt Winds; but eſpecially the broad-leav'd Sort, which, I have experienced, will endure more Cold than the common *Bay*: but as they are leſs common, ſo they are generally preſerv'd with more Care; tho' they may either of them be propagated in as great Plenty as the common Sort, either by Layers or Seeds; for they will bear great Plenty of Berries, provided they are not kept ſheer'd; and theſe Berries will riſe full as well, and, many times, out-grow the common *Bay*, as I have frequently obſerv'd: ſo that why we have not theſe Trees in as great Plenty as the common Sort, is only owing to their not being propagated and planted abroad; moſt People imagining, becauſe they have been hitherto treated with great Care, that therefore they will not endure the Cold. Which is a great Miſtake; for we have found, by repeated Trials which have been made within a few Years paſt, that many of thoſe Plants which have been nurs'd up in Green-houſes, with great Care, (whereby their Roots were confin'd, and the Plants circumſcrib'd and ſtarv'd in their Growth) when planted abroad, have made great Progreſs, and defy'd the moſt ſevere Cold of our Climate to injure them: Which is a great Encouragement to proceed in our Trials of this Kind; ſince, by this Method, we may naturalize a great Variety of valuable Trees and Plants to our Country, which may hereafter be found of great Benefit. Nor ſhould we be diſcouraged, if, in the firſt Attempt, we ſhould not ſucceed ſo well as we might wiſh; for, by ſeveral Eſſays, we may overcome the Difficulty; and then the Pleaſure of having denizen'd any Exotick Trees, will ſufficiently compenſate the Trouble, ſince hereby we eſtabliſh living Monuments of Praiſe.

The *Indian Bay* is too tender to endure our cold Winters abroad as yet: tho' I doubt not but that when theſe Plants are very ſtrong and woody, and ſome Care taken in their firſt Expoſure, they may be brought to thrive in the open Air; which, if once obtain'd, ſo as to have Seeds produced in *England*, the Offspring will be better inured to our Climate. And if this Plant can be once well naturalized, ſo as to grow as in the warmer Parts of *Europe*, it will be one of the nobleſt Ever-greens, for Shade and Beauty, we ever obtain'd; for it is naturally a very ſtrait-growing Tree, and the Leaves are very broad, and of a ſhining green Colour, which renders it very agreeable.

This Plant is propagated by Seeds, (which are eaſily procur'd from *Portugal*, where theſe Trees grow in great Plenty); they ſhould be put into Pots fill'd with freſh light Earth, and plung'd into a gentle Hot-bed, to facilitate their Growth; and when the Plants are come up, you ſhould remove the Pots into another moderate Hot-bed, to forward them, where they ſhould remain until the Beginning of *June*, when you muſt harden them by Degrees, to endure the open Air, into which they ſhould be remov'd about the Middle of that Month, obſerving to place the Pots in a well-ſhelter'd Situation; and in dry Weather you muſt often refreſh them with Water. The Beginning of *October* you muſt remove the Pots into the Green-houſe, placing them near the Windows, that the Plants may have as much free Air as poſſible in mild Weather; and obſerve that they do not ſuffer with Drought; for they will require to be frequently refreſh'd with Water. In *April* following, you muſt take the Plants out of the Pots, preſerving the Earth to their Roots, and put each into a ſeparate Pot, fill'd with the before mention'd light freſh Earth: then plunge them into a moderate Hot-bed for a Month or ſix Weeks, to haſten their taking Root; which done, you muſt harden them again, and expoſe them to the open Air, as before: and in Winter they muſt be houſed again, obſerving the Directions before given. After five or ſix Years thus managing them, (ſtill obſerving every Year to let them continue longer out of the Houſe in Autumn, than the preceding) you ſhould in *April* plant ſome of them into the full Ground, in a warm well-ſhelter'd Situation, that they may have good Rooting in the Ground before the Winter comes on: and in Autumn you muſt lay a little Mulch upon the Surface of the Ground, to prevent the Froſt from penetrating to their Roots. But if the Winter following ſhould prove ſevere, you ſhould twiſt a Band of Hay or Straw round their Stems, which will be of great Service to protect them from Cold: and after they have endured two or three Winters abroad, they will be pretty much out of Danger; for tho' a very hard Winter may afterwards kill ſome of their Branches, yet they will ſhoot again the following Summer.

The eleventh and twelfth Sorts were diſcovered by the late Doctor *William Houſtoun*, at *La Vera Cruz*; from whence he ſent the Seeds into *Europe*, which have furniſhed ſome curious Gardens with the Plants. Theſe being Natives of a warm Country, muſt be preſerved in Stoves; otherwiſe they will not live thro' the Winter in this Climate, eſpecially while they are young; but when they have been raiſed to have Strength, they may be kept in a warm Green-houſe, without any Fire. During the Summer Months, they may be placed in the open Air, in a warm ſheltered Situation; but they ſhould not remain too long abroad in Autumn, for if the Froſt ſhould pinch them, they will ſoon decay. In warm Weather, theſe Plants muſt be frequently watered; but in Winter they ſhould have it more ſparingly, unleſs they are kept warm, when they will require a greater Share. As theſe Plants retain their Leaves in Winter, ſo they make an agreeable Variety amongſt other Exotick Plants in the Stove. They may be propagated by Layers, when the Plants are ſtrong enough to ſend forth good Shoots; for as they do not produce Seeds in this Country, ſo it will be difficult to obtain them from abroad. The beſt Time to lay down the Shoots, is in *April*, when you ſhould give them a Hot-bed, which will greatly forward their making of Roots, eſpecially if they are duly watered. But they will not have Roots enough to tranſplant before the next Spring.

LAURUS ALEXANDRINA. *Vide* Ruſcus.

LAURUS TINUS. *Vide* Tinus.

LAWN, is a great Plain in a Park, or a ſpacious Plain adjoining to a noble Seat.

As to the Dimenſions of it, it ſhould be as large as the Ground will permit; but never leſs, if poſſible, than fifty Acres.

As to the Situation of a *Lawn*, it will be beſt to be in the Front of the Houſe, and to lie open to the neighbouring Country, and not pent up with Trees.

If the Houſe front the Eaſt, it will be moſt convenient, becauſe the Rooms will be ſhaded in the Afternoon, and ſo the Objects to be view'd from the Houſe will be much beautify'd by the Sun's ſhining upon them in the Afternoon: for if the beſt Room of the Houſe front the *Lawn*, as it always ſhould do, the Afternoon being the moſt uſual Time for People of Faſhion to ſolace themſelves in ſuch Rooms, then the Afternoon Sun will not be offenſive to thoſe Rooms; nor will the Proſpect be interrupted, but render'd more pleaſant; whereas, were it on the Weſt Side of the Houſe, the Sun, by ſhining from the Object, and directly againſt thoſe Rooms, would by both hinder the Proſpect; and the Generality of Proſpects are moſt pleaſant when the Sun ſhines upon them.

Beſides, there is another Inconveniency; if the *Lawn* be on the Weſt Side of the Houſe, it will give the more way to the Weſt Wind (which is commonly the greateſt) to injure the Houſe, by its having a free Paſſage to it.

If the *Lawn* be on the South Side of the Houſe, it may do well enough, for the Reaſons before mention'd; for the Sun's Rays being then darted obliquely, will not much interrupt the Proſpect; and the Sun ſhining moſt part of the Day on that Side of the Houſe, will ſtill add to the Beauty of that Front, which ought to be the beſt Front in the Houſe; therefore a *Lawn* on that Side will much help the Proſpect of the Houſe.

It will not be at all convenient to have the *Lawn* on the North Side of the Houſe, becauſe it will lay the Houſe too open to the cold North Winds, *&c.* therefore it will be more eligible to plant Wilderneſſes and Woods on the Weſt and North Sides of the Houſe.

If the Figure of the Houſe be built in this Form ⌶, or any other, the Front may be on both Sides of the Houſe alike, making an Angle at the Middle of the Front, or at ſome Court-Gate right before it, and breaking off at a convenient Diſtance from the Houſe.

As to the Figure of a *Lawn*, the Square is a very proper one, and if it be bounded with Walks, it may not be much amiſs; tho' I rather recommend an open *Lawn*; but if Perſons chuſe to have it bounded, a ſingle Row of Lime-Trees, ſet at a good Diſtance one from another, will not look amiſs, and being ſo placed, they will the better ſhew the Shape of their Heads; but however, the Front of the *Lawn* ſhould be left open, except the *Lawn* fall very much from the Houſe.

If Perſons will, there may be three Avenues breaking out at three Angles; or one at the Angle oppoſite to the Houſe; and if the *Lawn* be a riſing Ground to the Houſe, ſome Trees ſet thin upon it will not look unpleaſant. If the *Lawn* be a Circle, it may not be amiſs; but then it ought to break off before it comes againſt the Front.

Neither is a Triangle a very improper Figure for a *Lawn*, but if ſo, the Angle which leads to the Front muſt not be too acute; but it ſhould rather be obtuſe or right-angled, at the Angle that is next to the Front.

If the *Lawn* be bounded with Trees, Lime-Trees are very proper for that Purpoſe, becauſe they are Trees that will grow well in any Soil, if Care be taken in the Planting of them; and beſides that, all the Trees will grow in a very fine Shape, appearing as tho' they were cut, if they are not too thick planted, and you will have a Proſpect of the adjoining Country between their Stems, eſpecially if their Heads are pruned up to a reaſonable Height; but if that Part of the Country upon which you look is not agreeable, then you ſhould bound the View with a riſing Plantation of Trees, form'd into an Amphitheatre, which will be very agreeable.

The *Elm* is a very proper Tree for planting of *Lawns*, having a fine green Leaf, and if the Ground be natural to it, it will grow to a large Tree and ſtrait, if it be ſtill kept pruned as it ought to be.

The *Beech* makes a ſtately Tree, where it likes the Ground, alſo the *Cheſnut*, the *Walnut* and the *Black-Cherry* Tree; for where they like the Ground, they are not only quick Growers, but repreſent a very delightful Scene in the Spring, when cloath'd in their white Attire.

Firs and *Pines* do very well, if the Ground be ſuitable to them, and theſe being always green, afford a conſtant Pleaſure both in Winter and Summer.

LAYERS: Many Trees may be propagated by *Layers*, the Ever-greens about *Bartholomew-tide*, and other Trees about the Month of *February*.

This is to be perform'd by ſlitting the Branches a little way, and laying them under the Mould about half a Foot: the Ground ſhould firſt be made very light, and after they are laid, they ſhould have a little Water given them.

If they do not comply well in the laying of them down, they muſt be pegg'd down with a Hook or two, and if they have taken ſufficient Root by the next Winter, they muſt be cut off from the main Plants, and planted in the Seminary, as is directed about Seedlings.

Some twiſt the Branch or bare the Rind, and if it be out of the Reach of the Ground, the faſten a Tub or Baſket near the Branch, which they fill with good Mould, and lay the Branch in it.

Laying of Trees.

This Operation is thus perform'd.

1ſt, Take ſome of the Boughs and lay them into the Ground about half a Foot deep in fine freſh Mould, leaving them with the End of the *Layer* about a Foot, or a Foot and a half out of the Ground, and keep them moiſt during the Summer Seaſon; and they will probably have taken, and be fit to remove: and if they have not by that Time taken Root, they muſt lie longer.

2dly, Tie a Piece of Wire hard round the Bark of the Bough, at the Place you intend to lay in the Ground, and twiſt the Ends of the Wire, ſo that they may not untie, and prick the Place above the Wire thro' the Bark with an Awl in ſeveral Places, and then lay it into the Ground, as before directed.

3dly, Cut a Slit upwards at a Joint, as is practiſed in laying of *Carnations*, which by Gardeners is call'd *Tonguing the Layers*.

4thly, Twiſt the Place that you deſign to lay in the Ground like a Withy, and lay it into the Ground as directed in the firſt Way of Laying.

5thly, Cut a Place round about the Bough (that is deſign'd to be laid) an Inch or two, at the Place that is moſt convenient to lay into the Ground, and manage it as is directed in the firſt Method of Laying.

The Seaſon for laying Hardy Trees that ſhed their Leaves, is in *October*; but for ſuch as are tender, in *March*; for Evergreens, *June* or *Auguſt* are good Seaſons.

Tho' *Layers* may be laid at any Time in the Year, yet thoſe Seaſons before-mention'd are moſt proper, for the Reaſons following; becauſe they have the whole Winter and Summer to prepare and draw Root; for at theſe Times of the Year the Sun has ſufficient Power on the *Sap* of the Tree to feed the *Leaf* and *Bud*, but has not Power ſufficient to make a Shoot.

And if that ſmall Quantity of Sap that does ariſe be hinder'd, as it will by ſome of the preceding Ways of *Laying*, the *Leaves* and *Buds* will gently crave of the *Layer*, and by that means will prepare the *Layer* to take Root, or put forth Roots a little to maintain itſelf, finding it cannot have it from the Mother-Plant.

And therefore, becauſe it wants but little Nouriſhment at that Time of the Year, it is better to lay *Layers* of Trees, or to ſet *Cuttings*, than at other Times, either in the Winter, when the Sap ſtirs but little, or in the Summer, when the Sap abounds, or in the Spring, when it begins to riſe; becauſe it is then apt to come too ſuddenly to draw Sap from the *Layer* before the *Layer* has drawn or prepar'd for Root.

However, the Spring or Summer may do well for ſmall Plants; becauſe ſuch Plants being but ſhort-liv'd, draw Root the quicker.

If you would lay young Trees from an high Standard, the Boughs of which cannot be bent down to the Ground, then you muſt make uſe of Ozier-Baſkets, Boxes, or Pots, fill'd with fine ſifted Mould, mix'd with a little rotten Willow-Duſt, which will keep Moiſture to aſſiſt the *Layer* in taking Root: This Baſket, Pot, &c. muſt be ſet upon a Poſt or Treſſel, &c. and the Bough muſt be laid according to either of the four firſt Ways of Laying; but too much Head muſt not be left on, leſt that be injur'd by the Wind, or by its own Motion rub off the tender Root; and the ſmaller the Boughs are, the leſs Way they ſhould be ſet out of the Ground, and Care muſt be taken to keep them clear from Weeds.

The harder the Wood is, the better will the young Wood take Root; but if the Wood be ſoft, the older Boughs will take Root the beſt.

LEAVES, are defin'd to be a Part of a Plant extended into Length and Breadth, in ſuch a Manner as to have one Side diſtinguiſhable from the other; they are properly the moſt extreme Part of a Branch, and the Ornament of the Twigs, and conſiſt of a very glutinous Matter, being furniſh'd every where with Veins and Nerves; one of their Offices is, to ſubtilize and give more Spirit to the Abundance of nouriſhing Sap, and to convey it to the little Buds.

A *Simple Leaf* is that which is not divided to the Middle.

A *Compound Leaf*, is divided into ſeveral Parts, each reſembling a ſimple *Leaf*, as in *Liquorice*, &c.

A *Digitated Leaf*, is a compound *Leaf* divided into ſeveral Parts, all of which meet together at the Tail, as in the *Hemp*, *Black Hellebore*, &c.

A *Trifoliated Leaf*, is a digitated *Leaf*, conſiſting of three Fingers, as the *Trefoil*, &c.

A *Quinquefoliated Leaf*, is a digitated *Leaf*, conſiſting of five Fingers, as in the *Quinquefolium*.

A *Pennated Leaf*, is a compound *Leaf* divided into ſeveral Parts, (each of which is call'd a *Lobe*) placed along the middle Rib, either alternately, or by Pairs. When the middle Rib is terminated by an odd *Lobe*, it is ſaid to be *unequally Pennated*, as in the *Goats Rue*, &c. and *equally Pennated*, when it is not terminated by an *odd Lobe*, as in the *Caſſia*; when the Lobes are all nearly of the ſame Form and Bigneſs, it is call'd an *uniform pennated Leaf*, as in the *Liquorice*; when they are not ſo, it is ſaid to be *Diſform*, as in the *Agrimonia*.

A *Winged Leaf*, is, as it were, divided into ſeveral *pennated Leaves*, as in the *Orobus*, &c.

A *Ramoſe Leaf*, is that which is ſtill farther divided than the *winged Leaf*, as in the *Oſmund Royal*, *Female Fern*, &c.

An *Intire Leaf* or *Lobe*, is that which has no Diviſion on its Edges, as in the *Apple-tree*, &c.

A *Sinuated Leaf*, is that which is cut about the Edges into ſeveral long Segments, as in *common Mallow*.

A *Serrated Leaf*, is that which is cut about the Edges into ſeveral *acute Segments*, reſembling the Teeth of a *Saw*, as in the *Nettle*, &c.

A *Crenated Leaf*, is that which is cut about the Edges into ſeveral *obtuſe Segments*, as in the *Betony*, &c.

A *Laciniated* or *Jagged Leaf*, is that which is cut about the Edges into ſeveral pretty deep Portions, in an irregular Manner, as in the *Horned Poppy*, &c.

Leaves are a Part of a Plant that is ordinarily very thin and flat, growing in the Spring, and falling off at the Autumn; tho' there are ſome Plants without *Leaves*, as the *Truffles* and *Muſhrooms*.

As to the Structures of *Leaves*, Dr. *Grew* obſerves, That their Fibres never ſtand on the Stalk in an even Line, but always in an angular or circular Poſture; and the Vaſcular Fibres or Threads are three, five, or ſeven: the Reaſon of which Poſition, is for the more erect Growth and greater Strength of the *Leaf*.

Another Obſervable in the Fibres of *Leaves*, is, their orderly Poſition, ſo as to take in an Eighth Part of a Circle, as in *Mallows*; in ſome a Tenth, and in moſt a Twelfth Part.

Dr. *Grew* alſo obſerves ſix ſeveral Parts intended by Nature for the Preſervation of *Gems*, viz. *Leaves*, Sunfoils, Interfoils, Stalks of *Leaves*, Hoods, and Mantlings, that cover them.

The Skin or Coat of the *Leaves*, is no more than that of their Branches extended; as Gold, by beating, is reduced to Leaves: in the Gem they are folded, and ſometimes in ſeveral Plaits, ſomewhat after the Manner of a Fan. If the *Leaves* are too thick to plait commodiouſly in two, and to be rang'd againſt each other, or if they be in too ſmall a Number, and their Fibres too delicate; inſtead of being plaited, they are roll'd up, and form either a ſingle Roll, as the *Leaves* of the *Mountain Cowſlip*, which are thick, or two Rolls, which begin at each Extremity of the *Leaf*, and meet in the Middle.

There are ſome Plants whoſe *Leaves* form three Rolls, as *Fern*, &c. Several *Leaves* are cover'd with Hair of ſeveral Figures; thoſe of *Lavender* and the *Wild Olive-Tree* have Hairs reſembling Stars.

The Uſe of *Leaves*, is to cover the Flowers and Fruits with their Shade, and to keep them from other Inconveniences; and they ſerve alſo for Ornament, to make the Tree look pleaſant to the ſight, and are to Trees, as Hair is to Human Bodies.

Some compare the *Leaves* of Plants, that firſt explain themſelves, to the *Placenta* in Animals, and are as the Coats of the little Buds.

The Foot-ſtalks of the *Leaves*, by which the nouriſhing Sap is convey'd to them, and divides itſelf into the Sinuoſities or Circuits, which are found throughout the whole Structure; by means of which, the nouriſhing Juice is refin'd, and, in part, may receive the moſt ſpirituous Particles of the Air.

Some have obſerved, that if the *Leaves* that are adjoining to the Bud are deſtroy'd, it will ſhoot no more, till freſh *Leaves* come forth again to ſuccour it; for, in this Caſe, the *Leaves* do the ſame Office which the *Ear-leaves* do to the *Gem* in its firſt State of Vegetation.

Botaniſts conſider the *Leaves* of Plants, with regard to their Structure, to their Surface, Figure, Conſiſtence, their Edges, Situation, and Size.

With regard to their *Structure*; *Leaves* are either ſingle, as the *Apple-tree*, *Pear-tree*, &c. or double, as thoſe of *Angelica*, *Parſley*, &c.

With regard to their *Surface*; *Leaves* are either flat, as the *Nummularia*, *Aſarum*, *Origany*, *Androſæmum*, &c. or hollow, as thoſe of the *Onion* or *Aſphodelus*; or in Bunches, as ſeveral Kinds of *Kali* and *Houſeleeks*.

With regard to their *Conſiſtence*; *Leaves* are either thin and fine, as thoſe of *St. John's-wort*, &c. or thick and groſs, as thoſe of *Portulaca*; or fleſhy, as thoſe of ſeveral Kinds of *Houſeleeks*; or woolly, as thoſe of the *Gnaphalium*, &c.

With regard to their *Edges*; *Leaves* are either cut ſlightly, as ſome Species of *Geums*; or deep, as in ſome of the *Jacea's*.

With regard to their *Situation*; *Leaves* are either alternate, that is, ranged alternately, as the *Alaternus*; or oppoſite to each other, as the *Phillyrea*, and the *Mints*.

With regard to their *Size*; *Leaves* are either very big, as thoſe of the *Collocaſia* and *Sphondylium*; or moderate, as thoſe of *Biſtort*, the *Fig-tree*; or ſmall, as thoſe of the *Apple-tree* and *Pear-tree*; or very ſmall, as that of *St. John's-wort*.

Moſt Sorts of ſmall Plants, and alſo ſeveral Sorts of Trees, which put forth a Root at the ſmall End of the Seed, as ſoon as that Root has taken hold of the Ground, they put out two ſmall Leaves above Ground, which are not at all like to thoſe that grow on the Plant or Tree, which two falſe Leaves are the Seed, which divides itſelf into two Parts, and ſo remains ſome ſhort Time on the Top of the Ground, and afterwards between thoſe two *falſe Leaves* comes forth a Shoot, which produces *Leaves* like thoſe of the Plant or Tree from whence it came.

Of this Manner of Growth there is an infinite Number of Plants and Trees, as *Angelica*, *Carduus*, *Carrots*, *Melons*, *Parſnips*, *French-Beans*, and indeed moſt Sorts of Seeds: and as to Trees, the *Apple*, the *Aſh*, the *Elm*, the *Maple*, the *Pear*, the *Quince*, the *Sycamore*; and moſt Sorts of Seeds of Trees which are not inviron'd by Stones or Shells.

Leaves is a Term uſed to expreſs the moſt ſenſible and agreeable Parts of Flowers.

It is true, all Flowers have not *Leaves*; and it is difficult to determine, which is to be call'd *Leaves*, and which the *Calyx*, of the ſame Flower.

To prevent the confounding the *Leaves* of the Flowers with the reſt of the Plant, thoſe of the Flower are call'd *Petala*, from a *Greek* Word which the *Botaniſts* have adopted into their *Latin* Deſcriptions, when they ſpeak of the Leaves of Flowers; the *Leaves* of Flowers, they call *Petala*; and thoſe of Plants, *Folia*.

Dr. *Grew* obſerves, That the Fibres of *Leaves* are compoſed of the two general Kinds of Veſſels, *viz.* for *Sap* and *Air*, and are ramify'd out of greater into leſs, as Veins and Arteries are in Animals.

And ſome are ſaid to be of Opinion, that the Veſſels in the *Leaves* of Plants are muſculated, not Side to Side, but the Ends of ſome into the Sides of others. Yet this is not really done, the ſmaller Threads being ſo far deducted, as ſometimes to ſtand at Right Angles with the larger; ſo that they are muſculated only End to End, or Mouth to Mouth, after they are at laſt come to their final Diſſolution.

Dr. *Agricola* gives Directions for raiſing Trees from *Leaves*; to whoſe Treatiſe I ſhall refer thoſe who have a mind to try the Experiment. I ſhall only ſay, that I myſelf have had the *Leaves* of *Cabbages*, *Lauruſtins*, and ſome other Plants, ſtrike out Roots when laid in the Earth, and have alſo raiſed ſeveral Sorts of *Aloes*, by planting their *Leaves*, which have ſhot out young Plants from their under Parts.

Some have made this Obſervation, that thoſe Trees that hold their *Leaves*, have their Wood cloſe and compact between their annual Circles; and the Reaſon that they hold their *Leaves* all the Winter is, that their Sap is of a clammy and turpentine Subſtance: and the Sap of ſuch Trees as hold their *Leaves*, being once ſet by Cold, requires a great deal of Heat to make it thin, and put it into Motion; as, comparatively, a little Cold will ſet or ſtiffen Pitch or Turpentine, but it muſt be Froſt that ſets or ſtays the Motion of Water.

Thoſe Trees which hold their *Leaves*, will grow much better under the Dropping of other great Trees, than ſuch as ſhed their *Leaves*; becauſe their Turpentine Sap ſhoots off the Drops: and as for thoſe Trees that ſhed their *Leaves*, their Sap aſcends in a ſmall Quantity between the annual Circles in the porous Place: This, they ſay, may be obſerv'd in a Tree that is bark'd round; for that Tree will put forth *Leaves*, and increaſe in Body, but produce little or no Shoot; and the more porous the Tree is between thoſe annual Circles, the longer that Tree will live, as hath been experienced in *Walnut-trees*, *Aſh-trees*, &c.

Naturaliſts aſcribe to *Leaves* a four-fold Uſe:

1. Chiefly, that they do in the Spring-time receive the crude Humours into themſelves, divide them very minutely, and move them ſtrongly in the Utricles, and perhaps draw in from the Air what is neceſſary, tho' unknown to us, and carry back great Plenty of elaborated Juice to the Plant.

2. That there may be a Tranſpiration of what is unprofitable, anſwering to the Diſcharge made by Sweat; for ſometimes thoſe excretory Veſſels of the *Leaves* are ſo overcharged by the great Plenty of diſtending Humour [Juice] that they burſt in the Middle, and let go the more ſubtile Parts: nor is it ſeldom, that in a hot Seaſon great Plenty of Juices are this Way diſcharged and imbibed. Thus *Manna* is found to exſude [ſweat forth] as well from the *Leaves* as from the *Bark*, if a cold Night ſhall follow a hot Day: and the ſame thing frequently happens in divers other Plants and Trees; as we learn from the Bees flying to the *Lime-tree*, that they may gather hat gummous Subſtance from their Leaves: but if the Heat ſhall be leſs, all the ſuperfluous Humours (except thoſe which, perhaps, are tranſmitted by inſenſible Tranſpiration thro' the arterial Veſſels exhaling naturally) are ſeen to return into the Trunk.

3. That the bibulous Veſſels dried by the diurnal Heat, and for this Reaſon to be compared to Veins, may imbibe, in the Night-time eſpecially, thoſe watery Parts, which, among others, lie hid in the Air under the Form of a very thin Dew, and ſo make amends for the Loſs made by the Arteries, by the new Moiſtures receiv'd.

4. Laſtly, the *Leaf* ſerves chiefly for this Purpoſe, that it may keep and nouriſh the Eye or Gem, until the Gem by degrees growing out to a greater Bulk, preſſes together the Veſſels of the Foot-ſtalk, from whence the Humour is by little and little ſtopp'd in the *Leaf*, till it cannot any more return to the Foot-ſtalk; which, by the ceaſing of the Afflux and Reflux of the nutritious Juice, grows putrid, whence a Conſumption being cauſed, the *Leaf* dies and falls off, which is the chief Cauſe of the falling of the *Leaves* in Autumn.

The Rev. Dr. *Hales*, in his excellent Treatiſe of *Vegetable Staticks*, ſpeaking of the Perſpiration of *Plants*, gives an account of the following Experiments; *viz.*

That in *July* or *Auguſt* he cut off ſeveral Branches of *Apple-trees*, *Cherry-trees*, *Pear-trees*, and *Apricock-trees*, two of a Sort; they were of ſeveral Sizes, from three to ſix Feet long, with proportional lateral Branches; and the tranſverſe Cut of the largeſt Part of the Stems was about an Inch Diameter.

That he ſtripp'd off the *Leaves* of one Bough of each Sort, and then ſet their Stems in ſeveral Glaſſes, pouring in known Quantities of Water.

The *Boughs* with *Leaves* on them imbibed ſome fifteen Ounces, ſome twenty, twenty-five or thirty in twelve Hours Day, more or leſs, in Proportion to the Quantity of *Leaves* they had; and when he weigh'd them at Night, they were lighter than in the Morning.

While thoſe without *Leaves* imbibed but one Ounce, and were heavier in the Evening than in the Morning, they having perſpir'd little.

The Quantity imbib'd by thoſe with *Leaves* decreas'd very much every Day, the Sap-veſſels being probably ſhrunk at the tranſverſe Cut, and too much ſaturate with Water to let any more paſs; ſo that uſually in four or five Days the *Leaves* faded and wither'd much.

He adds, that he repeated the ſame Experiment with *Elm-branches*, *Oak*, *Oſier*, *Willow*, *Sallow*, *Aſpen*, *Curran*, *Gooſberry*, and *Philbert* Branches; but none of theſe imbib'd ſo much as the foregoing, and ſeveral Sorts of Ever-greens very much leſs.

He adds alſo another Experiment: That on the 15th of *Auguſt*, he cut off a large *Pippen* with two Inches Stem, and its twelve adjoining *Leaves*; that he ſet the Stem in a little Phial of Water, and it imbib'd and perſpir'd in three Days One-third of an Ounce.

And that at the ſame time he cut off from the ſame Tree another bearing Twig of the ſame Length, with twelve *Leaves*, no Apple on it, and it imbib'd in the ſame three Days near Three-fourths of an Ounce.

That about the ſame time, he ſet in a Phial of Water a ſhort Stem of the ſame Tree, with two large Apples on it, without *Leaves*, and they imbib'd near Three-fourths of an Ounce in two Days.

So in this Experiment, the *Apples* and *Leaves* imbibed Four-fifths of an Ounce; the *Leaves* alone near Three-fifths; but the two large *Apples* imbib'd and perſpir'd but One-third Part ſo much as the twelve *Leaves*; then the one *Apple* imbib'd the One-ſixth Part of what was imbib'd by the twelve Leaves: therefore two *Leaves* imbibe and perſpire as much as one *Apple*: whence their Perſpirations ſeem to be proportionable to their Surfaces; the Surface of the *Apple* being nearly equal to the Sum of the upper and under Surfaces of the two *Leaves*.

Whence it is probable, that the Uſe of theſe *Leaves* (which are placed juſt where the Fruit joins to the Tree) is to bring Nouriſhment to the Fruit.

And accordingly he obſerves, that the *Leaves* next adjoining to the Bloſſoms, are in the Spring very much expanded, when the other *Leaves* on barren Shoots are but beginning to ſhoot; and that all *Peach Leaves* are very large before the Bloſſom goes off.

And that in *Apples* and *Pears*, the *Leaves* are one third or half grown before the Bloſſom opens; ſo provident is Nature in making timely Proviſion for the nouriſhing the yet Embryo Fruit.

He alſo adds another Experiment: He ſtripp'd the *Leaves* of an *Apple-tree* Branch, and then fix'd the great End of the Stem in the Gage; it rais'd the Mercury $2 + \frac{1}{2}$ Inches, but it ſoon ſubſided, for want of the plentiful Perſpiration of the *Leaves*, ſo that the Air came in almoſt as faſt as the Branch imbib'd Water.

And as a farther Proof of the Influence of the *Leaves* in raiſing the Sap, he alſo made the following Experiment:

On the 6th of *Auguſt*, he cut off a large *Ruſſet Pippin*, with a Stalk $1 + \frac{1}{2}$ Inch long, and twelve adjoining *Leaves* growing to it.

He cemented the Stalk faſt in the upper End of a Tube; which Tube was ſix Inches long, and one fourth Diameter: as the Stalk imbib'd the Water, it rais'd the Mercury four Inches high.

That he fix'd another *Apple* of the ſame Size in the ſame Manner, but firſt pull'd off the *Leaves*, and it rais'd the *Mercury* but one Inch: That in the ſame Manner he fix'd a like-bearing Twig, with twelve *Leaves* on it, but no *Apple*, and it rais'd the *Mercury* three Inches.

He then took a like-bearing Twig, without either *Leaves* or *Apple*, and it rais'd the *Mercury* One-fourth of an Inch.

So a Twig, with an *Apple* and *Leaves*, rais'd the *Mercury* four Inches; one with *Leaves*, only three Inches; one with an *Apple* without *Leaves*, only one Inch.

A *Quince*, which had two *Leaves* juſt at the Twig's Inſertion, rais'd the *Mercury* $2 + \frac{1}{2}$ Inches, and held it up a conſiderable time.

A Sprig of *Mint* fix'd in the ſame Manner, rais'd the *Mercury* $3 + \frac{1}{2}$ Inches, = to four Feet five Inches Height of Water.

Theſe and many more Experiments of the Rev. Dr. *Hale*, that curious Inquirer into the Cauſes, State, and Progreſs of Vegetation, evidently ſhew the great Perſpiration of the *Leaves* of Plants, and their great Uſe in raiſing the Sap, and other Functions of Vegetable Nature: To whoſe excellent Treatiſe before-mention'd, I refer the curious Enquirer.

I ſhall add, that Nature has directed us as to the true Diſtance we ought to train the Branches of Trees againſt Walls or Eſpaliers, which ſhould always be in Proportion to their *Leaves*; for if we obſerve the Progreſs of Nature in the great Variety of Trees, we ſhall always find their Branches grow diſtant from each other in proportion to the Breadth of their *Leaves*: And it was upon this Account that the *Romans* ſo much admir'd the *Platanus*, becauſe the *Leaves* being large, afforded them a kindly Shade in Summer; but in Winter, when they are deſtitute of *Leaves*, their Branches growing at a great Diſtance, eaſily admitted the Beams of the Sun.

Some there are who aſſert, that by the *Leaves* of each aſpiring Plant, a Perſon may diſtinguiſh each Kind of Fruit, whether delicate or harſh, that the Hopefulneſs of the Fruit may be diſtinguiſh'd by the firſt *Leaves* of the yearling Plant; and for this they lay down the following Rules:

1ſt, That a ſhort and dark Green *Leaf* prognoſticates a crabbed Fruit.

2dly, That a Tree with a larger *Leaf*, thick, and of a dark Green, will bear a good Winter *Apple*; but the Stock hardy, to endure a ſtiff clayey Ground.

3dly, That a fady willowiſh *Leaf*, denotes a flat inſipid *Apple*, as the *Kentiſh Codlin*, which holds out againſt Blaſts.

4thly, That a paler Green, as the *Popinſay* or *Barbary Leaf*, eſpecially if the *Leaf* be limber, denotes a delicate Fruit; and the broader the *Leaf* is, the fairer the Fruit.

5thly, That a wrinkled *Leaf*, neither very dark, nor very bright, proves Red-ſtreak'd: *Crab-ſtocks* have reddiſh Tops.

But there is no great Certainty in theſe Rules, nor can a Perſon, tho' ever ſo curious in his Obſervations, exactly determine the various Sorts of Fruits by their *Leaves*, notwithſtanding what many People have aſſerted.

The before-mention'd Reverend Author, in his Treatiſe of *Vegetation*, ſays, It is plain from many Experiments and Obſervations before-mention'd, that *Leaves* are very ſerviceable in this Work of *Vegetation*, by being inſtrumental in bringing Nouriſhment from the lower Parts, within the Reach of the Attraction of the growing Fruit, which, like young Animals, is furniſh'd with proper Inſtruments to ſuck it thence; but the *Leaves* ſeem alſo deſign'd for many other noble and important Services: for Nature admirably adapts her Inſtruments, ſo as to be at the ſame Time ſerviceable to many good Purpoſes.

Thus the *Leaves*, in which are the many Excretory Ducts in Vegetables, ſeparate and carry off the redundant watery Fluid, which by being long detain'd, would turn rancid and prejudicial to the Plant, leaving the more nutritive Parts to coaleſce; Part of which Nouriſhment, we have good Reaſon to think, is convey'd into Vegetables thro' the *Leaves*, which do plentifully imbibe the Dew and Rain, which contain Salt, Sulphur, *&c.*

For the Air is full of acid and ſulphureous Particles; which, when they abound much, do, by the Action and Reaction between them and the elaſtick Air, cauſe that ſultry Heat which uſually ends in Lightning and Thunder; and theſe new Combinations of Air, Sulphur, and acid Spirit, which are conſtantly forming in the Air, are, doubtleſs, very ſerviceable in promoting the Work of Vegetation; when being imbib'd by the *Leaves*, they may not improbably be the Materials out of which the more ſubtile and refined Principles of Vegetables are form'd: For ſo fine a Fluid as the Air ſeems to be a more proper Medium, wherein to prepare and combine the more exalted Principles of Vegetables, than the groſſer watery Fluid of the Sap: And, for the ſame Reaſon, it is likely that the moſt refined and active Principles of Animals are alſo prepared in the Air, and thence convey'd thro' the Lungs into the Blood; and that there is Plenty of theſe ſulphureo-aërial Particles in the *Leaves*, is evident from the ſulphureous Exudations that are found in the Edges of *Leaves*, of which Bees are obſerv'd to make their waxen Cells, as well as of the Duſt of Flowers. And that Wax abounds with Sulphur, is plain, from its burning freely, *&c.*

We may therefore reaſonably conclude, that one great Uſe of *Leaves*, is what has been long ſuſpected by many, *viz.* to perform, in ſome meaſure, the ſame Office for the Support of the Vegetable Life, as the Lungs of Animals do for the Support of Animal Life; Plants, very probably, drawing thro' their Leaves ſome Part of their Nouriſhment thro' the Air.

LEEKS. *Vide* Porrum.

LEGUMES *or* LEGUMENS, are a Species of Plants which are call'd *Pulſe*, ſuch as *Peas*, *Beans*, &c. and are ſo call'd becauſe they may be gather'd by the Hand, without cutting. Mr. *Ray* reckons all thoſe Plants which have a papilionaceous Flower, among the *Legumes*.

LEGUMINOUS, of or belonging to *Pulſe*.

LEGUMINOUS PLANTS, are ſuch as bear *Pulſe*, with a papilionaceous Flower: Their Flower is difform, and ſomewhat like a *Butterfly*, with Wings expanded, (whence it is call'd Papilionaceous) conſiſting of four Parts, join'd together at the Bottom. *Vide* Papilionaceous.

LEMON-TREE. *Vide* Limon.

LENS, [ſo call'd of *Lenis*, Lat. *mild* or *gentle*, becauſe in old Times, thoſe who eat theſe Seeds, were ſaid to be of a gentle Temper] Lentils.

The *Characters* are;

It hath a papilionaceous Flower; the Pointal of which becomes a ſhort Pod, containing orbicular Seeds, which are, for the moſt part, convex: To which may be added, the Leaves are conjugated, growing to one Mid-rib, and are terminated by Tendrils.

The *Species* are;

1. Lens *vulgaris*. *C. B. P.* Common Lentils.
2. Lens *major*. *C. B. P.* Greater Lentils.
3. Lens *monanthos*. *H. L.* Lentils with a ſingle Flower.

There are ſeveral Varieties of the firſt and ſecond Sorts, which differ from each other in the Colour of their Flowers and Fruits; but theſe are accidental, and will often riſe from the ſame Seeds; for which Reaſon they are not worth obſerving in this Place.

Theſe Plants are very common in the warm Parts of *Europe*, and in the *Archipelago*, where they are the Food of the poorer Sort of People, which they loath when they meet with better Fare; from whence came the Proverb, *Dives factus jam deſiit gaudere Lente:* Which is apply'd to ſuch as ſpurn at thoſe Things in eaſy Circumſtances, which they were glad of in a low Condition.

Theſe Plants are one of the leaſt of the *Pulſe* Kind, and call'd in ſome Places *Tills:* They may be propagated in the ſame Manner as *Vetches*, &c. but muſt be ſown a great deal thinner. They will grow upon a dry barren Soil beſt, and are a very good Fodder for Cattle; but as they require an annual Culture, ſo they are not at preſent very much eſteem'd. Their Seeds are very good for Pigeons.

LENS PALUSTRIS, Duck-Meat. This is a very common Plant, growing upon ſtanding Waters in moſt Parts of *England*.

LENTISCUS, [takes its Name of *Lentor*, Lat. *i. e. Pliableneſs*] The Maſtick-Tree.

The *Characters* are;

The Leaves are pinnated; the Lobes growing oppoſite, and are faſten'd to one common Mid-rib; the Male Flowers, which are produced upon ſeparate Trees from the Fruit, have ſhort green quadrifid Cups, which expand in Form of Stars, having four or five ſhort Stamina, with large red Apices: Theſe Flowers are collected into a Bunch: The Ovary, in the Female Plants, which grows upon the Top of a long thick Foot-ſtalk, is commonly branched, and becomes a Fruit, which contains a Nut with a hard Shell.

The *Species* are;

1. Lentiscus *vulgaris*. *C. B. P.* Common Maſtick-Tree.
2. Lentiscus *vulgaris*, *foliis minoribus & pallidioribus*. *H. L.* The Male Maſtick-Tree, with leſſer and paler Leaves.

Theſe two Plants are promiſcuouſly preſerv'd in many curious Gardens in *England*, where they are commonly kept in Pots and Tubs, and houſed in the Winter, with *Oranges*, *Myrtles*, &c. but in ſome Places, which are well defended from cold Winds, I have obſerv'd them growing in the open Air, without ſuffering the leaſt Injury from our ordinary Winters; but in extreme hard Weather, they are ſometimes greatly damaged; however, as they are ſeldom quite deſtroy'd, eſpecially if the Plants are ſtrong, and have taken good Root in the Ground, ſo it is worth our Care to endeavour to naturalize them to our Climate; which may eaſily be effected, provided you keep them in Pots until they have acquired a ſufficient Strength, and then ſhake them out in the Spring of the Year, preſerving as much of the Earth to their Roots as you can, planting them on a dry warm Soil, and in a well-ſhelter'd Situation; and in Winter lay ſome Mulch upon the Surface of the Ground about their Roots, to prevent the Froſt from penetrating to them, as alſo in very ſevere Froſts you ſhould cover their Stems and Heads with ſome Straw or Peas-haulm, which will prevent their being deſtroy'd; and after they have been inured to the open Air for two or three Years, they will then be moſtly out of Danger, and will grow much better than thoſe Plants which are kept in Pots or Tubs.

Theſe Plants are propagated by laying down their young Branches in the Spring, which ſhould be ſlit at a Joint, (as is practiſed in laying *Carnations*) and in dry Weather they muſt be frequently water'd, to encourage their ſtriking Root, which they rarely do until the ſecond Year, before which they ſhould not be diſturb'd; but then if they have taken ſufficient Root, they ſhould be tranſplanted in *April*, placing them, as was before directed, into a warm Situation, obſerving to water them in dry Weather, as alſo to lay ſome Mulch about their Roots, to prevent the Ground from drying too faſt; and in Winter lay a little freſh Mulch about them, to keep out the Froſt; after two or three Years, they will be ſufficiently hardy, and will require no farther Care, but to dig the Ground about them every Spring, and keep them clean from Weeds, as alſo to trim up the lateral Branches, to make them aſpire in Height; but by no means ſhould you ſheer them into Balls and Pyramids, (as is the common Practice) but let them grow in their utmoſt Luxuriancy, in which Manner they will appear much more beautiful than in thoſe ſtudied Figures.

Theſe Plants may alſo be propagated from the Berries, which may be obtain'd from the ſouthern Parts of *France* or *Spain*, where they grow in great Plenty; they muſt be ſown in Pots or Tubs of light freſh Earth, and houſed in Winter; (for the Plants ſeldom come up until the ſecond Year) but in Summer they ſhould be expoſed in a warm Situation, and often refreſh'd with Water; when the Plants come up, they muſt be carefully clear'd from Weeds, and refreſh'd with Water in dry Weather; and in Winter the Pots or Tubs muſt be removed into Shelter, but ſhould have a great Share of free Air in mild Weather; and the Spring following, the Plants ſhould be taken up, and each of them planted into a ſeparate Pot; then plunge the Pots into a moderate Hot-bed, to facilitate their taking Root, after which they may be expoſed to the open Air, (as was directed for the older Plants) and continue to houſe them every Winter, until they are three or four Years old, after which they may be planted into the open Air, when they muſt be treated as the old Plants.

Theſe Trees are always green, which renders them more valuable, and their Leaves being of a beautiful Figure, and their Heads generally growing very regular, renders them worthy of a good Situation; they ſeldom riſe above twelve or fourteen Feet high with us, and ſhould therefore be intermix'd with other Ever-greens of the ſame Growth.

LEONTOPETALON, [Λεοντοπέταλον, of λέων, *a Lion*, and πέταλον, *a Leaf*, q. d. *Lion's-Leaf*; becauſe the Antients fancied the Leaves of this Plant reſembled a Lion's Paw] Lion-Leaf.

The *Characters* are;

It hath a thick tuberoſe perennial Root; the Flower is naked, and conſiſts of five or ſix Petals, which expand in form of a Roſe, garniſh'd with five Stamina; in the Middle of the Flower riſes the Pointal, which afterwards becomes a Bladder, containing many ſpherical Seeds.

We have but one *Species* of this Plant in the *Engliſh* Gardens, which is;

Leontopetalon *foliis coſtæ ramoſæ innaſcentibus*. *Flor.* Lion-leaf, with Leaves growing on a branched Rib.

This Plant is found in great Plenty in the Iſlands of the *Archipelago*, and alſo in ſome Parts of *Italy*, but at preſent is very rare in *England*; it may be propagated by ſowing the Seeds, or parting of the Roots; but the former is the beſt Method, if the Seeds could be obtain'd from Abroad; for they ſeldom produce good Seeds in *England*, nor do they increaſe very faſt by their Roots.

The Seed of this Plant ſhould be ſown ſoon after it is ripe, in Pots or Tubs fill'd with freſh light Earth, that the Plants may be removed into Shelter in the Winter; for if they are expoſed at that Seaſon, (which is the Time they do ariſe) the Cold will deſtroy them; but in the Summer they ſhould be ſet abroad, where they may have the Morning Sun until Ten of the Clock; and when the Plants are ſtrong enough to be tranſplanted, they ſhould be each of them put into a ſeparate Pot, and in Winter placed into a Hot-bed Frame, where they may be ſhelter'd in ſevere Froſts; but in mild Weather they ſhould be expoſed to the open Air.

When the Plants are two Years old, they may be taken out of the Pots, and planted into a warmer Border under a South Wall, where they will endure the Cold of our ordinary Winters very well, being ſeldom hurt by ſevere Froſts, or too much Wet; for which Reaſon they ſhould always be planted in a dry Soil.

The beſt Seaſon for tranſplanting theſe Roots is in *May*, when their Leaves are decay'd; for if you defer it till *July* or *Auguſt*, they will be ſtriking out new Roots, when they will not be ſo ſafely removed. They produce their Flowers in Winter, for which they are chiefly valued.

LEONTOPODIUM. *Vide* Plantago.

LEONURUS, [Λεώνουρος, of λέων, a *Lion*, and οὐρὰ, a *Tail*, becauſe the Creſt of this Flower ſeems to reſemble the Tail of a Lion] Lion's-tail.

The *Characters* are;

It is one of the verticillate Plants with a Lip Flower, which conſiſts of one Leaf, whoſe Galea or Creſt is imbricated, and much longer than the under Lip, which is divided into three Segments; out of the Flower-cup riſes the Pointal, fix'd like a Nail to the hinder Part of the Flower, ſurrounded by four Em-

bryo's, which afterwards turn to ſo many Seeds, which are oblong, and incloſed in a long fiſtulous Huſk, which before was the Flower-cup.

The *Species* are;

1. LEONURUS *perennis Africanus, ſideritidis folio, flore Phœnicio majore. Breyn. Prod.* Perennial *African* Lion's-tail, with an Iron-wort Leaf, and a large ſcarlet Flower.

2. LEONURUS *perennis Africanus, ſideritidis folio variegato, flore Phœnicio majore.* Perennial *African* Lion's-tail, with a variegated Iron-wort Leaf, and a large ſcarlet Flower.

3. LEONURUS *minor, Capitis Bonæ Spei, vulgo. Boerh. Ind.* Leſſer Lion's-tail from the *Cape of Good Hope*, with a Catmint Leaf.

Theſe Plants are very great Ornaments in a Green-houſe, producing large Tufts of beautiful ſcarlet Flowers in the Months of *October* and *November*, when few other Plants are in Perfection; for which Reaſon a good Green-houſe ſhould never be wanting of theſe Plants, eſpecially ſince they require no artificial Heat, but only to be preſerved from hard Froſts, ſo that they may be placed amongſt *Oranges*, *Myrtles*, *Oleanders*, &c. in ſuch a Manner, as not to be too much over-ſhaded with other Plants; but that they may enjoy as much free Air as poſſible in mild Weather.

They are eaſily propagated by planting Cuttings of any of the Sorts, in Pots fill'd with light Earth, any Time in *July* or *Auguſt*, obſerving to ſhade and water them until they have taken Root; after which they muſt be each of them planted into a ſeparate Pot fill'd with light rich Earth, and often refreſh'd with Water, (for it is an Aquatick Plant in its native Country) and in *October* they muſt be removed into the Green-houſe; but in *May*, they ſhould be expoſed again to the open Air, placing them where they may have the Morning Sun till Eleven of the Clock, obſerving never to let them want Water, which will encourage them to produce ſtrong Tufts of Flowers in Autumn.

Theſe Plants will grow to be eight or nine Feet high, and abide many Years; but are very ſubject to grow irregular; therefore their Branches ſhould be pruned early in the Spring, in order to reduce them to a tolerable Figure; but they will not bear to be often pruned or ſheer'd, nor can they ever be form'd into Balls or Pyramids; for if they are often ſhorten'd, it will prevent their flowering.

The ſtriped Sort is by many People valued for the Variety of its Leaves; but as that is occaſion'd by a Weakneſs in the Plant, ſo the Flowers of that Sort are never ſo large and fair, as are thoſe of the plain Sort, nor produced in ſo great a Quantity.

The third Sort is alſo preſerv'd for Variety more than its Beauty; the Flowers of this being much ſmaller, and not ſo well colour'd, as are thoſe of the common Sorts.

LEPIDIUM, Dittander or Pepperwort.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs, from whoſe Cup ariſes the Piſtillum, which afterward becomes a ſpear-ſhaped Fruit, which is divided in the Middle by a Partition into two Cells, which contain many oblong Seeds.

The *Species* are;

1. LEPIDIUM *latifolium. C. B. P.* Common broad-leav'd Dittander, or Poor-man's Pepper.

2. LEPIDIUM *humile incanum arvenſe. Inſt. R. H.* Low hoary Dittander, or Pepperwort.

3. LEPIDIUM *gramineo folio, ſive Iberis. Inſt. R. H.* Graſs-leav'd Dittander, or Sciatica Creſs.

4. LEPIDIUM *humile, minus incanum, Alepicum. Inſt. R. H.* Low greener Dittander of *Aleppo*.

5. LEPIDIUM *capillaceo folio, fruticoſum Hiſpanicum. Inſt. R. H.* Shrubby *Spaniſh* Dittander, with very narrow Leaves.

6. LEPIDIUM *Orientale, naſturtii criſpi folio. Tourn. Cor.* Eaſtern Dittander, with a curled creſs Leaf.

7. LEPIDIUM *Orientale, naſturtii folio, caule veſicario. Tourn. Cor.* Eaſtern Dittander, with a creſs Leaf, and a ſwelling Stalk.

8. LEPIDIUM *Orientale, caryophylli folio. Tourn. Cor.* Eaſtern Dittander, with a clove-gilly-flower Leaf.

The firſt and third Sorts are directed by the College of Phyſicians to be uſed in Medicine. The firſt grows wild in ſome Parts of *England*, but is generally cultivated in Gardens for Uſe. The Herb and Root of this Sort were formerly uſed in Sauce, to give a warm biting Taſte thereto; and ſome poor People have mixed a few of the Leaves in their Sallets, for the ſame Purpoſe. This Sort is eaſily propagated, by planting any ſmall Pieces of the Root, either in Spring or Autumn, after the Manner directed for *Horſe Radiſh*; but it ſhould be placed in ſome odd Corner of the Garden, and not near other Plants, becauſe the Roots will ſpread and ſhoot up at a great Diſtance, ſo as to over-run the Ground where it is planted.

The third Sort may be propagated by Seeds, which ſhould be ſown in the Spring; and when the Plants are come up, they ſhould be thinned, ſo as to leave them eight or ten Inches aſunder, and keep them clear from Weeds; which is all the Culture they require. The ſecond Year the Plants will produce Seeds, and the old Roots will remain ſeveral Years, provided they are not in too rich Ground. The Leaves and Seeds of this Plant are uſed in Medicine.

The ſecond and fourth Sorts are trailing Plants, which propagate very faſt by their creeping Roots: Theſe are preſerved in botanick Gardens for Variety, but there is little Beauty in them.

The fifth Sort was diſcovered by Doctor *Tournefort* in *Spain*. This grows ſhrubby, and will abide the Cold of our ordinary Winters in the open Air, provided it is planted on a poor dry Soil. It may be propagated either by Seeds or Cuttings.

The other three Sorts were diſcovered by Doctor *Tournefort* in the *Levant*, from whence he ſent their Seeds to the *Royal Garden* at *Paris*. Theſe are alſo preſerved in botanick Gardens for the ſake of Variety, and may be eaſily propagated by Seeds.

LEPIDOCARPODENDRON.

We have no *Engliſh* Name for this *Genus*.

The *Characters* are;

It hath a large ſcaly Flower-cup, in which are included many Florets, ſome of which are apetalous, and appear like Hairs, and other are hermaphrodite; from the Middle of the Flowers ariſes the Ovary, which is incloſed in a Sheath; the Seeds have long Plumes like Feathers adhering to them.

The *Species* are;

1. LEPIDOCARPODENDRON *folio ſaligno lato, caule purpuraſcente. Boerh.* Lepidocarpodendron with a broad Willow Leaf, and a purpliſh Stalk.

2. LEPIDOCARPODENDRON *foliis anguſtis longis ſalignis, nervo rubro, florum plumis violaceo-purpureis. Boerh.* Lepidocarpodendron with long narrow Willow Leaves, having a red Vein, and the Plumes of the Flowers of a violet-purple Colour.

3. LEPIDOCARPODENDRON *foliis anguſtiſſimis gramineis, fructu cancellato, ſemine coronato. Boerh.* Lepidocarpodendron with very narrow Graſs Leaves, a hooded Fruit, and a crowned Seed.

There are ſeveral other Sorts of theſe Trees, which naturally grow in the Country near the *Cape of Good Hope*, from whence thoſe here mentioned were brought into the *European* Gardens; where they are preſerved by the Curious to add to the Variety in the Green-houſe.

Theſe Plants may be propagated in the ſame Manner as hath been directed for *Conocarpodendron*, and the Plants may alſo be treated as thoſe; ſo it will be needleſs to repeat it in this Place.

LETTUCE. *Vide* Lactuca.

LEUCANTHEMUM, [Λευκάνθεμον, of λεύκος, *White*, and ἄνθεμος, a *Flower*] Ox-eye Daizy.

The *Characters* are;

It agrees in every reſpect with the Chryſanthemum, *except in the Colour of its Semi-florets, which in theſe are conſtantly White.*

The *Species* are;

1. LEUCANTHEMUM *vulgare. Tourn.* Common Ox-eye Daizy.

2. LEUCANTHEMUM *Alpinum majus, rigido folio. Tourn.* Greater Ox-eye Daizy of the *Alps*, with ſtiff Leaves.

3. LEUCANTHEMUM *radice repente, foliis latioribus ſerratis. Tourn.* Creeping-rooted Ox-eye Daizy, with broad ſerrated Leaves.

4. LEUCANTHEMUM *folio abſinthii, Alpinum. Ciaſſi.* Alpine Ox-eye Daizy, with a Wormwood Leaf.

5. LEUCANTHEMUM *tanaceti folio, flore majore. Boerh. Ind.* Ox-eye Daizy, with a Tanſy Leaf, and a large Flower.

6. LEUCANTHEMUM *Canarienſe, foliis chryſanthemi, ſapore pyrethri. Tourn.* Canary Ox-eye Daizy, with a Chryſanthemum Leaf, and a Taſte like Pellitory of *Spain*, vulgarly call'd *Pellitory of Spain.*

7. LEUCANTHEMUM *montanum, foliis chryſanthemi. Inſt. R. H.* Mountain Ox-eye Daizy, with Corn-marygold Leaves.

8. LEUCANTHEMUM *gramineo folio. Inſt. R. H.* Graſs-leav'd Ox-eye Daizy.

9. LEUCANTHEMUM *latiſſimo folio, flore maximo. Inſt. R. H.* Broadeſt-leav'd Ox-eye Daizy, with a large Flower.

10. LEUCANTHEMUM *Luſitanicum, argenteo laciniato folio. Inſt. R. H. Portugal* Ox-eye Daizy, with a ſilver jagged Leaf.

11. LEUCANTHEMUM *Americanum fruteſcens, foliis latis conjugatis & aſperis, flore albo, capitulis ſquamoſis. Houſt.* Shrubby *American* Ox-eye Daizy, with broad rough Leaves growing oppoſite, a white Flower, and a ſcaly Cup.

The firſt of theſe Plants is very common in the Meadows, in moſt Parts of *England*, from whence the Flowers are gather'd and brought into the Markets in *London* for Medicinal Uſes; but it is ſeldom cultivated in Gardens.

The ſecond and fifth Sorts are many Times planted in Gardens, for their Beauty; theſe produce large Tufts of white radiated Flowers upon the Summits of their Stalks, which continue a long Time in Beauty; they commonly grow two Feet high or more; for which Reaſon they ſhould always be placed in the Middle of large Borders, and require to be planted at a good Diſtance from other Plants, otherwiſe they will over-bear them: ſo that they are not very proper for ſmall Gardens, taking up too much Room.

Theſe are very hardy Plants, and may be propagated either by ſowing their Seeds, or parting their Roots: The beſt Time for ſowing of their Seeds, is in *March*, upon a Border of light freſh Earth; and when the Plants are come up pretty ſtrong, they muſt be tranſplanted into freſh Borders of the like Earth, placing them at eight Inches Diſtance each Way: In theſe Borders they may remain till *Michaelmas*, when they ſhould be removed into the Borders where they are to continue, and the Summer following they will produce Flowers and Seeds.

But if you would propagate them by parting their Roots, the beſt Seaſon for this Work is in *September* or *October*; for if it be done in the Spring, they ſeldom flower ſo ſtrong the ſucceeding Summer.

The third Sort multiplies too faſt by its creeping Roots, which will ſpread and come up at a great Diſtance from the old Plant, ſo that it is hardly to be kept within tolerable Bounds; but it is very apt to run over whatever Plants ſtand near; for which Reaſon it ſhould never be placed amongſt choice Flowers, but allow'd a Place in ſome abject Part of the Garden, in a Corner allotted to it, where it will grow to the Height of four Feet, and produce large radiated white Flowers in *Auguſt* and *September*.

The fourth Sort is ſeldom admitted into curious Flower-Gardens, it being a rambling Plant, and the Branches trailing upon the Ground, renders it unſightly, nor are the Flowers very beautiful; ſo that it is ſeldom preſerv'd but in botanick Gardens.

Theſe are all very hardy Plants, and will grow in almoſt any Soil or Situation, and there being very little Trouble in their Culture, they deſerve Room in all large Gardens.

The ſixth Sort is tenderer than any of the former, and muſt be preſerv'd in Pots and ſhelter'd in the Winter. This is propagated by planting Cuttings, in any of the Summer Months, into a Border of light Earth, obſerving to water and ſhade them from the great Heat of the Sun until they have taken Root; after which they muſt be planted into Pots fill'd with light freſh Earth, and expoſed to the open Air until the Middle or latter End of *October*, when they muſt be houſed; but ſhould be placed into the cooleſt Part of the Houſe, where they may have much free Air in mild Weather, and muſt be frequently refreſh'd with Water; but in Summer-time they may be expoſed to the open Air, in a ſhady Situation, where they will thrive much better than if expoſed to the Sun, which would dry the Earth too faſt, ſo that they would conſtantly require to be water'd.

This Plant is not apt to continue above two or three Years without renewing; therefore Cuttings ſhould be planted every other Year, to maintain the Kind, where People are curious to preſerve their Varieties. There is no great Beauty in this Plant; but it is preſerv'd in ſome Gardens, for the true *Pellitory of Spain*, which, in reality, is a different Plant; tho' this has a very ſharp acrid Taſte, much like that of the *Pellitory*.

The ſeventh, eighth, ninth, and tenth Sorts are hardy Plants, which will live in the open Air in *England*: They may be propagated by ſowing of their Seeds on a Bed of light freſh Earth, in the Beginning of *March*; and when the Plants begin to appear, they ſhould be carefully clear'd from Weeds, and in very dry Weather they ſhould be refreſhed with Water, which will greatly promote their Growth. When they are about two Inches high, they ſhould be tranſplanted into Beds, at about eight Inches Diſtance, obſerving to water them until they have taken new Root, after which Time they will require no other Care, but to keep them clear from Weeds, till the Autumn following, when they ſhould be tranſplanted into the large Borders of the Pleaſure-Garden, where they are deſigned to remain: In which Places they will afford an agreeable Variety, when intermixed with other hardy flowering Plants, and will abide a long Time.

The eleventh Sort was diſcovered by the late Doctor *William Houſtoun* at *Campechy*, from whence he ſent the Seeds into *Europe*, whereby many Gardens have been ſtored with this Plant. This Sort being a Native of a warm Country, will not live in this Climate, unleſs it is placed in a Stove in the Winter: But in the Middle of Summer, it will abide the open Air in a warm Situation, and will thrive better at that Seaſon abroad, than if it were kept in the Stove; becauſe the Leaves of this Plant are very ſubject to contract Filth, and Inſects lodge upon them, whereby the Plants are rendered unſightly, and ſeldom thrive. This Sort may be propagated by Cuttings during the Summer Months, which ſhould be planted in Pots filled with freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them until they have taken Root, and give them plenty of Water: And when the Cuttings are rooted, they ſhould be placed in the open Air in a warm Situation, where they may remain until the latter End of *September*, when they ſhould be removed into the Stove; obſerving to let them have a large Share of freſh Air in the Day-time, while the Weather continues moderate; but as the Cold increaſes, ſo they ſhould be ſecured therefrom. Theſe Plants require but a moderate Warmth in Winter, ſo ſhould be placed with the more hardy Stove-Plants, and will require to be often refreſhed with Water. With this Management, the Plants will grow eight or ten Feet high, and add to the Variety in the Stove.

LEUCOJUM, [Λευκόϊον, of λευκὸν, *White*, and ἴον, a *Violet*, i. e. *White Violet*] Stock-Gilliflower.

The *Characters* are;

The Flower is compoſed for the moſt part of four Leaves, which are placed in Form of a Croſs; out of the Flower-cup riſes the Pointal, which becomes a long flat Pod, divided into two Cells by an intermediate Partition, to which the Valves adhere on both Sides, and are furniſh'd with flat ſmooth Seeds, which are orbicular, and border'd round their Edges: to which may be added, the Flowers are ſpecious and ſweet-ſmelling.

The *Species* are;

1. LEUCOJUM *incanum majus. C. B. P.* Great hoary Stock-Gilliflower, with ſingle white Flowers.

2. LEUCOJUM *incanum majus, flore cinericeo. C. B. P.* The great hoary Stock-Gilliflower, with an Aſh-colour'd Flower.

3. LEUCOJUM *purpureum, vel rubrum. C. B. P.* Purple or Red Stock-Gilliflower.

4. LEUCOJUM *incanum majus, coccineum. Mor. Hiſt.* The greater hoary crimſon Stock-Gilliflower, *vulgarly call'd* the Brumpton Stock.

5. LEUCOJUM *violaceum. Tabern.* Violet-colour'd Stock-Gilliflower.

6. LEUCOJUM *incanum majus multiplex, flore purpureo. C. B. P.* Greater hoary Stock-Gilliflower, with a double purple Flower.

7. LEUCOJUM *incanum majus multiplex, flore rubro. C. B. P.* Greater hoary Stock-Gilliflower, with a double red Flower.

8. LEUCOJUM *incanum majus multiplex, flore albo. Tourn.* Greater hoary Stock-Gilliflower, with a double white Flower.

9. LEUCOJUM *incanum majus variegatum, pleno flore. C. B. P.* The greater hoary Stock-Gilliflower, with a double variegated Flower.

10. LEUCOJUM *majus incanum variegatum album, flore ſimplici, maculis in albo rubris. C. B. P.* The greater hoary Stock-Gilliflower, with a ſingle white Flower ſpotted and ſtrip'd with Red.

11. Leucojum *pleno flore, album, ſanguineis maculis ſignatum. Hort. Eyſt.* White Stock-Gilliflower, with a double Flower, mark'd with bloody Spots.

12. Leucojum *pleno flore, album, purpureis maculis ſignatum. Hort. Eyſt.* White Stock-Gilliflower, with a double Flower mark'd with purple Spots.

13. Leucojum *incanum majus variegatum, pleno flore, foliis in ambitu argenteis. H. L.* The greater hoary, variegated Stock-Gilliflower, with a double Flower, and Leaves edg'd with Silver.

14. Leucojum *minus & annuum. Dod.* Leſſer annual Stock-Gilliflower.

15. Leucojum *album odoratiſſimum, folio viridi. C. B. P.* The moſt ſweet-ſmelling Stock-Gilliflower, with a green Leaf, commonly call'd the *White Wall-flower*.

16. Leucojum *album odoratiſſimum, folio viridi, pleno flore.* The double white Wall-flower, *vulgo*.

17. Leucojum *luteum vulgare. C. B. P.* The common yellow Wall-flower.

18. Leucojum *luteum, flore pleno, minus. C. B. P.* The common double Wall-flower.

19. Leucojum *anguſtifolium Alpinum, flore ſulphureo. H. R. Par.* Narrow-leav'd *Alpine* Wall-flower, with a Brimſtone colour'd Flower.

20. Leucojum *anguſtifolium Alpinum, flore pleno ſulphureo.* Narrow-leav'd *Alpine* Wall-flower, with a double Brimſtone-colour'd Flower, commonly call'd the *Straw-colour'd Wall-flower*.

21. Leucojum *luteum, magno flore. C. B. P.* Wall-flower, with a large Flower.

22. Leucojum *luteum, flore pleno, majus. C. B. P.* The greater Wall-flower, with a double Flower.

23. Leucojum *majus, flore intus luteo, extus ferrugineo.* Greater Wall-flower, with larger Flowers, yellow within, and on the out-ſide of an Iron-colour, commonly call'd the *Ravenal Wall-flower*.

24. Leucojum *majus, flore majore pleno, intus luteo, extus ferrugineo.* The double Ravenal, *vulgo*.

25. Leucojum *majus, flore pleno ferrugineo. Tourn.* The old double bloody Wall-flower.

26. Leucojum *luteum, pleno flore, foliis ex luteo variegatis.* The yellow variegated Wall-flower, with a double Flower.

27. Leucojum *luteum, pleno flore, foliis ex albo eleganter variegatis.* The Silver-ſtrip'd Wall-flower, with a double Flower.

There are ſeveral other Varieties of theſe Flowers, which are preſerv'd in ſome curious Botanick Gardens; but thoſe here mentioned, are the moſt beautiful, and beſt worth propagating in all curious Flower-Gardens.

All the Sorts of *Stock-Gilliflowers* are propagated by Seeds: The beſt Time for ſowing 'em is in the Beginning of *April*, upon a Border of freſh light Earth, where they may be expos'd to the Morning Sun; for if they are too much expos'd to the Sun in the Heat of the Day, they are very ſubject to be eaten by a Sort of Fly, as they often are while young, upon a hot dry Soil: To remedy which, you ſhould always ſow a few *Radiſhes* amongſt them, which will ſecure 'em from this Miſchief: for the Flies will always prey upon the *Radiſhes*, whereby your *Gilliflower* Plants will be preſerved; but then you muſt not ſuffer the *Radiſhes* to be too thick amongſt them, for that would draw 'em up very weak, and cauſe 'em to be long-ſhank'd. When your Plants have gotten ſix Leaves, they muſt be tranſplanted into other Borders of the like freſh Earth, and expos'd to the Morning Sun at about four Inches Diſtance, obſerving to water and ſhade 'em until they have taken Root; after which, they will require no farther Care, than only to keep them clear from Weeds until the Latter-end of *Auguſt*, or the Beginning of *September*, when you muſt tranſplant them into the Borders of the *Pleaſure-Garden*; which ſhould be done, if poſſible, in moiſt Weather, that they may the ſooner ſtrike Root, whereby they will be ſecurely faſten'd in the Ground before the Froſt comes on, which would prevent their taking Root, and thereby either quite deſtroy them, or at leaſt cauſe 'em to flower very weak the ſucceeding Spring.

There are many People who make a great Stir about ſowing theſe Seeds, and tranſplanting the Plants always at the ſame Time when the Moon is at the Full, in order to obtain a greater Number of double Flowers: but from ſeveral Years Obſervation, I could never obſerve any thing in this Management, nor from the frequently removing the Plants, as is by ſome directed, which only weakens them, and cauſes 'em to produce ſmaller Bunches of Flowers; but I could not find any more of them come double by this Management, than if they had never been remov'd: But the beſt Method that I have obſerv'd, to have theſe Flowers in the greateſt Perfection, is to change the Seeds every Year, if you can procure a good Correſpondent at ſome Place at a great Diſtance from you, who will faithfully furniſh you with good Seeds: And in ſaving theſe Seeds, if you obſerve a greater Number of Petals than uſual in the ſingle Flowers, it is a good Sign that the Seeds of ſuch Plants will produce double Flowers.

As theſe Plants are commonly biennial, and ſeldom continue longer than the ſecond Year, ſo there will be a Neceſſity of ſowing Seeds every Year; for when they have flower'd and ſeeded, they commonly decay ſoon after, as alſo do the Double Flowers ſoon after they are out of Flower; or if ſome of them ſhould continue another Year, they are ſeldom ſo ſtrong, or produce ſo fair Flowers as the young ſeedling Plants: ſo that, upon the whole, they are ſcarcely worth ſtanding. And tho' ſome People recommend the propagating the Double Sorts from Slips and Cuttings, as the ſureſt Way to have Double Flowers, which indeed is very true; yet the Plants thus rais'd are always weaker than thoſe rais'd from Seeds, and never produce their Flowers near ſo large or fair: Wherefore, (as I ſaid before) it is better to have a Succeſſion of ſeedling Plants every Year, amongſt which you will always have a Quantity of Double Flowers, provided your Seed be good.

The *Brompton Stock-Gilliflower* is by many People moſt valu'd, for the Largeneſs of its Flowers, and the Brightneſs of their Colour: but this Sort ſeldom produces more than one Spike of Flowers upon a Plant; whereas the *Italian* and *Purple* Sorts produce ſeveral very fair Bunches upon each Plant, eſpecially if they have Strength: And there is a Sort commonly call'd the *Stock-major*, (which, probably, is the ſeventh Sort here mention'd) which branches out on every Side, and produces many fair Spikes of Flowers from one Root; theſe are of a beautiful red Colour: As doth another Sort, commonly (tho' falſely) call'd the *Annual Stock*, which will produce its Flowers the firſt Year from Seed; but then the Plants commonly continue the next Seaſon, and flower again very ſtrong, and theſe often produce ſome Variety in the Colour of their Flowers, ſome being of a beautiful Scarlet, and others of a pale red Colour, and ſome of them are finely variegated; and theſe all produc'd from Seeds taken from the ſame Plant: But this Sort is very apt to degenerate, if the Seeds are not frequently changed.

The ſmall Annual *Stock-Gilliflower* will produce Flowers in about ten Weeks after ſowing, (which has occaſion'd its being call'd the *Ten Weeks Stock)*; and if the Seaſon be tolerably cool and moiſt, theſe Flowers will be very large: And many times there are large Double Flowers produc'd among them, which renders them well worth propagating, eſpecially if you ſow them in *May*, which will cauſe them to flower in *Auguſt* and *September*, when Flowers are beginning to be ſcarce in the Gardens. Theſe Plants produce ripe Seeds the ſame Year, and rarely ſurvive thro' a Winter.

Theſe Plants ſhould all be planted in a freſh light Soil, which muſt not be dung'd; for they don't do ſo well upon a rich Soil, in which they are apt to grow very rank, and then their Roots canker and decay; ſo that they ſeldom abide the Winter in ſuch Soils; but in a freſh Soil they will ſtand our ordinary Winters extremely well, and will produce large fair Flowers.

The Common Single *Wall-flower* is very ſeldom cultivated in Gardens, but is often found growing upon old Walls and Buildings in divers Parts of *England*: This is the Sort which is directed in the College *Diſpenſatory* for medicinal Uſes. But the Double of this Kind is very common in moſt of the *Engliſh* Gardens, which is propagated by planting Slips or Cuttings in any of the Spring Months, obſerving to water and ſhade them until they have taken Root; after which they may be remov'd to the Places where they are to remain.

The Straw-colour'd *Wall-flower* with Double Flowers was formerly more common in the *Engliſh* Gardens than at preſent: This is a much finer Sort for Shew than the Common, the Plants generally growing more upright; and the Spikes of Flowers are much larger, and grow much cloſer together than thoſe: But the Flowers have very little Scent; which, I ſuppoſe, has occaſion'd its being leſs cultivated than it was formerly; tho' indeed, for Shew, it is inferior to none of the Sorts of *Wall-flowers*: This is alſo propagated by Slips, as the Common Sort.

The White *Wall-flower* is propagated by ſowing the Seeds in *April*, in the manner before directed for the *Stock-Gilliflowers*; and if the Seeds are good, there will be many Double Flowers produc'd amongſt them, which may be continu'd, by planting the Slips in the ſame manner as has been directed for the Common *Wall-flower*. But the Double of this Kind being ſomewhat tenderer than the other Sorts of *Wall-flowers*, ſhould be planted into Pots fill'd with light freſh Earth, and in the Winter Seaſon ſhould be plac'd under a Hot-bed Frame, where they may be ſhelter'd from ſevere Froſts; but in mild Weather they ſhould have as much free open Air as poſſible; in which Management they will endure two or three Years, and produce fair Flowers.

The large flowering *Wall-flower* is alſo propagated by Seeds, in the ſame manner as the *Stock-Gilliflowers*; for tho' it will grow from Slips, yet theſe ſeldom make ſo good Plants as thoſe produc'd from Seeds, nor will they flower ſo ſtrong. This Sort rarely produces many Double Flowers, but yet is well worth propagating, for the Largeneſs and Sweetneſs of its Flowers; and if they are planted in a very poor dry Soil, will continue two or three Years, and endure the Cold extremely well.

The *Ravenal Wall-flower* is at preſent in the greateſt Eſteem with the curious Floriſts, the Flowers of this Kind being full as large as the laſt-mention'd Sort, and are of a fine reddiſh or Iron Colour on the Outſide, as alſo of an extraordinary Sweetneſs; and this is more apt to produce Double Flowers than the former: It is propagated by Seeds, which ſhould be ſown in *March*, and manag'd as was directed for the *Stock-Gilliflower*, obſerving never to plant them in a rich Soil, which will cauſe them to grow very faſt during the Summer Seaſon; but they ſeldom endure the Winter in ſuch Soils. The Double-flower'd Plants of this Kind may alſo be propagated by Slips, in the ſame manner as the before-mention'd Sorts; but theſe ſhould be ſhelter'd in Winter, as was directed for the White *Wall-flower*, otherwiſe they are ſubject to be kill'd by very ſharp Froſts. The Seeds of this Kind ſhould be often chang'd, or elſe they will greatly degenerate.

The old Double Bloody *Wall-flower* was formerly more common in *England* than at preſent, it being at this Time rarely to be ſeen: This is a Variety of the Common Double *Wall-flower*, from which it only differs in having the Outſide of the Petals of a Bloody Colour: It may be propagated by Slips, as the Common Sort; but requires to be ſhelter'd from extreme Cold in the Winter, which often deſtroys theſe Plants if they are too much expos'd to it.

The Yellow-ſtrip'd *Wall-flower* is alſo a Variety of the Common Double Sort, having its Leaves beautifully variegated in the Spring and Winter Seaſon; but in the Summer, when the Plants are very free of Growth, they degenerate to be almoſt quite plain, ſo that at that Seaſon there is very little Beauty in them: This is alſo propagated by Slips, as the Common Sort; but ſhould be planted in a warm Situation, otherwiſe it will often ſuffer by great Colds in Winter.

The Silver-ſtrip'd *Wall-flower* is much more beautiful than the laſt, and generally retains its beautiful Variegation through the whole Year: This is propagated by Slips, as the former; but ſhould be ſhelter'd in Winter, being much tenderer than the laſt; for which Reaſon, the Plants ſhould be ſet into Pots, and treated as the Double White *Wall-flower*: But you ſhould obſerve, never to plant them in a rich Soil, which will cauſe them to become plain, (as I have often obſerv'd): nor ſhould they have too much Moiſture, which very often deſtroys 'em.

All the Sorts of *Wall-flowers* will abide the Cold much better if planted in a very gravelly and ſtony Soil, than when they are in a rich Earth, as may be obſerv'd by thoſe which grow upon the Tops of Walls, and other Buildings, where ſometimes they are very much expos'd to the cold Winds, and yet often endure the ſharpeſt Winters; when thoſe which were planted in a good Soil have been deſtroy'd, notwithſtanding they have a warm Situation.

LEVEL, a Mathematical Inſtrument, ſerving to draw a Line parallel to Horizon, not only for various Uſes in *Maſonry*, &c. but alſo to meaſure the Difference of Aſcent and Deſcent between ſeveral Places, for the Conveying of Water, Draining of Fens, *&c.*

A *Water Level* ſhews the horizontal Line, by means of a Surface of Water, or other Liquid, founded on this Principle, that Water always naturally places itſelf *level*.

The moſt ſimple Inſtrument for this Uſe, is made of a long wooden Trough or Canal whoſe Sides are parallel to its Baſe; ſo that being equally fill'd with Water, the Surface thereof ſhews the Line of *Level*.

This *Level* is alſo made with two Cups fill'd to the two Ends of a Pipe three or four Feet long, about an Inch in diameter; by means whereof, the Water communicates from the one to the other Cup; and this Pipe being moveable on its Stand, by means of a Ball and Socket, when the two Cups become equally full of Water, the two Surfaces mark the Line of *Level*.

Inſtead of Cups, this Inſtrument may be made with two ſhort Cylinders of Glaſs three or four Inches long, faſten'd to each End of the Pipe with Wax or Maſtick; then the Pipe being fill'd either with common or colour'd Water, will ſhew itſelf through the Cylinder, by means of which the *Line of Level* is determin'd; the Height of the Water, with reſpect to the Center of the Earth, being always the ſame in both Cylinders. This *Level* is very commodious in Levelling ſmall Diſtances.

If you would level any Piece of Ground that you can ſee from Side to Side, or from the Middle to any Side, ſet up your Inſtrument in the Middle of it, whether it be a *Water Level* or a *Ground Level* with Sights: Place it ſo high, that you may ſee over the higheſt Part of the Ground half a Foot, or a Foot; then ſet up a Stake in the Middle, ſo that the Top may be exactly level with the Sights, and another Stake on the higheſt Side, the Top of which muſt be level with the middle Stake: Then either turn the *Level* or Look-back Sight, and ſet up another Stake on the Lower Ground level with the two firſt; ſo then you will have three Stakes ſtanding in a *Level*.

Then keeping your *Level* true to the middle Stake, turn it till it makes right Angles with the three Stakes, and ſet up two Stakes on each Side one, *Level* with thoſe three: ſo that then you will have five Stakes in two Lines ſet true *Level*.

If the Ground be large, you may ſet up two Rows more by the *Level*; but five Stakes are enough in a ſmall Ground.

When this is done, you may lay your *Level* aſide, and look over the Head of one to the Head of another, and cauſe the Perſon who aſſiſts you to put down Stakes between two and two, till you have ſet as many Stakes *Level* in the Ground as you think convenient; or you may uſe a Rule, which being plac'd level with the Head of the Stake, you may look over that to the Head of the other, and put Stakes down between you and the other Stake to what Number you pleaſe.

The Ground being thus ſtaked out, with all the Stakes Heads level, and half a Foot higher than the higheſt Ground, in ſome Grounds the middle Stakes and the Stakes in the Croſs-Line will be the Level-Line the Ground muſt be brought to; that is, abating the Hill, and filling up the Low Side to the *Level* of the Mid-Line. But if the Ground be very uneven, then you muſt meaſure over all the Stakes, and take them middle high for their Mean-*Level*, and, by the *Rule of Three*, proportion your Ground to that.

As for Inſtance: If a Valley be ten Poles in Length, and two Feet in Depth from the ſtrait Line, and there be a Hill five Poles long; How many Feet deep muſt a Perſon ſink thoſe five Poles to fill up the Valley? This Queſtion may be reſolv'd by the Inverſe or Back *Rule of Three*, and will ſtand thus; As 5 is to 2, ſo is 10 to 4.

5 —— 2 —— 10
2
———
5)20(4

So that a Perſon muſt go four Feet deep in ſuch a Hill to make good ſuch a Valley.

If you are to abutt the Top of a Hill four Feet deep, and two Poles from the Top of that Hill, thoſe four Feet are to come out.

To perform this, ſet up a Stake on the Top of a Hill two or three Feet above Ground, and another of the ſame Height where the Depth comes out; ſet down a Stake three Rods from that, till the Head comes to be in a Line with theſe two, and at that Stake you muſt be one Foot deep.

At ſix Poles, ſtake down another, as before, and there you muſt be two Feet deep: Then ſtake down another at nine Poles, and there you muſt be three Feet deep; and you may ſet more Stakes at equal Diſtances, which will direct you ſo as that you cannot go amiſs.

LEVITY, is the Privation or Want of Weight in any Body, when compar'd with another that is heavier, in which Senſe it is oppos'd to *Gravity*.

The School-men maintain, that there is ſuch a Thing as Poſitive and abſolute *Levity*, and impute this to Riſe and Emergency of Bodies lighter in Specie than the Fluids wherein they riſe.

But beſides that the common Senſe of Mankind diſcovers that *Levity* is only a relative Term; we find that all Bodies tend towards the Earth, ſome ſlower, and ſome faſter, in all Fluids or Mediums, whether Water, Air, *&c.*

Thus Cork is ſaid to be lighter than Gold, becauſe under equal Dimenſions of Bulk the Gold will ſink in, and the Cork ſwim upon the Water.

Archimedes has demonſtrated, that a ſolid Body will float any where in a Fluid of the ſame ſpecifick Gravity, and that a lighter Body will keep above a heavier.

The Reaſon of this is, becauſe Bodies falling towards the Earth, thoſe which have a like Number of equal Parts, have equal Gravity; ſince the Gravity of the Whole is the Sum of the Gravity of all its Parts.

Now two Bodies have an equal Number of equal Parts, if under the ſame Dimenſions there are no Intervals deſtitute of Matter: Whence it follows, that as no Portion of Matter is ſo ſmall, but that Body wherein it is contain'd may be wholly divided into Parts equally ſmall, there can be no Reaſon for the Deſcent of theſe, which will not equally hold for the Deſcent of that.

Hence it may be concluded, that thoſe Bodies which do not equally gravitate under the ſame Dimenſions, do not contain the ſame equal Portions of Matter; and therefore when we ſee that a Cube of Gold ſubſides in Water at the ſame time that an equal Bulk of Cork ſwims upon it, it is evident that the Gold muſt have a greater Number of equal Parts of Matter under the ſame Bulk than the Cork; or the Cork muſt have a greater Number of Vacuities than the Gold; and that there are alſo in the Water a greater Number of Vacuities than in the Gold.

Hence we have a clear Idea both of *Denſity* or *Gravity*, and of *Levity*; and know, that in a ſtrict Senſe, the latter cannot be accounted any thing poſitive, but a mere Negation or Abſence of Body, which determines that Body to be lighter than another which contains mere Matter.

LICHEN, Liverwort.

There being two Sorts of this Plant, which are uſed in Medicine, and one of thoſe being accounted a ſovereign Remedy for the Bite of Mad-dogs, ſo I thought it would not be improper to mention them here, tho' they are Plants which cannot be propagated by any Method, except by paring up the Turf of Graſs whereon they grow, and laying it down in ſome moiſt ſhady Place, where, if the Turf takes Root and thrives, theſe Plants will ſpread and do well. The two Sorts are;

1. LICHEN *petræus latifolius, ſive Hepatica fontana. C. B. P.* Common broad-leav'd Liverwort.
2. LICHEN *terreſtris cinereus. Raii Syn.* Aſh-coloured ground Liverwort.

The firſt Sort grows on the Sides of *Wells*, and in moiſt ſhady Places, not only on the Ground, but on Stones, Bricks or Wood. Of this there are ſeveral Varieties, which are diſtinguiſhed by the Curious in Botany; but as they are Plants of no Uſe, ſo I ſhall not enumerate them here.

The ſecond Sort (which is uſed to cure the Bite of Mad-dogs) grows on Commons and open Heaths, where the Graſs is ſhort, in moſt Parts of *England*, eſpecially on Declivities, and on the Sides of Pits. This ſpreads on the Surface of the Ground, and when in Perfection, is of an Aſh-colour; but as it grows old, it alters, and becomes of a Dark-colour. This is often carried into Gardens with the Turf which is laid for Walks and Slopes; and where the Soil is moiſt and cool, it will ſpread, and be difficult to deſtroy; ſo that it renders the Graſs unſightly: but this is the only Method yet known to have it grow in Gardens, where it is deſired.

This is eſteemed a ſovereign Remedy for the Bite of Mad-dogs, and hath been for many Years uſed with great Succeſs. It was communicated to the Royal Society, by Mr. *George Dampier*, whoſe Uncle had long uſed this Plant, to cure the Bite of Mad-dogs, on *Men* and *Animals*, with infallible Succeſs; the Method of taking it he has delivered as followeth: Take of the Herb, and dry it either in an Oven, by the Fire, or in the Sun; then powder it, and paſs it thro' a fine Sieve; mix this with an equal Quantity of fine powdered *Pepper*; the common Doſe of this Mixture is four Scruples, which may be taken in warm *Milk*, *Beer*, *Ale*, or *Broth*. He alſo adviſeth the Part bitten to be well waſhed, as alſo the Cloaths of the Perſon who is bit, leſt any of the *Snivel* or *Drivel* of the Mad-dog, ſhould remain. If the Perſon bitten be full-grown, he adviſed that he be blooded, before the Medicine is taken; and to uſe the Remedy as ſoon after the Bite as poſſible, as alſo to repeat the Doſe two or three ſeveral Mornings faſting.

LIGHT is us'd in various Senſes: 1. Sometimes it ſignifies that Senſation which is occaſion'd in the Mind by the View of luminous Bodies.

2. For thoſe Properties in thoſe Bodies, whereby they are fitted to excite thoſe Senſations in us.

3. A certain Action of the luminous Body on the Medium between that and the Eye, by the Means of which the one is ſuppos'd to act on the other; and this is call'd *ſecondary Light*, or *deriv'd Light*, in Diſtinction to that of luminous Bodies, which is call'd *primary* or *innate Light*.

As to the *Phænomenon* of *Light*, Philoſophers have explain'd it ſeveral ways: *Ariſtotle*, by ſuppoſing ſome Bodies to be tranſparent, as Air, Water, Ice, *&c.* The *Carteſians* have conſiderably refin'd upon this Motion of *Light*, and own that *Light*, as it exiſts in the luminous Body, is nothing elſe but a Power or Faculty of exciting in us a very clear and vivid Senſation: And Father *Malbranch* explains the Nature of *Light* by a ſuppos'd Analogy between it and Sound; the latter of which is allow'd to be produc'd by the ſhaking or Vibration of the inſenſible Parts of the ſonorous Body.

But the greateſt Diſcoveries into this wonderful *Phænomenon* have been made by Sir *Iſaac Newton*; That the Primary *Light* conſiſts wholly in a certain Motion of the Particles of the lucid Body, whereby they do not propel any fictitious Matter ſuppos'd to be lodg'd in the hidden Pores of tranſparent Bodies, but throw off from the luminous Body certain very ſmall Particles, which are emitted every Way with great Force.

And the *ſecondary* or *deriv'd Light*, not in a *Conatus*, but in a real Motion of theſe Particles receding every Way from the luminous Body in right Lines, and with an incredible Velocity.

For it hath been demonſtrated by Mr. *Romer*, from the Obſervation on the Satellites of *Jupiter*, that the Progreſs of *Light* from the Sun to our Earth is not above ten Minutes, and therefore, ſince the Earth is at leaſt 10,000 of its own Diameters diſtant from the Sun, *Light* muſt run 10,000 of thoſe Diameters in a Minute, which is above 100,000 Miles in a Second.

And if a Bullet moving with the ſame Celerity, with which it leaves the Muzzle of Cannon, requires twenty-five Years to paſs from the Earth to the Sun, as Mr. *Huygens* has computed, then the Velocity of *Light* will be to that of a Cannon-Ball, as twenty-five Years is to ten Minutes, which is above 10,000 to 1; ſo that the Particles of *Light* do move above a Million of times ſwifter than a Cannon Bullet; from which Rapidity of Motion very ſtrange Effects may be produc'd: But Sir *Iſaac Newton* has ſhewn, paſt Contradiction, that the *Light* of the Sun is near ſeven Minutes in its Paſſage to the Earth, which is the Space of 50,000,000, a Velocity 10,000,000 times greater than that wherewith a Ball flies out of the Mouth of a Cannon.

Sir *Iſaac Newton* alſo obſerves, That *Bodies* and *Light* act mutually on one another: *Bodies* on *Light* in emitting, reflexing, refracting, and inflecting it; and *Light* on *Bodies* by heating them, and putting their Parts into a vibrating Motion, wherein Heat principally conſiſts: for he obſerves, that all fix'd Bodies, when heated beyond a certain Degree, do emit *Light*, and ſhine; which ſhining, *&c.* appears to be owing to the vibrating Motion of the Parts; and all Bodies abounding in earthy and ſulphureous Particles, if they be ſufficiently agitated, emit *Light*, which way ſoever the Agitation be effected.

The ſame great Author obſerves, That there are but three Affections of *Light* wherein the Rays differ, *viz. Refrangibility*, *Reflexibility*, and *Colour*; and thoſe Rays which agree in *Refrangibility*, agree alſo in the other two, whence they may be well defin'd homogeneal: Again, the Colours exhibited by homogeneal *Light*, he calls homogeneal Colours; and thoſe produc'd by heterogeneal *Light*, heterogeneal Colours. From which Definitions he advances ſeveral Propoſitions:

1. That the Sun's *Light* conſiſts of Rays differing by indefinite Degrees of *Refrangibility*.
2. That Rays, which differ in *Refrangibility*, when parted from one another, do proportionably differ in the Colours which they exhibit.
3. That there are as many ſimple and homogeneal Colours, as there are Degrees of *Refrangibility*; for to every Degree of *Refrangibility* belongs a different Colour.
4. *Whiteneſs*, in all reſpects, like that of the Sun's immediate *Light*, and of all the uſual Objects of our Senſes, cannot be compounded of ſimple Colours, without an indefinite Variety of them; for to ſuch a Compoſition there are requir'd Rays endu'd with all the indefinite Degrees of *Refrangibility*, which infer as many ſimple Colours.
5. The Rays of *Light* do not act one on another in paſſing through the ſame Medium.
6. The Rays of *Light* do not ſuffer any Alteration of their Qualities from Refraction, nor from the adjacent quieſcent Medium.

7. There can be no homogeneal Colours produc'd out of *Light* by Refraction, which are not commix'd in it before ; ſince Refraction changes not the Qualities of the Rays, but only ſeparates thoſe that have divers Qualities by means of their different *Refrangibility*.

8. The Sun's *Light* is an Aggregate of homogeneal Colours ; whence homogeneal Colours may be call'd Primitive or Original.

Hence proceeds the whole Theory of Colours in Plants and Flowers.

Thoſe Parts, *v. g.* which are the moſt refrangible, conſtitute Violet Colour, the dimmeſt and moſt languid of all Colours.

And, on the contrary, thoſe Particles that are the leaſt refrangible, conſtitute a Ray of a *red* Colour, which is the brighteſt and moſt vivid of all Colours: The other Particles being diſtinguiſh'd into little Rays, according to their reſpective Magnitudes and Degrees of *Refrangibility*, excite intermediate Vibrations, and ſo occaſion the Senſations of the intermediate Colours. See Sir *Iſaac Newton*'s *Doctrine of Colours*.

Perhaps theſe Obſervations on *Light* may to ſome Perſons ſeem foreign to the ſubject Matter of this Book, yet, if thoroughly underſtood, might probably be found very uſeful. That learned and curious Inquirer into the Buſineſs of *Vegetation*, the Reverend Dr. *Hales*, in his Treatiſe on that Head, does upon the Query put by Sir *Iſaac Newton* [" *Are not* " *groſs Bodies and* Light *convertible into one another* ? *And may* " *not Bodies receive much of their Activity from the Particles of* " Light *which enter their Compoſition* ? *The Change of Bodies* " *into* Light, *and of* Light *into Bodies, is very conformable to* " *to the Courſe of Nature, which ſeems delighted with Tranſ-* " *mutations*"] add this Query ; " *And may not* Light *alſo, by* " *freely entring the expanded Surfaces of Leaves and Flowers,* " *contribute much to the ennobling the Principles of Vegeta-* " *bles* ?

LIGUSTICUM, [takes it Name of *Liguria*, becauſe this Plant, in old time, grew in greateſt Plenty near a River of *Genoa*, call'd *Liguria*] Lovage.

The *Characters* are ;

The Lobes of the Leaves are cut about their Borders, like thoſe of Parſley ; *the Flowers conſiſt, for the moſt part, of five Leaves, which expand in form of a* Roſe ; *each of theſe Flowers are ſucceeded by two oblong, gibboſe, furrow'd Seeds, which on one Side have a leafy Border*.

The *Species* are ;

1. LIGUSTICUM *vulgare, foliis apii. J. B.* Common Lovage.

2. LIGUSTICUM *Scoticum, apii folio. Tourn.* Scotch Lovage, with a Parſley Leaf.

3. LIGUSTICUM *Græcum, apii folio. T. Cor.* Greek Lovage, with a Parſley Leaf.

The firſt of theſe Plants is often us'd in Medicine, and was formerly reckon'd amongſt the Kitchen Herbs, but is now almoſt intirely caſt out of the Kitchen-Garden, and only cultivated for Phyſical Uſes : This Plant may be eaſily propagated by ſowing the Seeds, ſoon after they are ripe, in a moiſt Spot of Ground ; and when the Plants come up the Spring following, they ſhould be tranſplanted out to the Diſtance of eighteen Inches or two Feet aſunder, in a moiſt Soil ; where, if they are kept clear from Weeds, they will thrive exceedingly, and the ſecond Summer will produce Seeds: But the Herb may be frequently cut for Uſe ; their Roots abiding ſeveral Years do ſhoot again continually after being cut ; ſo that a few Plants will be ſufficient for the Uſe of a Family.

The ſecond and third Sorts are only preſerv'd in Collections of Plants for Variety, but are not in any Uſe at preſent. Theſe may be propagated in the ſame Manner as the former.

LIGUSTRUM, the Privet.

The *Characters* are ;

The Leaves grow by Pairs oppoſite to each other ; *the Flower conſiſts of one Leaf, is tubulous, and divided at the Top into five Segments* ; *the Ovary in the Centre of the Flower-cup becomes a globular ſoft Fruit, full of Juice, in which are lodg'd four Seeds*.

The *Species* are ;

1. LIGUSTRUM *vulgare. Park. Theat.* The common Privet.

2. LIGUSTRUM *foliis majoribus & magis acuminatis, toto anno folia retinens. Pluk. Alm.* The Ever-green Privet.

3. LIGUSTRUM *foliis e luteo variegatis. H. R. Par.* The yellow blotch'd Privet.

4. LIGUSTRUM *foliis argentatis. Breyn. Prod.* The Silver-ſtrip'd Privet.

5. LIGUSTRUM *Capenſe ſempervirens, folio craſſo ſubrotundo. Hort. Elth.* Evergreen Privet of the *Cape of Good Hope*, with a thick roundiſh Leaf.

6. LIGUSTRUM *Ægyptiacum, Alhenna vel Alcanna Arabum. Jeſſ. Egyptian* Privet, called Alhenna or Alcanna by the Arabians.

7. LIGUSTROIDES, *quod Liguſtrum Americanum aculeatum, fructu teſticulato. Plum.* Prickly American Privet, with teſticulated Fruit.

The firſt of theſe Plants is very common in moſt Parts of *England*, and is ſeldom cultivated in Gardens, unleſs for Variety : It commonly grows about eight or ten Feet high, in form of a Shrub, but may, by Art, be train'd up to a much greater Height, and may be intermix'd amongſt other Trees of low Growth in Wilderneſſes.

The ſecond Sort will grow much larger than the firſt, and is equally hardy : The Leaves of this commonly remain upon the Tree until the Spring before they decay, unleſs in very hard Winters ; for which Reaſon, it is more eſteem'd than the common Sort.

Theſe Plants are eaſily propagated by laying down their tender Shoots in Autumn, which in one Year's time will be rooted enough to tranſplant ; when they may be remov'd to the Places where they are deſign'd to remain, or planted in a Nurſery for two or three Years ; where they may be train'd for the Purpoſes deſign'd.

Formerly theſe Plants were greatly in Uſe for Hedges, but ſince ſo many others of greater Beauty have been introduc'd, which are much preferable to theſe for ſuch Purpoſes, they have been intirely rejected, the Trouble in keeping them in Order being very great, nor are the Hedges made with them ever ſo thick and handſome, as thoſe made with divers other Plants.

The two variegated Kinds are pretty Varieties amongſt other ſtriped Shrubs: Theſe may be propagated by budding or inarching them upon the plain Sort, as alſo by laying down their Branches ; but as they ſeldom ſhoot ſo faſt, as to produce many Branches proper for Layers, ſo the other Method is chiefly us'd. The Silver-ſtrip'd Sort is ſomewhat tenderer than the Plain, but will endure the open Air, if planted in a dry Soil, and in a warm Situation ; but if either of the variegated Kinds be planted in a moiſt, rich Soil, they are ſubject to become plain from their vigorous Growth.

The fifth Sort is a Native of the *Cape of Good Hope*, from whence it was brought into the Gardens in *Holland*, where it hath been propagated and communicated to ſeveral Parts of *Europe*. This Plant is pretty hardy, ſo may be preſerved in a common Green-houſe, with *Oranges*, *Myrtles*, &c. Where it will make an agreeable Variety. It may be propagated by laying down the tender Shoots, which will take Root in one Year, and may then be tranſplanted into ſmall Pots filled with freſh light Earth, obſerving to water and ſhade them until they have taken new Root ; after which Time, they may be treated in the ſame Manner as *Myrtles*, or any other hardy Exotic Plant, which requires to be houſed in Winter.

The Sixth Sort grows plentifully in *Egypt*, and ſome other Places in the *Eaſt*, from whence the Seeds have been ſent to *Europe*, and many of the Plants have been raiſed, which proved ſo tender, that few of them have been preſerved : The Leaves of this Tree dried and powdered, are a great Merchandiſe throughout the *Turkiſh* Empire, and the neighbouring Countries, where it is uſed to dye the Hair and Nails of the Inhabitants of a yellow Colour.

This Sort may be propagated by Seeds, which ſhould be ſown early in the Spring on a Hot-bed ; and when the Plants are come up, they ſhould be tranſplanted into ſeparate ſmall Pots filled with freſh rich Earth, and plunged into a Hot-bed of Tanners-bark, where they muſt be treated after the ſame Manner as the young *Coffee-Trees*, and muſt be conſtantly preſerved in the Stove ; for they are too tender to thrive in the open Air in this Climate, even in the warmeſt Seaſon of the Year.

The ſeventh Sort was diſcovered by Father *Plumier* in *America* ; the Seeds of this Plant were ſent into *England* by the late Dr. *William Houſtoun*, who gathered them at *Campechy*. This Sort is tender, and requires to be preſerved in Stoves, during the winter Seaſon ; otherwiſe it will not live in this Country.

This Sort will grow to the Height of ten or twelve Feet in this Country, and is more hardy than the former; ſo will thrive in the open Air during the Summer-months, provided it is placed in a warm Situation; and in Winter it may be placed in a Stove with Plants, which require only a moderate Warmth to preſerve them. This Plant muſt be frequently watered; for it grows naturally on moiſt ſwampy Soils, near the Sea. Theſe may be both propagated by laying down their Branches in the Spring, which if duly watered, will be rooted by the next Spring, when they may be taken off, and tranſplanted into Pots filled with light freſh Earth, and then plunged into a moderate Hot-bed of Tanners-bark, which will greatly promote their taking new Root; but they muſt be watered and ſhaded, until they are rooted; then they may be treated in the ſame manner as the old Plants.

LILAC, [it is an *Arabick* Name, tho' ſome derive it from the *Lily*, becauſe its Flowers bear ſome Reſemblance to the *Lily*: It is alſo call'd by the *Greeks* Σύριγξ, and by the *Latins*, *Syringa*, becauſe when the Pith is taken out of its thick Branches, they are made into Pipes] The Pipe-Tree.

The *Characters* are;

The Flowers conſiſt of one Leaf, are Funnel-ſhap'd, but divided at Top into five Segments, and are collected into oblong ſpecious Spikes; the Flowers are ſucceeded by compreſs'd Pods, which are ſcarce an Inch long, and are divided into two Cells, in which are contain'd broad, flat Seeds, which are compreſs'd on their Edges.

The *Species* are;

1. LILAC *Matthioli*. The common Blue Lilac, or Pipe-Tree.
2. LILAC *flore albo. Tourn.* The white Lilac, or Pipe-Tree.
3. LILAC *flore ſaturate purpureo. Tourn.* The deep purple Lilac, or Pipe-Tree.
4. LILAC *flore albo, foliis ex luteo variegatis. Cat. Plant. Hort.* The Yellow-blotch'd Lilac.
5. LILAC *flore albo, foliis ex albo variegatis. Cat. Plant. Hort.* The White-blotch'd Lilac.
6. LILAC *folio liguſtri. Tourn.* Lilac with Privet Leaves, *falſely called*, The *Perſian* Jaſmine.
7. LILAC *laciniato folio. Tourn.* Lilac with cut Leaves, *falſely called*, The Cut-leav'd *Perſian* Jaſmine.

The three firſt Sorts do commonly grow eighteen or twenty Feet high, and are very great Ornaments to Quarters of flowering Trees in the Spring during their flowering Seaſon, if rightly diſpos'd amongſt Trees of the ſame Growth. The firſt and ſecond Sorts are more common than the third; but the third is much preferable to the ſecond: The Flowers of that growing much cloſer upon the Bunches, and are of a finer Purple Colour, and the Trees generally produce them in greater Quantities; ſo that this, and the white Sort, being regularly intermix'd, do afford an agreeable Variety, tho' the ſecond may be admitted to add a Luſtre to the other.

Theſe Plants are eaſily propagated by Suckers, which they ſend forth in great Plenty from the old Plants: Theſe ſhould be taken off in *October*, and planted into a Nurſery, where they may remain three or four Years; after which Time they will be fit to tranſplant into the Wilderneſs, where they are to continue: They will require no other Culture than to dig the Ground about them every Year, and take off the Suckers which are produc'd from their Roots; which, if ſuffer'd to remain, would ſtarve the old Plants, and grow up into an irregular Thicket.

They will grow in almoſt any Soil or Situation, but do commonly flower beſt in that which is dry; for tho' a ſtrong, moiſt Soil will cauſe them to grow more vigorouſly, yet they are ſeldom ſo productive of Flowers as in a dry Soil, which is generally the Caſe with moſt other Plants.

The two variegated Sorts are preſerv'd by ſome Perſons, who delight in ſtrip'd Plants, as Curioſities, but they have no great Beauty in them; for in the Summer-time, when theſe Plants are free of Growth, their white and yellow Blotches do not appear very plain: And when they do, it appears more like a Diſtemper in them, than any real Beauty. Theſe may be propagated by budding or inarching them upon the common Sort.

The Privet-leav'd Lilacs are of humbler Growth than thoſe before-mention'd, ſeldom riſing above ſix or ſeven Feet high, but are very great Ornaments in ſmall Wilderneſs-Quarters of flowering Shrubs, where being intermix'd with other Shrubs, of the ſame Growth, they afford an agreeable Proſpect. Theſe produce their Flowers in much longer and ſlenderer Bunches than the other Sorts, and have a more agreeable Scent.

They may be propagated from Suckers as the former; but as they ſeldom produce them in ſuch Plenty, ſo the moſt expeditious Method is, to propagate them by Layers, which will take Root in one Year fit to tranſplant; and the Plants thus rais'd, will be much better rooted than thoſe produc'd by Suckers, and are not ſo ſubject to ſend forth Suckers from their Roots.

The Cut-leav'd Sort differs from the other in no other reſpect but in having its older Leaves deeply cut in: They are both very hardy, and will grow in almoſt any Soil or Situation, and may be train'd up to regular Heads, if rightly manag'd while young.

LILIO-ASPHODELUS; [ſo call'd, becauſe this Plant partakes both of the *Lily* and *Daffodil*] The Aſphodel or Day Lily.

The *Characters* are;

It hath a Root like Aſphodel *(or* Kingſpear); *the Flower conſiſts of one Leaf, which is deeply cut into ſix Segments, and expands in Form of a* Lily; *the Flower is ſucceeded by an oval Fruit, which contains ſeveral roundiſh Seeds.*

The *Species* are;

1. LILIO-ASPHODELUS *luteus. Park. Par.* The Yellow Day Lily.
2. LILIO-ASPHODELUS *puniceus. Park. Par.* The Red Day Lily.
3. LILIO-ASPHODELUS *Americanus ſempervirens maximus polyanthos albus. Hort. Elth.* Greateſt ever-green *American* Aſphodel-Lily, with many white Flowers.
4. LILIO-ASPHODELUS *luteus minor. Inſt. R. H.* The leſſer yellow Aſphodel-Lily.
5. LILIO-ASPHODELUS *Phœniceus minor. Inſt. R. H.* The leſſer red Aſphodel-Lily.
6. LILIO-ASPHODELUS *Americanus, flore umbellato albo, coſtâ purpureâ notato. Plum. Cat. American* Aſphodel-Lily, with white Flowers growing in an Umbel, and a Stalk marked with Purple.
7. LILIO-ASPHODELUS *Americanus, foliis ſcillæ, flore umbellato maximo purpureo. Plum. Cat. American* Aſphodel-Lily, with Leaves like the Squill, and large purple Flowers growing in an Umbel.
8. LILIO-ASPHODELUS *Americanus bifolius, flore ſingulari purpureo. Plum. Cat. American* Lily-Aſphodel, with two Leaves, and a ſingle purple Flower.

The firſt two Plants are very common in moſt of the old *Engliſh* Gardens, the firſt is often call'd by the Gardeners, the *Yellow Tuberoſe*, from its having a very agreeable Scent; but the other is called the *Day Lily*, or the *Tuberoſe Orange Lily*, in moſt Places.

They are both very hardy Plants, and will multiply exceedingly, if ſuffered to remain two or three Years undiſturbed, eſpecially the red Sort, which ſends forth great Quantities of Off-ſets from the old Plants, by which they may be eaſily propagated: The beſt Time to tranſplant their Roots is in *September* or *October*, after their Leaves are decay'd, (tho' they may be removed at almoſt any Time, provided they are taken up with Care, and not kept too long above Ground): They are proper for large Borders in a Pleaſure-Garden, or to plant under Trees in Avenues, where they will thrive and flower very well; but they are too large for ſmall Flower Gardens, and afford Harbour for Snails and other Vermin, for which Reaſon they ſhould not be admitted too near choicer Plants.

They will grow in almoſt any Soil or Situation; the yellow Sort produces its Flowers in *May* and *June*, and the red Sort comes about a Month later; their Flowers are of a ſhort Duration, ſeldom continuing above two Days, but are ſucceeded by freſh Flowers for near a Month ſucceſſively; but the yellow Sort commonly continues longer in Flower than the other, and the Flowers are ſmaller, and of longer Duration.

The third, ſixth, ſeventh, and eighth Sorts are Natives of the warm Parts of *America*; ſo muſt be preſerved in Stoves, otherwiſe they will not live thro' the Winter in this Country. Theſe may be propagated very eaſily, for their Roots creep under Ground, and ſend forth many new Plants at a Diſtance from the old Root, which ſhould be taken off in the Spring, and each Plant put into a pretty large ſeparate Pot, filled with rich light Earth, and then plunged into a moderate Hot-bed of Tanners-bark, to forward their taking new Root: They muſt alſo be frequently refreſhed with Water, but it muſt not be given in large Quantities, eſpecially until they have taken good Root, leſt it ſhould rot the tender Fibres.

Theſe Plants thrive and produce their Flowers plentifully in *England*, when they are conſtantly kept plunged in the Bark-Stove,

ſtove; for the Fibres of the Roots will frequently creep thro' the Holes at the Bottom of the Pots, and ſtrike into the Bark, which is of great Service to the Plants. During the Winter Seaſon, when they are not very free in Growth, they ſhould not have too much Water; but in Summer they will require to have Plenty of Water in hot Weather. When the Pots are filled with the Roots, they ſhould be taken out and divided to propagate them; the beſt Time for this is, when the Leaves are in the leaſt vigorous State, which is generally in *March*. When theſe Roots are parted, it ſhould be done with Care, ſo as not to break or bruiſe the larger Roots; for thoſe bruiſed are very ſubject to rot. Theſe Plants ſhould not be ſhifted out of the Pots too often, for that will prevent their flowering; for where the Roots are confined, (provided it be not too much) they will always flower moſt freely; ſo that they need not be tranſplanted oftener than once every Year.

In Summer, when the Weather is hot, theſe Plants ſhould have a large Share of free Air, by opening of the Glaſſes of the Stove; but they ſhould never be placed abroad in the open Air, for they are too tender to thrive abroad in this Climate in the warmeſt Seaſons. Theſe Plants uſually flower in *June July*, and *Auguſt*, tho' ſometimes they will flower both earlier and later in the Year: And when they are in Flower, they afford an agreeable Scent, and make a fine Appearance.

The fourth and fifth Sorts are very hardy Plants, which will thrive in almoſt any Soil or Situation, and do greatly increaſe by their Roots. Theſe are to be managed in the ſame Manner as the two firſt Sorts.

LILIO-FRITILLARIA. *Vide* Fritillaria.

LILIO-HYACINTHUS, Lily-Hyacinth.

The *Characters* are;

It hath a Lily Flower, which is compoſed of ſix Leaves, and ſhaped like the Flower of Hyacinth; whoſe Pointal afterward becomes a globular pointed Fruit, for the moſt part three-corner'd, and divided into three Cells, in which are contain'd many Seeds, which are almoſt round. To theſe Notes muſt be added, the Roots, which are ſcaly, and ſhap'd like thoſe of the Lily.

The *Species* are;

1. LILIO-HYACINTHUS *vulgaris, flore cœruleo. Inſt. R. H.* Common Lily-Hyacinth, with a blue Flower.
2. LILIO-HYACINTHUS *vulgaris, flore niveo. Inſt. R. H.* Common Lily-Hyacinth, with a Snow-white Flower.
3. LILIO-HYACINTHUS *vulgaris, flore rubello. Inſt. R. H.* Common Lily-Hyacinth with a red Flower.

Theſe Plants are propagated by Off-ſets from their Roots, in the ſame Manner as *Lilies* and *Crown Imperials*; the beſt Time to take up their Roots is in *July*, ſoon after the Leaves are decayed. Theſe Roots may be dried in a ſhady Place, and kept out of the Ground till *Michaelmas*; when they ſhould be planted in the Borders of the Flower-Garden, amongſt other hardy bulbous and tuberoſe-rooted Flowers, where they will make a pretty Diverſity the following Spring, when they are in Flower.

They will thrive in almoſt any Soil, which is not over-moiſt, or too ſtrong Clay, and in almoſt any Situation which is open, and not ſhaded by Trees. The Roots ſhould be planted four or five Inches deep, and where they are planted in a Bed by themſelves, ſhould be placed about a Foot Diſtance from each other: But as they are very hardy, and do not require any Covering, ſo they are very proper for adorning the large Borders of the Flower-Garden.

The Roots may remain in the Ground undiſturbed two or three Years, which is the better Method to obtain a large Increaſe of their Roots, than if they are removed every Year. When the Roots are taken up and dried, the Off-ſets ſhould be intirely ſeparated from the old Roots; and thoſe which are ſmall, muſt be ſoon planted again in a Nurſery-bed at about five or ſix Inches Diſtance, where they may remain for a Year or two, until they have acquired Strength to flower; when they may be tranſplanted into the Boders of the Flower-Garden. The Off-ſets being ſmall, muſt never remain long out of the Ground, becauſe they are ſubject to ſhrivel, and then, if they are planted, and there ſhould happen much Rain ſoon after, they will periſh. Theſe Plants flower the latter End of *April*, or the Beginning of *May*, when they make a pretty Appearance, their Flowers being in Shape like the *Starry Hyacinth*.

Theſe Plants may alſo be propagated by Seeds, which ſhould be ſown in Pots or Caſes filled with freſh light Earth, ſoon after they are ripe; and muſt be treated in the ſame Manner as hath been directed for the *Lilies* and *Martagons*. The Plants raiſed from Seeds will not flower, until they are four or five Years old, which diſcourages moſt People attempting to propagate them by that Method; tho', if it was more practiſed, there might be a greater Variety of theſe Flowers, than are at preſent to be found, ſince it was by this Method that the great Variety of curious Flowers now in being were obtained.

LILIO-NARCISSUS, [is ſo call'd, becauſe it reſembles both theſe Plants] Lily-Daffodil.

The *Characters* are;

It hath a coated, bulbous Root; the Flower is ſhap'd like a Lily, conſiſting of ſix Leaves, and is cover'd with a membranaceous Sheath like the Narciſſus; *the Fruit ſucceeds the Flower in the ſame Form of the* Narciſſus, *is oblong or roundiſh, and divided into three Cells, which are fill'd with roundiſh Seeds.*

The *Species* are;

1. LILIO-NARCISSUS *Indicus, ſaturato colore, purpuraſcens. Mor. Hiſt.* The Lily-Daffodil, of a deep Purple-colour.
2. LILIO-NARCISSUS *Indicus, flore albo, exterius rubente. Tourn. Indian* Lily-Daffodil, with a white Flower, which is reddiſh on the Outſide.
3. LILIO-NARCISSUS *polyanthus, flore incarnato, fundo ex luteo albeſcente. Sloan. Cat.* Many-flower'd Lily-Daffodil, with a Carnation Flower, having a whitiſh yellow Bottom, commonly called in the *Weſt-Indies*, *Red Lily*.
4. LILIO-NARCISSUS *Japonicus, rutilo flore. Mor. Hiſt.* The *Japan* Lily-Daffodil, commonly called the *Guernſey* Lily.
5. LILIO-NARCISSUS *folio latiſſimo, floribus niveis inodoris. Tourn.* Lily-Daffodil, with a very broad Leaf and ſnowy Flowers without Scent.
6. LILIO-NARCISSUS *Indicus, Narciſſus Liliflorus, aureus, ſtriis argenteis pictus, floribus amplis, cernuis gemellis, caule magno cepæ fiſtuloſo. Pluk. Phyſ. Indian* Lily-Daffodil, with ample Gold-colour'd Flowers ſpotted with Silver, and a large hollow Stalk.
7. LILIO-NARCISSUS *Indicus, flore incarnato, lineis albis ſtriato, odorato. Indian* Lily-Daffodil, with a Carnation Flower ſtrip'd with white Lines, and of a ſweet Scent, commonly called the Bella-donna Lily.
8. LILIO-NARCISSUS *luteus autumnalis minor. Tourn.* The leſſer yellow Autumnal Lily-Daffodil, commonly called the Autumnal Narciſſus.
9. LILIO-NARCISSUS *Jacobæus latifolius Indicus, rubro flore. Mor. Hiſt.* Broad-leav'd *Indian* Lily-Daffodil, with a red Flower.
10. LILIO-NARCISSUS *Indicus maximus ſphæricus, floribus plurimis rubris liliaceis. Mor. Hiſt.* Greateſt *Indian* Lily-Daffodil, with many Lily-ſhap'd ſpherical Flowers.
11. LILIO-NARCISSUS *Indicus pumilus polyanthos. Mor. Hiſt.* Dwarf *Indian* Lily-Daffodil, with many Flowers.
12. LILIO-NARCISSUS *Zeylanicus latifolius, flore niveo externè lineâ purpureâ ſtriato.* Broad-leav'd Lily-Daffodil of *Ceylon*, with a ſnow-white Flower, ſtriped with purple Lines on the Out-ſide.
13. LILIO-NARCISSUS *Indicus pumilus monanthos albus. Mor. Hiſt.* Dwarf *Indian* Lily-Daffodil, with one white Flower.
14. LILIO-NARCISSUS *luteus vernus. Inſt. R. H.* Yellow Spring Lily-Daffodil.
15. LILIO-NARCISSUS *luteus autumnalis major. Inſt. R. H.* Greater yellow autumnal Lily-Daffodil, commonly called Autumnal Narciſſus.
16. LILIO-NARCISSUS *luteus multiplex autumnalis. Inſt. R. H.* Autumnal yellow Lily-Daffodil, with double Flowers.
17. LILIO-NARCISSUS *Bæticus, luteus minor odoratiſſimus. Inſt. R. H.* Leſſer yellow Lily-Daffodil of *Bætica*, with very ſweet Flowers.

The firſt of theſe Plants is very rare at preſent in *England*; but in *Italy* it is very common, eſpecially about *Florence*, where they bring large Bunches of the Flowers into the Market, and ſell them for Flower-Pots, by the Name of *Narciſſus Belladonna*; and is probably one of the firſt Sorts of this Flower which was brought into *Europe*. This Plant thrives ſo well in *Italy*, as to need no other Culture than the common *Lily*; and altho' it does not flower until *Auguſt*, yet it commonly produces good Seeds in that Countay, from which they propagate them in great Plenty; but with us they require to be planted in Pots fill'd with light freſh Earth, and in Winter they muſt be ſhelter'd to prevent their Leaves being deſtroy'd by the Froſt, which if it does not quite kill their Roots, will ſo weaken them, as that they will not recover Strength to flower in ſeveral Years after, tho' you ſhould attend them with ever ſo much Care. This Plant produces its Flowers in *September*, and the Green Leaves come up ſoon after, and abide all the Winter and Spring until *May*, at which Time they decay, ſoon after which the Roots ſhould be tranſplanted; for if they are let ſtand till *July*, they will have ſent forth new Fibres, when it will greatly injure the Roots if they are diſturb'd.

The ſecond Sort is leſs common in *England* than the firſt; this ſeldom produces more than one Flower upon each Stalk, which is ſmaller than thoſe of the former; but nearly of the ſame Figure; this is alſo cultivated as the former, and flowers about the ſame Seaſon.

The third Sort is very common in *Barbadoes*, St. *Chriſtopher's*, and the other warm Iſlands of the *Weſt-Indies*; but at preſent it is very rare in *England*: This Sort is much tenderer than either of the former, and will require to be kept in a Hot-bed of Tanners-bark, in order to produce Flowers. The Roots of this Plant may be very eaſily brought from the *Weſt-Indies*, if they are taken up immediately after their Leaves decay, and ſent over in a Box dry; for if they are planted in Tubs of Earth, they generally rot in their Paſſage, by receiving too great Quantities of Water.

The fourth Sort is ſuppos'd to come originally from *Japan*, but has been many Years cultivated in the Gardens of *Guernſey* and *Jerſey*; in both which Places they ſeem to thrive as well as if it was their native Country; and from thoſe Iſlands their Roots are ſent annually to the Curious in moſt Parts of *Europe*, and are commonly call'd *Guernſey Lilies*; the Roots of this Plant are generally brought over in *July* and *Auguſt*, but the ſooner they are taken out of the Ground after their Leaves decay, they are the better: For altho' the Roots which are taken up when their Flower-ſtems begin to appear, will flower, yet their Flowers will not be ſo large, nor will their Roots be near ſo good after, as thoſe which were removed before they had ſent out freſh Fibres.

When theſe Roots come over, they ſhould be planted in Pots filled with freſh, light, ſandy Earth, mix'd with a little very rotten Dung, and placed in a warm Situation, obſerving now and then to refreſh the Earth with Water; but by no means let them have too much Wet, which would rot their Roots, eſpecially before they come up: About the Middle of *Auguſt*, ſuch of the Roots as are ſtrong enough to flower, will begin to ſhew the Bud of their Flower-ſtem, (which is commonly of a red Colour); therefore you ſhould remove theſe Pots into a Situation where they may have the full Benefit of the Sun, and may ſhelter'd from ſtrong Winds; but by no means place them too near a Wall, nor under Glaſſes, which would draw them up weak, and render them leſs beautiful: At this Seaſon they ſhould be gently refreſh'd with Water, if the Weather be warm and dry; but if it ſhould prove very very wet, they ſhould be ſcreen'd from it.

When the Flowers begin to open, the Pots ſhould be removed under Shelter, to prevent the Flowers from being injured by too much Wet; but they muſt not be kept too cloſe, nor placed in a Situation too warm, which would occaſion their Colour to be leſs lively, and haſten their Decay. The Flowers of this Plant will continue in Beauty (if rightly manag'd) a full Month, and tho' they have no Scent, yet for the Richneſs of their Colour, they are juſtly eſteem'd in the firſt Rank of the flowery Race.

After the Flowers are decay'd, the Green Leaves will begin to ſhoot forth in Length, and if ſhelter'd from ſevere Cold, will continue growing all the Winter; but they muſt have as much free Air as poſſible in mild Weather, and be cover'd only in great Rains or Froſts, for which Purpoſe a common Hot-bed Frame is the propereſt Shelter for them, under which if they are placed, the Glaſſes may be taken off conſtantly every Day in dry open Weather, which will encourage the Leaves to grow ſtrong and broad; whereas when they are placed in a Green-houſe, or not expoſed to the open Air, they will grow long and ſlender, and have a pale, weak Aſpect, whereby the Roots will become weak, ſo that it ſeldom happens that they produce Flowers under ſuch Management.

Theſe Roots ſhould be tranſplanted every other Year toward the latter End of *June*, or the Beginning of *July*, and planted into freſh Earth (but they ſhould not be oftener removed, for that would retard their Flowering). The Off-ſets ſhould alſo be taken off and planted into ſeparate Pots, which in three Years Time will produce Flowers, ſo that after a Perſon is once ſtock'd with theſe Roots, they may increaſe them, ſo as to have a Supply of blowing Roots, without being at the Trouble or Expence of ſending to *Guernſey* every Year for freſh Roots; and the Roots preſerved here, will flower ſtronger than thoſe which are uſually brought from thence, for the Inhabitants of thoſe Iſlands are not very curious in cultivating theſe Roots: Their uſual Method is to plant them at a great Diſtance in a Bed of common Earth, where they let them remain for many Years, in which Time they produce ſuch a Number of Off-ſets, that many times one ſingle Cluſter has contain'd above a hundred Roots; by which means thoſe which grow on the Inſide, are ſo much compreſſed by the outer Roots, that they are perfectly flatted, and from the Number of Roots they are all rendered weak, and ſo unfit to produce ſuch large Stems of Flowers, as thoſe which have grown ſingle and are of a ſpherical Figure.

But when a Perſon has got a large Number of theſe Roots, it will be troubleſome to preſerve them in Pots; therefore you ſhould prepare a Bed of the following Earth, in ſome well-ſhelter'd Part of the Garden, *viz.* Take a third Part of freſh Virgin Earth upon a Paſture Ground, which is light; then put near an equal Part of Sea Sand, to which you ſhould add rotten Dung and ſifted Lime-rubbiſh of each an equal Quantity: With this Earth (when well mix'd and incorporated) you ſhould make your Bed about a Foot thick, raiſing it about four or five Inches above the Surface of the Ground, if the Situation be dry; but if the Ground be wet, you ſhould raiſe it eight or nine Inches higher: In this Bed about the Beginning of *July* (as was before directed) you ſhould plant the Roots about ſix Inches aſunder each Way; and in the Winter, when the Froſt begins, you ſhould either cover the Bed with a Frame, or arch it over and cover it with Mats and Straw, to prevent their Leaves from being pinch'd with Cold; but in the Summer the Covering may be intirely removed, and the Bed kept conſtantly clear from Weeds, obſerving to ſtir the Surface of the Earth now and then; and every Year when the Leaves are decay'd, you ſhould ſift a little freſh Earth over the Bed, to encourage the Roots. In this Bed the Roots may remain until they are ſtrong enough to produce Flowers, when they may be taken up and planted into Pots, as was before directed, or ſuffered to remain in the ſame Bed to flower.

The Roots of theſe Plants do not flower again the ſucceeding Year (as in many other Sorts of Bulbs); but if their Bulbs contain two Buds in their Center, as is often the Caſe, they very often flower twice within the Compaſs of three Years, after which the ſame individual Root does not flower again in ſeveral Years, but only the Off-ſets from it.

The fifth Sort is at preſent very rare in *England*, and only to be found in ſome very curious Garden; this is much tenderer than the laſt, and requires to be managed as was directed for the third Sort, with which Management it will thrive exceeding well; but you muſt obſerve never to water theſe Roots after their Leaves are decay'd (which is ſoon after *Chriſtmas*) until they ſhoot out again in *April*, for Moiſture at that Seaſon, while they are in an unactive State, is very ſubject to rot them: This Plant produces its Flowers commonly in *March*, and the green Leaves appear ſoon after.

The ſixth Sort is alſo tender, and requires to be kept in a warm Stove in Winter; but in the Summer-ſeaſon it will bear to be expos'd to the open Air, in warm, dry Weather; this Sort ſhould be treated in the ſame Manner as the laſt, with this Difference only, that it may be preſerved without being plung'd in Tanners Bark: This Plant produces its Flowers nearly about the ſame Time with the laſt; but the Flowers of this are much more beautiful.

The ſeventh Sort was brought from *Portugal*, where they are in great Plenty, and is by the Inhabitants call'd *Bella-donna*; but this is a very different Plant from that which the *Italians* call by that Name, the Flowers of this Kind being larger and paler colour'd than thoſe of the *Italian* Sort, and ſeldom have more than three or four upon one Stem, whereas the other has often ten or twelve. This Plant is propagated in the ſame manner as was directed for the *Guernſey* Lily (to which I refer the Reader, to avoid Repetition); the Flowers of this Plant are always produced about the ſame Time as the *Guernſey* Lily, but are not near ſo beautiful.

Theſe Plants do not increaſe very faſt in our Climate, for which Reaſon a curious Perſon ſhould be furniſhed with ſeveral Roots of each Kind from Abroad, in order to have ſome Flowers every Year, for they ſeldom blow two Years together, (as was before obſerved) nor does the ſame Root flower more than twice, which is commonly within three Years; ſo that where there are not ſix or eight Roots of each Sort, it can't be expected to have Flowers very often, notwithſtanding no Art or Care be wanting in their Culture; for in their native Countries they are not conſtant Flowerers.

The eighth Sort is a very hardy Plant, and increaſes very faſt from Off-ſets: The Seaſon for tranſplanting theſe Roots, is any Time from *May* to *July*, after which it will be too late to remove them, for they will begin to puſh out new Fibres by the Middle of that Month, if the Seaſon be moiſt, and many times they flower in *Auguſt*; ſo that if they are then tranſplanted it will ſpoil their flowering: This Plant will grow in almoſt any Soil or Situation, but it will thrive beſt in a freſh, light, dry Soil, or in an open Situation, *i. e.* not under the Dripping of Trees, nor too near to Walls. It is commonly called by the Gardeners the *Yellow Autumnal Narciſſus*, &c. and is uſually ſold by them with *Colchicums*, for Autumnal Ornaments to Gardens, for which Purpoſe this is a very pretty Plant.

The ninth, tenth, eleventh and twelfth Sorts are very tender Plants, ſo require to be placed in a warm Stove, otherwiſe they will not abide the Winter in this Climate; theſe are propagated by Off-ſets from their Roots, becauſe they rarely produce good Seeds in *Europe*. The beſt Time to tranſplant the Roots, and to take the Off-ſets from them, is in the Spring, before they put out new Leaves. Theſe Roots ſhould be planted in Pots filled with freſh light ſandy Earth, and then plunged into a moderate Hot-bed of Tanners Bark, obſerving to refreſh them gently in warm Weather; but they ſhould not have too much Moiſture, for that will rot the Roots, eſpecially when they are newly tranſplanted, or at a Seaſon when they are not in Action. The beſt Method to increaſe the Roots, and to have them flower ſtrong and conſtantly, is to keep the Pots conſtantly plunged in the Bark-bed in the Stove; for when they are placed on Benches in the Stove, the extreme Fibres of the Roots, which are at the Bottom and Sides of the Pots, are never well nouriſhed; ſo they do not produce their Flowers ſo conſtantly or ſtrong, as thoſe which are plunged. In hot Weather theſe Plants ſhould have a large Share of freſh Air, by opening of the Glaſſes of the Stove; but in cold Weather they muſt be kept warm, otherwiſe the Roots will decay. Theſe Plants do not flower regularly at any Seaſon of the Year; for ſometimes they will flower in the Spring, and at other Times late in the Summer, or in Autumn; ſo that the Time of tranſplanting of their Roots ſhould be varied according to the Time of their Flowering; for thoſe which flower in the Spring, commonly drop their Leaves about *Auguſt*, when it is a proper Time to tranſplant them; whereas thoſe which flower in Autumn, will not drop their Leaves until the Middle of Winter. Therefore theſe muſt not be removed until the Middle or latter End of *March*: ſo that, whenever their Leaves are decayed, and the Roots appear to be inactive, they may ſafely be tranſplanted, provided it be not in the Middle of Winter. Theſe Plants produce very beautiful Flowers, ſo are worthy of a Place in every good Stove, there being very few Exotick Plants, which make ſo fine an Appearance as theſe, when they are in Flower.

The thirteenth Sort is much more hardy than any of the former, but will not abide the Cold of our Winters in *England*, if planted in the open Air: ſo that this Sort ſhould be treated in the ſame Manner as hath been directed for the *Guernſey* and *Belladonna Lilies*. This Sort is alſo propagated by Off-ſets from the Roots, but it increaſes ſlowly in this Country.

The fourteenth, fifteenth, ſixteenth and ſeventeenth Sorts, will thrive in the open Air in this Country; but the fifteenth Sort is the only common Kind in *England*: The others are preſerved by ſome few People, who are curious in collecting uncommon Flowers. Theſe are all propagated by Off-ſets, for they ſeldom produce Seed in *England*. The beſt Time to tranſplant the Autumnal Kinds, is in *July*, when their Leaves are intirely decayed; but their Roots ſhould not be kept long out of the Ground; for they always begin to ſhoot out new Fibres in *Auguſt*, and in *September* they produce their Flowers; ſo that coming ſo late in the Seaſon, they are the more eſteemed, becauſe there are not a great Variety of more beautiful Flowers then in Perfection. Theſe Plants are of humble Growth, ſo are proper to intermix with *Colchicums*, *Autumnal Crocus's*, and *Cyclamens*, in ſome of the Borders of the Flower-Garden, where they will make a pretty Appearance for about a Month in the Autumn Seaſon.

They will thrive in almoſt any Soil or Situation, provided it be not too wet; for too great Moiſture in Winter, lying long near their Roots, will rot them, becauſe at that Seaſon they are in the greateſt Vigour; for after the Flowers are paſt, their green Leaves continue growing moſt Part of the Winter; and as the Warmth comes on in the Spring, ſo their Leaves decay.

The Sort which flowers in the Spring, ſhould not be tranſplanted ſo ſoon as the others; for the Leaves of this do not decay till toward the Middle of *July*, ſo that theſe Roots ſhould be tranſplanted in *Auguſt*. This requires an Eaſt or South-Eaſt Border; for if they are planted too much in the Shade, they will not flower ſo well, as when they have a more open or warm Situation. The Roots of all theſe Sorts ſhould remain untranſplanted two or three Years; for if they are removed every Year, they will not flower near ſo ſtrong, nor produce ſo great Increaſe, as when they remain undiſturbed: But then the Surface of the Borders in which they are planted, ſhould be cleaned from Weeds, and gently ſtirred, when the green Leaves are decayed, and a little freſh Earth ſpread over the Borders, which will greatly encourage the Roots, and cauſe them to flower ſtrong.

LILIUM, [takes its Name of λεῖος, *ſmooth, poliſhed*, becauſe its Leaves are, as it were, poliſhed; or of λείρον, which ſignifies the ſame Thing.] The Lily.

The *Characters* are;

It hath a bulbous Root, conſiſting of ſeveral fleſhy Scales adhering to an Axis; the Stalk is greatly furniſhed with Leaves; the Flower is compos'd of ſix Leaves, and is ſhap'd ſomewhat like a Bell; in ſome Species the Petals are greatly reflex'd, but in others but little; from the Centre of the Flower riſes the Pointal, which becomes an oblong Fruit, that is commonly triangular, divided into three Cells, and full of compreſs'd Seeds, which are border'd, lying upon each other in a double Row.

The *Species* are;

1. **Lilium** *album, flore erecto & vulgare. C. B. P.* Common white Lily.
2. **Lilium** *album inodorum, flore pleno. H. R. Par.* The double white Lily, without Smell.
3. **Lilium** *album, floribus dependentibus, ſive peregrinum. C. B. P.* The foreign white Lily, with hanging Flowers.
4. **Lilium** *album, lato caule, multiflorum. H. R. Par.* The white Lily, with broad flat Stalks, bearing many Flowers.
5. **Lilium** *album vulgare, foliis ad limbos flaveſcentibus. H. L.* Common white Lily, with ſtrip'd Leaves.
6. **Lilium** *album, flore lineis purpureis variegato. D. Marchant.* The white Lily, ſtrip'd with Purple.
7. **Lilium** *purpureo-croceum majus. C. B. P.* The common Orange Lily, *vulgo*.
8. **Lilium** *pumilum cruentum. Park. Par.* The dwarf red Lily.
9. **Lilium** *rubrum, multiplici flore. Park. Par.* The double red Lily.
10. **Lilium** *bulbiferum anguſtifolium. C. B. P.* Narrow-leav'd bulbiferous Lily, *commonly called* the Fiery Lily.
11. **Lilium** *floribus reflexis, montanum. C. B. P.* The Imperial Martagon.
12. **Lilium** *floribus reflexis albis punctatis. C. B. P.* The white ſpotted Martagon.
13. **Lilium** *floribus reflexis albis non punctatis. C. B. P.* The white Martagon, without Spots.
14. **Lilium** *floribus reflexis, montanum, flore pleno. H. R. Par.* The double flowering Martagon.
15. **Lilium** *flavum anguſtifolium, flore flavo, maculis nigris diſtincto. C. B. P.* The ſpotted *Canada* Martagon, *vulgo*.
16. **Lilium** *miniatum odorum anguſtifolium. C. B. P.* The ſcarlet Martagon of Pompony, *vulgo*.
17. **Lilium** *Byzantinum miniatum polyanthos. C. B. P.* The ſcarlet Martagon, with many Flowers.
18. **Lilium** *Byzantinum miniatum. C. B. P.* The common ſcarlet Martagon.
19. **Lilium** *Byzantinum, flore flavo. C. B. P.* The yellow Martagon of *Conſtantinople*.
20. **Lilium** *purpureo-croceum majus, foliis ex luteo eleganter variegatis.* The Orange Lily, with beautiful variegated Leaves.
21. **Lilium** *purpureum minus, flore pleno. C. B. P.* Leſſer red Lily, with a double Flower.
22. **Lilium** *cruentum polyanthos. Hort. Eyſt.* Fiery Lily with many Flowers.
23. **Lilium** *bulbiferum latifolium majus. C. B. P.* Greater broad-leaved Bulb-bearing Lily.
24. **Lilium** *bulbiferum minus. C. B. P.* Smaller Bulb-bearing Lily.
25. **Lilium** *floribus reflexis, montanum, flore albicante. C. B. P.* The Martagon, with a whitiſh Flower.
26. **Lilium** *floribus reflexis, montanum, flore maculis rubris inordinatis aſperſo.* The Martagon with Flowers ſpotted inordinately with red.
27. **Lilium** *floribus reflexis, montanum, flore carneo. H. R. Par.* The pale-red or fleſh-colour'd Martagon.
28. **Lilium** *floribus reflexis, montanum, longiore ſpica. C. B. P.* The Martagon, with a long Spike of Flowers.
29. **Lilium** *floribus reflexis variis, ſive tertium. C. B. P.* The ſtriped Martagon.

30. LILIUM *floribus reflexis, polyanthos album punctatum. C. B. P.* The white ſpotted Martagon, with many Flowers.

31. LILIUM *Byzantinum ſerotinum. Hort. Eyſt.* The late-flowering Martagon of *Conſtantinople.*

32. LILIUM *floribus reflexis, Americanum maximum, flore rubente, ſerotinum.* The greateſt *American* late-flowering Martagon, with red Flowers.

The common white *Lily* is ſo well known, that it will be needleſs to ſay any thing of it in this Place: The ſecond Sort with double Flowers, is by ſome Perſons preſerved by way of Curioſity; but there is no Beauty in it, for the Flowers ſeldom open, and have no Scent, ſo that it ſcarcely deſerves a Place in a good Garden: The third Sort with pendulous Flowers, is ſometimes called the *White Conſtantinople Lily*, from whence it was formerly brought, but is now become almoſt as plenty as the common white *Lily* in many Gardens; this differs from the common Sort, in having ſlenderer Stems which are of a purpliſh Colour, and the Petals of the Flowers are narrower, and the Flowers are ſomewhat leſs, and always hang down.

Theſe Plants are all very hardy, and require no other Culture, than to be taken up every other Year, (in *July* after the Flowers are decay'd) and pull off the Suckers from them, which if ſuffer'd to remain on, would ſtarve the old Roots, and cauſe them to flower very weak; but they ſhould not be kept long out of the Ground, nor removed after their Leaves appear above Ground, both which will weaken the Roots ſo much, that they will not flower the following Summer. They increaſe greatly from Off-ſets, whereby they are become ſo common as to be little eſteem'd.

The fourth Sort ſeems to be a Variety from the firſt: The Stalks of this are very broad, and have generally double the Number of Flowers upon each Stalk as the common, which are equally as large and fair: But whether it will conſtantly preſerve this Difference, I can't poſitively affirm, tho' for three Years paſt I have obſerv'd them to remain the ſame in two or three different Gardens. This is equally hardy as the common Sort, and is increas'd the ſame way.

The *Strip'd-leav'd Lily* is a great Ornament to Flower-Borders during the Winter Seaſon; their beautiful variegated Leaves always appearing in *September*, and are continued all the Winter, making a fine Appearance in the Depth of Winter, when few other Plants are in Beauty: For which Reaſon this Plant hath been greatly propagated of late Years. This is increas'd as the common Sort, but the Roots ſhould always be planted in a freſh, light Soil, in which they will thrive exceedingly: But if you make the Ground rich with Dung, it will certainly deſtroy them, as will alſo a very wet or ſtrong Soil. The Seaſon for tranſplanting theſe Roots, is the ſame with the common Sort.

The *White Lily ſtrip'd with Purple* has not been many Years brought into *England.* Of this Kind there are two Sorts; one of which is much more beautifully variegated than the other; both of which were obtain'd originally from Seed. Theſe are both propagated in the ſame manner as the common Sort, but ſhould be planted in a dry, ſandy Soil, mix'd with a little Lime-rubbiſh, and expos'd to the Morning Sun: In which Soil and Situation they will flower exceeding well, and their Stripes will be much deeper colour'd than when they are planted in a richer Soil, and their Roots will make a better Increaſe.

The *Orange Lily* is ſo well known, that it is needleſs to ſay any thing of it here. That Sort which is commonly call'd the *Double Orange Lily*, differs from the common only in having two or three more Petals in each Flower, which is not conſtant, but very apt to degenerate to the common Sort, ſo that it is ſcarcely worth preſerving, unleſs for Variety-ſake. Theſe are propagated by Off-ſets from the old Roots, which are commonly ſent forth in great Plenty, and therefore the Roots ſhould never remain more than two Years unremov'd, becauſe the Number of Off-ſets would greatly weaken them, and renner their Flowers ſmall, and fewer in Number. Theſe may be tranſplanted any Time from the Beginning of *Auguſt* to the End of *October*, for they do not ſhoot again ſoon after their Stems are decay'd, as do the *White Lilies*; but, on the contrary, remain till *February* before they appear above Ground. They will grow in almoſt any Soil or Situation, but beſt in a dry, light Soil, and an open Expoſore.

The *bulbous fiery Lily*, produces its Flowers three Weeks before the common Sort, and is much more beautiful. This Sort was formerly more common than at preſent, as were ſeveral other Sorts of *Lilies*: It is equally as hardy as the common Sort, and doth increaſe much faſter; for upon the Flower-ſtems, between the Wings of the Leaves and the Stalk, are produc'd ſmall Bulbs; which when taken off, and planted, do become ſtrong Roots in two Years, ſo that it may be render'd very plentiful in a ſhort Time, were People to plant all their Increaſe. This requires the ſame Soil and Culture as the *Orange Lily*; as doth alſo the *Dwarf Red Lily*, which is nearly allied to this. They will grow under Trees, which renders them proper to plant in Avenues; where, when intermix'd amongſt other hardy Flowers of the ſame Growth, they will make a beautiful Appearance, and are very uſeful to furniſh Baſons and Flower-pots for Halls, Chimnies, *&c.* during the Seaſon of Flowering.

The *Imperial Martagon* is very common in moſt old Gardens in *England.* This is equally as hardy as the common *Lily*, and requires no other Culture: The Flowers are produc'd at the latter End of *May*, and do make a very handſome Figure in the Middle of large Borders in a Flower-Garden, but the Scent is too ſtrong to be borne by many People; for which Reaſon they ſhould never be plac'd in Baſons of Flowers in a Room, nor be planted too near the Houſe.

The *White* and the *White-ſpotted Martagons*, do flower about the Middle of *June*, or ſometimes later: Theſe produce a greater Number of Flowers upon a Stalk than the former, but the Flowers are ſeldom ſo large, and commonly grow more ſparſedly on the Stalks. Theſe have a ſtrong Scent, but not quite ſo diſagreeable as the former. The Roots of theſe Plants ſhould be tranſplanted ſoon after their Stems decay; for if they are taken up late in the Autumn, they ſeldom produce their Flowers ſtrong the ſucceeding Summer. Theſe require a freſh, light Soil, and an open Situation; if they are ſuffer'd to remain three Years undiſturb'd, they will make a good Increaſe, and produce ſtrong Flowers.

The *Double Martagon* requires the ſame Soil and Culture with the two laſt: This produces a large Quantity of fair double Flowers upon each Stem, which renders it very valuable: The Flowers do commonly appear the Beginning of *July*, or ſomewhat later.

The *Spotted Canada Martagon*, is much tenderer than any of the former. The Roots of this Sort ſhould be planted in a warm Border, where they may be protected from ſevere hard Froſts, by covering the Surface of the Ground with Peas-haulm, *&c.* It muſt alſo have a freſh, light, dry Soil, and ſhould be planted at leaſt ſix Inches deep: for when the Roots lie near the Surface, they are often injur'd by Froſts in Winter.

This Plant was originally brought from *Canada* by the *French*, from whom we were firſt ſupply'd with it; but ſince we have receiv'd many Roots of it from *Virginia*, where it alſo grows in great Plenty in the Woods. The Flowers of this Kind are almoſt as large as thoſe of the *Orange Lily*, but are more reflex'd, and of a fine yellow Colour, ſpotted with Black: This flowers in *July*.

The *Red Martagon of Pompony*, is one of the moſt beautiful Sorts of all the *Martagons* which I have yet ſeen, and produces the greateſt Number of Flowers upon a Stem of any of the Kinds, (eſpecially when the Roots are ſtrong, and have remain'd undiſturb'd two or three Years) when they will many Times have upward of fourſcore Flowers upon a Stem: The Flowers are not ſo large, nor ſo deep-colour'd as the *Scarlet Martagon*, but rather of a yellowiſh-red Colour, and ſpotted with black: This flowers commonly the latter End of *May*, or the Beginning of *June.*

The Roots of this Plant are tender, and will not endure to be often tranſplanted, for that will deſtroy them: The beſt Seaſon to remove them, is ſoon after their Stems decay; when they ſhould never be kept long out of the Ground, but planted again as ſoon as poſſible. Theſe require a freſh, light, ſandy Soil, but will by no means thrive in a rich, moiſt Soil, which will cauſe 'em to rot; and they muſt have an open Expoſure, for if they are over-hung by Trees, they will not thrive. This ſhould alſo be planted as deep in the Ground as the *Canada Martagon*, for the ſame Reaſon as was before obſerv'd on that.

The *Scarlet Martagon*, with many Flowers, is in ſome curious Gardens very common, it being a very hardy Plant in reſpect to Cold, which it endures very well, and is eaſily propagated from Off-ſets, as the other Sorts; but muſt have a warm, light, dry Soil, which ſhould not be dung'd, nor overſhadow'd with Trees, either of which will cauſe the Roots to decay. This is a very beautiful Flower, and very proper to adorn the Borders of large Flower-Gardens. It produces its Flowers in *July*, after moſt of the other Sorts, which are of a deep-ſcarlet Colour, growing many upon a Stalk.

The other *Scarlet Martagon* is alſo common in ſome Gardens, but is not ſo much valu'd as the laſt; the Flowers are not ſo deep colour'd, and it ſeldom has more than ſix or eight upon a Stem. This flowers much about the ſame Time as the former, and requires the ſame Soil and Culture.

The *Yellow Martagon of Conſtantinople* is very rare in *England* at preſent, and only to be found in the Gardens of ſome curious Collectors of theſe Beauties: This requires much the ſame Culture as the two laſt mention'd, but muſt not be often remov'd, which will not only weaken the Root, but alſo prevent its flowering. When the Roots of this Kind have been ſtanding three Years upon a good freſh dry Soil, I have obſerv'd above forty Flowers upon a Stem, which have made a very beautiful Appearance. This flowers about the ſame Seaſon as the former.

The *ſtrip'd Orange Lily* is a very beautiful Plant, and was a few Years ſince ſold at a very great Price; but of late it hath been more common, as being eaſily propagated by Off-ſets; ſo that when it is once obtain'd, it may be ſoon increas'd to what Number you pleaſe, provided you plant it in a dry Soil, and a warm Situation. This beautiful Plant was, ſome Years ſince, accidentally produc'd from Seeds of the common *Orange Lily*, which were ſhed upon a Border, where they were ſuffer'd to grow, until this Plant appear'd with its fine variegated Leaves; which the Owner, upon Diſcovery, mark'd, and, at a proper Seaſon, remov'd into a better Situation, where it throve and increas'd ſo well, as in a few Years to be ſpread into divers Parts of the Kingdom. This Plant muſt never be planted in a rich Soil, which will greatly diminiſh its Beauty, and many times cauſe the Roots to decay.

All the Sorts of *Lilies* and *Martagons* may be propagated by ſowing their Seeds; by which Method ſome new Varieties may be obtain'd, provided the Seeds are ſav'd from the beſt Sorts, eſpecially the *Martagons*, which are more inclinable to vary than the other *Lilies*. The manner of ſowing them is as follows:

You muſt be provided with ſome ſquare Boxes about ſix Inches deep, which ſhould have Holes bored in their Bottoms, to let the Wet paſs off; theſe Boxes ſhould be fill'd with freſh light ſandy Earth, and in the Beginning of *Auguſt*, ſoon after the Seeds are ripe, you muſt ſow them thereon pretty thick, covering 'em over with light ſifted Earth about half an Inch; then place the Boxes where they may have the Morning Sun only, obſerving, if the Seaſon ſhould prove dry, to refreſh 'em often with Water as alſo to pull out all Weeds which may be produc'd: In this Situation the Boxes ſhould remain until *October*, when you muſt remove 'em where they may have as much Sun as poſſible, as alſo to be ſcreen'd from the cold North and Eaſt Winds during the Winter Seaſon: But in the Spring of the Year, about the Beginning of *April*, you muſt remove the Boxes into their former Poſition; for now the young Plants will appear above Ground, which are impatient of too much Heat: beſides, the Earth in the Boxes will dry too faſt at this Seaſon, if expos'd to the full Sun at Noon. You muſt alſo obſerve at this Seaſon to keep them intirely clear from Weeds, as alſo to refreſh them gently with Water if the Seaſon ſhould prove dry; in this Place you ſhould let the Boxes remain until the Beginning of *Auguſt*, at which Time you ſhould prepare ſome Beds of the above-mention'd freſh light Earth, which muſt be levell'd very even: Then take the Earth out of the Boxes, together with the ſmall Bulbs, and ſtrew it equally over the Beds, covering it over about half an Inch thick with fine-ſifted Earth: And if the Seaſon ſhould prove very hot and dry, you would do well to ſhade the Beds in the Middle of the Day from the great Heat of the Sun, and refreſh them now and then with Water.

You muſt alſo obſerve to keep them intirely clear from Weeds: And if the following Winter ſhould prove very cold, you muſt cover the Beds with Peas-haulm, or ſome other light Covering, to keep out the Froſt, which would prejudice the Roots, if ſuffer'd to enter deep into the Ground, (eſpecially while they are ſo young): but you muſt never let the Covering remain on in mild Weather, which would alſo be very injurious to them.

In *February*, when the hard Froſts are over, you ſhould gently clear off the Earth upon the Surface of the Beds, (which, during the Winter Seaſon, will often have contracted a Moſſineſs) and ſift a little freſh Earth equally over the Beds, which will greatly encourage the Roots: But in doing this, you muſt be very careful not to ſtir the Ground ſo deep as to injure the Roots: Nor ſhould you defer doing it too late, leſt the Shoots ſhould be coming up, which, by this Operation, might be broken, and greatly hurt. And as the Seaſon advances, ſo you muſt be careful to clear them from Weeds, and in dry Weather to water them; and in very hot Days, if you ſhade 'em from the Sun, it will be of great Service to them: but this need not be done 'till the Latter end of *April*, or the Beginning of *May*, when the Seaſon is ſometimes very hot and dry.

When their Leaves are quite decay'd, you ſhould ſtir the Surface of the Beds again, (but do not go too deep) which will prevent the Weeds from growing very faſt, and be of Service to the Roots; and in *September* you muſt ſift ſome more freſh Earth over the Beds about half an Inch thick: and in Winter and Spring you muſt manage them as was directed for the preceding Year.

In *September* following theſe Roots will require to be tranſplanted to a greater Diſtance, when you muſt prepare ſome Beds of the ſame freſh light Earth, as was before directed, making them level; then take up the Roots, and tranſplant them into the Beds, placing them about eight Inches aſunder, obſerving to put the Roots with their Buds uppermoſt, and about four Inches below the Surface.

This Work ſhould be done when the Weather is moiſt; for if the Roots are tranſplanted in a very dry Seaſon, and there doth not happen Rain ſoon after, they will take a Mouldineſs, which many times rots them.

You muſt alſo obſerve (as was before directed) to keep the Beds intirely clear from Weeds: And in Winter, if the Froſt ſhould be very ſevere, you muſt cover them with Peas-haulm, to prevent the Roots from being injured thereby: And in the Spring you ſhould take off the Earth from the Surface of the Beds, as before, laying ſome freſh thereon, and ſo continue the Summer and Winter's Work, as before.

The ſecond Year after being planted in theſe Beds the ſtrongeſt Roots will begin to flower; at which Time, if you obſerve any peculiar Varieties, you ſhould put down a Stick by each of thoſe Roots, to mark them; which may be taken up when their Leaves are decay'd, and remov'd into the Borders of the *FlowerGarden*, or tranſplanted into other Beds at greater Diſtance, to encourage them to flower ſtrong. But you can't be a Judge which of thoſe will be good by their firſt Flowers, therefore you ſhould never reject any of them until they have flower'd two or three Years; for, many Times, ſome of theſe Flowers will make but a mean Appearance the firſt Year, and afterwards become fair handſome Flowers, when they have obtain'd Strength; ſo that you ſhould ſuffer all ſuch, as you are not aſſured of their Worth, to remain undiſturb'd two or three Years, that you may be aſcertain'd which of them are worthy preſerving; which ſhould be remov'd into the *Flower-Garden* at a proper Seaſon: but the ordinary ones may be rejected, or planted in ſhady Outer Walks, where, tho' they are mean Flowers, yet they will appear well enough in ſuch Places.

The twenty-firſt, twenty-ſecond and twenty third Sorts of *Lily* are not very common in the *Engliſh* Gardens at preſent, but ſome Years ſince they were in greater Plenty; for as the Taſte for Gardening has greatly changed in *England* of late Years, ſo few People have been curious enough to preſerve many of the good old Flowers; but have been fond of introducing new Kinds, which are not ſo beautiful as many of the old ones, which they turned out to make room for the new ones. Theſe Sorts are ſometimes found in ſome old Country Gardens, which have not been torn to pieces, from whence ſome few Perſons have retrieved them. In *Holland* they are more curious in preſerving all the Kinds of bulbous and tuberoſe-rooted Flowers, than in moſt other Parts of *Europe*; ſo that they have a very great Variety of theſe old Flowers in their Gardens.

The twenty-fourth Sort is pretty common in ſeveral Gardens near *London*: this may be increaſed very faſt, by planting of the ſmall Bulbs, which come out upon the Stalks between the Leaves, which will ſoon become ſtrong Roots for Flowering; but theſe Bulbs ſhould not be taken off, until the Stalks are beginning to decay.

The twenty-fifth, twenty-ſixth, twenty-ſeventh, twenty-eighth, twenty-ninth, thirtieth and thirty-firſt Sorts of Martagon, deſerve a Place in every curious Flower-Garden, for the Variety of their Flowers. Theſe are all preſerved by the curious Floriſts in *Holland*, but are not very common in the *Engliſh* Gardens.

The thirty-ſecond Sort was ſent from *Penſylvania* (where it grows in the Woods) to Mr. *Peter Collinſon*, who has a great Variety of theſe curious Flowers in his Garden at *Peckham*.

LILIUM CONVALLIUM; Lily of the Valley, *or* May Lily.

The *Characters* are;

The Flower conſiſts of one Leaf, is ſhap'd like a Bell, and divided at the Top into ſix Segments: The Ovary becomes a ſoft globular Fruit, containing ſeveral round Seeds.

The *Species* are;

1. Lilium Convallium *album*. *C. B. P.* Common Lily of the Valley, with white Flowers.
2. Lilium Convallium *flore rubente*. *C. B. P.* Lily of the Valley, with reddiſh Flowers.

3. LILIUM CONVALLIUM *latifolium, flore pleno variegato. Tourn.* Broad-leav'd Lily of the Valley, with a double variegated Flower.

There are ſome other Varieties of this Plant, which are preſerv'd in ſome curious Botanick Gardens abroad, but theſe are all the Sorts I have obſerv'd in the *Engliſh* Gardens. The firſt Sort is very common in ſhady Woods in divers Parts of *England*. The ſecond is a Variety of the firſt, differing only in the Colour of the Flower; which Difference it conſtantly maintains when cultivated in Gardens.

They delight in a moiſt ſhady Situation, where they will thrive exceedingly, and produce a large Quantity of Flowers. The beſt Time for tranſplanting theſe Roots is early in the Spring, juſt before they begin to ſhoot.

The Double Sort was brought from *Holland* ſome Years ſince; but whether it was obtain'd from Seeds originally, or found by Accident, I can't ſay. This may be propagated by parting the Roots in the Spring, in the ſame manner as the former.

LILIUM PERSICUM. *Vide* Fritillaria.

LILIUM SUPERBUM. *Vide* Methonica.

LIME-TREE. *Vide* TILIA.

LIMON, [ſo call'd of Λειμὼν a *Meadow*, becauſe the Leaves of this Tree are of a green Colour, as is likewiſe the Fruit before it comes to Maturity] The Lemon-Tree.

The *Characters* are;

It hath large ſtiff Leaves like the Citron, *without any Appendage at the Bottom; the Flower conſiſts of many Leaves, which expand in Form of a* Roſe; *the Fruit is almoſt of an oval Figure, and divided into ſeveral Cells, in which are lodg'd hard Seeds ſurrounded by a thick fleſhy Subſtance, which, for the moſt part, is full of an acid Juice.*

The *Species* are;

1. LIMON *vulgaris. Ferr. Heſp.* The Common Lemon.
2. LIMON *dulcis. Ferr. Heſp.* The Sweet Lemon.
3. LIMON *acris. Ferr. Heſp.* The leſſer ſour Lemon.
4. LIMON *dulci medulla, vulgaris. Ferr. Heſp.* The Common ſweet Lemon.
5. LIMON *pyri effigie. Ferr. Heſp.* The Pear-ſhap'd Lemon.
6. LIMON *Imperialis. Ferr. Heſp.* The Imperial Lemon.
7. LIMON *Adami Pomum commune. Ferr. Heſp.* Lemon, *commonly call'd* Adam's Apple.
8. LIMON *ſpineolas. Ferr. Heſp.* The wild Lemon, *vulgo.*
9. LIMON *ſtriatus vulgatior. Ferr. Heſp.* The furrow'd Lemon.
10. LIMON *citratus altero fœtus. Tourn.* The Childing Lemon, *vulgo.*
11. LIMON, *qui lima acris dicitur. Ferr. Heſp.* The ſour Lime.
12. LIMON, *qui lima dulcis dicitur. Ferr. Heſp.* The ſweet Lime.
13. LIMON *vulgaris, foliis ex luteo eleganter ſtriatis.* The Gold-ſtrip'd Lemon.
14. LIMON *vulgaris, foliis ex albo variegatis.* The ſilver-ſtrip'd Lemon.

There are ſome other Varieties of theſe Trees in the curious Gardens abroad, from whence we may expect to be ſupply'd with them all, ſince there are every Year large Quantities of theſe Trees brought over from *Italy*, where the Gardeners are as fond of any new Kinds to ſupply their Cuſtomers with, as our Country-men are of new Sorts of Fruit. But ſince theſe Varieties are annually increas'd from Seeds, like other Fruits, ſo it would be needleſs to attempt an Account of them all, becauſe in a very ſhort Time many new Varieties may be produc'd.

The Fruit of the four firſt Sorts are generally brought over from *Liſbon* every Year in great Plenty, and are ſold promiſcuouſly in *London* in the Winter and Spring, as are great Numbers of the Trees, which are annually brought over from *Italy.*

The fifth, ſixth, and ſeventh Sorts are preſerv'd, for their Variety, in many curious Gardens; but the fifth is very uncommon in *England* at preſent.

The ſixth is a very large beautiful Sort, and of an agreeable Flavour: This has produc'd very good Fruit in divers Gardens in *England*, which has been as well-taſted as any of thoſe which are brought over from *Italy.*

The ſeventh Sort is ſomewhat tenderer than the other, and requires a warmer Situation in Winter; otherwiſe the Fruit is very ſubject to drop off at that Seaſon.

The eighth Sort is commonly call'd the *Wild Lemon*, (though improperly) becauſe it has many Thorns upon the Branches; but this will produce very fair Fruit in this Kingdom. The Flowers of this Kind are generally of a reddiſh or purpliſh Colour on the Outſide before they open, but afterwards fade, and change to a paler. The Leaves of this are alſo of a very deep Green, and gently ſerrated upon their Edges.

The *furrow'd Lemon* is in divers Gardens in *England*, where the Fruit very often ripens well, and is chiefly kept for Variety, as differing from the common Sort, in having deep Furrows in the Fruit; but it is not ſo good for Uſe, nor does the Fruit produce ſo much Juice as the Common Sort.

The *Childing Lemon* is alſo preſerv'd as a Curioſity, the old Fruit commonly producing a young one from its Centre.

The two Sorts of *Limes* are likewiſe in many Gardens in this Kingdom; but theſe require the ſame Degree of Warmth as the *Shaddock Orange*, in order to produce Fruit; for if they are placed among *Orange-Trees*, the Fruit will fall away in Winter, and come to nothing.

The two variegated Sorts are preſerv'd for their ſtrip'd Leaves (which are greatly eſteem'd by ſome Perſons who are curious in collecting variegated Plants): But theſe are tenderer than the plain Sorts, and, if not duly attended in Winter, will be very apt to caſt their Leaves, and appear very unſightly.

There is alſo another Sort, which produces double Flowers; but this ſeems not to be very conſtant; for I have obſerv'd upon the ſame Tree, ſome Flowers ſingle, and others double, at the ſame Time.

All theſe Sorts are propagated by budding or inarching them either on Stocks of *Lemons* or *Citrons* produc'd from Seeds; but they will not ſo readily unite on *Orange* Stocks; for which Reaſon the *Citrons* are preferable to either *Oranges* or *Lemons* for Stocks, as they do readily join with either Sort; and being of larger Growth, do cauſe the Buds of the other Sorts to ſhoot much ſtronger than if they were on Stocks of their own Kind. The Method for raiſing theſe Stocks, and the Manner of Budding them, being already exhibited under the Article of *Aurantium*, it wou'd be ſuperfluous to repeat it here.

The Culture of the *Lemon* being the ſame with that of the *Orange-Tree*, it wou'd be alſo needleſs to repeat it here; therefore I ſhall only obſerve, that the *common Lemons* are ſomewhat hardier than the *Oranges*, and will bring their Fruit to Maturity with us better than They will do, and require to have a greater Share of freſh Air in Winter; for which Reaſon they ſhould always be placed nearer to the Doors or Windows of the Green-houſe: And as they generally produce ſtronger Shoots, ſo they require more Water to be given them than the *Orange*; but as to the tender Sorts, they muſt be treated with a little more Care, otherwiſe their Fruit will fall off in Winter, and come to nothing. Theſe Things being fully exhibited before, I refer the Reader (as I hinted) to the Article *Aurantium*, where their Culture is fully ſet forth.

LIMONIUM, takes its Name of Λειμῶν, a *Marſh*, as growing in Marſhes] Sea-Lavender.

The *Characters* are;

It hath a fibroſe Root; the Stalks are naked, and branched; the Cup of the Flower is long and tubuloſe, but expanded at the Top; the Flower in ſome Species conſiſts of one Leaf, but in others of ſeveral, and is ſhap'd like a Clove-Gilliflower; *the Pointal, which ariſes out of the Flower-cup, becomes an oblong Fruit, wrapt up in the Flower-cup, as in an Huſk.*

The *Species* are;

1. LIMONIUM *maritimum majus. C. B. P.* Common Great Sea-Lavender.
2. LIMONIUM *maritimum majus alterum ſerotinum Narbonenſe. H. R. Par.* Another large late flowering Sea-Lavender of *Narbonne.*
3. LIMONIUM *maritimum minus, oleæ folio. C. B. P.* Small Sea-Lavender, with an Olive-Leaf.
4. LIMONIUM *Anglicum minus, caulibus ramoſioribus, floribus in ſpicis rarius ſitis. Raii Hiſt.* Leſſer *Engliſh* Sea-Lavender, with branch'd Stalks, and Flowers ſeldom growing in a Spike.

5. **Limonium** *Orientale, plantaginis folio, floribus umbellatis. T. Cor.* Oriental Sea-Lavender, with Plantain Leaves and Flowers growing in an Umbel.

6. **Limonium** *peregrinum, foliis aſplenii. C. B. P.* Foreign Sea-Lavender, with Spleenwort Leaves.

7. **Limonium** *Siculum lignoſum, gallas ferens & non ferens. Bocc. Rar.* Woody *Sicilian* Sea-Lavender.

There are ſeveral other Species of this Plant, which are found upon the Sea-coaſts of *Italy*, *Spain*, and the ſouthern Parts of *France*, but theſe here mention'd are all the Sorts I have obſerv'd in the *Engliſh* Gardens. The firſt and fourth Sorts are found upon the Sea-Coaſts in divers Parts of *England*, eſpecially the firſt, which is the moſt common; the other being only found in ſome particular Places. The ſecond and third Sorts are pretty common in the ſouthern Parts of *France*. The fifth Sort was found by Monſ. *Tournefort* in the *Levant*. The ſixth, which is the moſt beautiful of all the Sorts, was found by Mr. *Ray* in great Plenty in divers Parts of *Sicily*; and *Cluſius* obſerv'd it at *Malaga*, and about *Cadiz*. The ſeventh Sort, which grows to the Stature of a Shrub, was found in *Sicily* by *Pere Boccone*, and by him figur'd and deſcrib'd in his Book of *Rare Sicilian Plants*.

The five firſt mention'd Sorts are pretty hardy, and will endure the Cold of our ordinary Winters very well, provided they have a ſandy Soil, and a warm Situation: Theſe may be propagated by parting their Roots towards the latter End of *March*. When they are planted, which ſhould be in a light ſandy Soil, you muſt water and ſhade them until they have taken Root; after which, they will require no other Culture than to keep them clear from Weeds. In *July* theſe Plants will produce beautiful Spikes or Tufts of blue or Purple-colour'd Flowers, which will continue in Perfection a long Time; and if the Seaſon proves favourable in Autumn they will ripen their Seeds.

The ſixth Sort is ſomewhat tenderer than the others, and muſt be preſerv'd in Pots fill'd with freſh light Earth, and plac'd in the Green-houſe in hard Weather, otherwiſe the Cold of our Winters often deſtroys them: This Plant muſt be propagated by Seeds, for it ſeldom lives longer than two Years; for which Reaſon, the beſt Method is, to be furniſh'd with good Seeds from abroad, (for it ſeldom perfects its Seed in *England*), which, if ſown upon a warm Border of light freſh Earth, will come up very well; and in the Summer, when the Plants have acquir'd ſufficient Strength for Tranſplantation, they muſt be taken up and planted in Pots, placing them in the Shade until they have taken Root; after which, they may be expos'd to the open Air until *October*, when they muſt be remov'd into the Green-houſe, obſerving to place them where they may have as much free Air as poſſible in mild Weather: And during the Winter-ſeaſon they muſt be frequently water'd; but you muſt never give them too much at once, which is apt to rot their Roots, eſpecially in that Seaſon. You muſt alſo obſerve to pick off all decay'd Leaves, which, if ſuffer'd to remain on the Plants, very often infect them; and it being pretty nice in its Culture, it will often fail, upon a ſmall Neglect of this Kind. This Plant produces its Flowers in *July* and *Auguſt*, and, many Times, continues in Beauty the greateſt Part of *September*.

The ſeventh Sort riſes to be four or five Feet high, and hath ſlender woody Branches; from which, in *July* and *Auguſt*, are produc'd Spikes of ſmall blue Flowers, which make a very handſome Appearance, (eſpecially in a warm Seaſon, when their Flowers open kindly) and continue in Beauty a long Time.

This Plant is propagated by planting ſome of the tender Cuttings in any of the Summer Months, in Pots fill'd with light ſandy Earth, and placed in a moderate Hot-bed to facilitate their taking Root, and after they are rooted, they may be expos'd to the open Air until *October*; when they muſt be remov'd into a Green-houſe, placing them in a Situation where they may have as much free Air as poſſible in mild Weather: During the Winter-ſeaſon, they ſhould have frequent, but gentle Refreſhings with Water: You muſt alſo obſerve to keep them clear from decay'd Leaves and Branches, which will infect the whole Plants upon which they are ſuffer'd to remain; and in the Summer-ſeaſon they ſhould be expos'd in ſome well-ſhelter'd Place amongſt other exotick Plants.

LINARIA; [ſo call'd of *Linum*, Lat. *Flax*, becauſe its Leaves reſemble *Flax*] Toad-Flax.

The *Characters* are;

The Leaves are oblong, and produced alternately on the Branches; the Cup of the Flower conſiſts of one Leaf, which is divided into five long acute Segments; the Flower, which conſiſts of one Leaf, is of an anomalous, perſonated Figure, ending in a Tail behind, and in the Fore-part divided into two Lips, of which the Upper is cut into two or more Parts, and the Under into three; the Ovary, (which riſes from the Center of the Flower-cup) becomes a roundiſh Fruit or Huſk, divided into two Cells or Apartments, by an intermediate Partition, and full of Seeds, which are ſometimes flat and border'd, ſometimes corner'd and roundiſh, adhering to the Placenta.

The *Species* are;

1. **Linaria** *vulgaris lutea, flore majore. C. B. P.* Common Yellow Toad-flax, with a large Flower.

2. **Linaria** *purpurea major odorata. C. B. P.* Great Purple ſweet-ſmelling Toad-flax.

3. **Linaria** *latifolia Dalmatica, magno flore. C. B. P.* Broad-leav'd *Dalmatian* Toad-flax, with a large Flower.

4. **Linaria** *latiſſimo folio, Luſitanica. Tourn.* Broad-leav'd *Portugal* Toad-flax.

5. **Linaria** *Hiſpanica procumbens, foliis glaucis, flore luteo ſtriato, labiis nigro-purpureis. Spaniſh* trailing Toad-flax, with Sea-green Leaves, and yellow ſtriped Flowers with purple Lips.

6. **Linaria** *Sicula multicaulis, folio molluginis. Bocc. Rar. Sicilian* Toad-flax, with many Stalks, and a Leaf of the White Lady's Bed-ſtraw.

7. **Linaria** *tryphilla minor lutea. C. B. P.* Small three-leav'd yellow Toad-flax.

8. **Linaria** *tryphylla minor lutea, floris vexillo & calcari purpureo. Boerh. Ind.* Small three-leav'd yellow Toad-flax, with the Standard and Heel of a purple Colour.

9. **Linaria** *ſegetum, nummulariæ folio villoſo. Inſt. R. H.* Corn Toad-flax, with a hairy Money-wort Leaf, commonly called Fluellin or Female-ſpeedwel.

10. **Linaria** *ſegetum, nummulariæ folio aurito & villoſo, flore luteo. Inſt. R. H.* Corn Toad-flax, with a hairy-eared Money-wort Leaf, and a yellow Flower.

11. **Linaria** *pumila vulgatior arvenſis. Inſt. R. H.* Common low annual Toad-flax.

12. **Linaria** *hederaceo folio glabro, ſeu Cymbalaria vulgaris. Inſt. R. H.* Toad-flax with a ſmooth Ivy-leaf, commonly known by the Name of *Cymbalaria*.

13. **Linaria** *quadrifolia lutea. C. B. P.* Four-leaved yellow Toad-flax.

14. **Linaria** *annua anguſtifolia, floſculis albis longius caudatis. Triumphet.* Narrow-leav'd annual Toad-flax, with ſmall white Flowers, having long Tails or Spurs.

15. **Linaria** *quadrifolia ſupina. C. B. P.* Trailing four-leaved Toad-flax.

16. **Linaria** *capillaceo folio, odora. C. B. P.* Sweet-ſmelling Toad-flax, with a very narrow Leaf.

17. **Linaria** *Orientalis, flore luteo maximo. Tourn. Cor.* Eaſtern Toad-flax, with a very large yellow Flower.

18. **Linaria** *latifolia triphylla, flore purpureo magno, rictu aureo. Inſt. R. H.* Broad three-leav'd Toad-flax, with a large purple Flower having a golden Standard.

19. **Linaria** *annua anguſtifolia, flore majore luteo. Mor. Hiſt.* Narrow-leav'd annual Toad-flax, with a larger yellow Flower.

The firſt of theſe Plants grows in great Plenty upon the Sides of dry Banks in moſt Parts of *England*, and is ſeldom cultivated in Gardens, for it is a very troubleſome Plant to keep within Bounds, the Roots being very apt to ſpread underground, and riſe at a great Diſtance from the Mother-Plant, whereby it greatly injures whatever Plants ſtand near it. This is the Species mention'd in the Catalogue of Simples at the End of the College Diſpenſatory to be us'd in Medicine.

The ſecond is a perennial Plant, which is often cultivated in Gardens: This produces fine Spikes of purple Flowers in *June* and *July*, and it being a very hardy Plant, growing in almoſt any Soil or Situation, ſhould be admitted into every good Garden, where it may be planted in ſhady Situations, or upon the Middle of large Borders in the Pleaſure-Garden; in which Place it will make an handſome Appearance, and continues a long Time in Flower.

This Plant is propagated by ſowing the Seeds in the Spring, which will come up ſoon after; and the Plants muſt be tranſplanted out into Beds at the Diſtance of ſix or eight Inches; in which Beds they may remain until the *Michaelmas* following, (obſerving to keep them clear from Weeds): At which Time they ſhould be tranſplanted into the Places where they are to remain for good, and will require no other Culture than only to keep them clear from Weeds; and when the Flower-ſtems advance in the Spring, they ſhould be ſupported by Stakes, otherwiſe they are ſubject to be broken by ſtrong Winds: They may alſo be propagated by parting their Roots in Autumn; but as the Seed ripens very well, ſo it is the better Way to raiſe them from that.

The third and fourth Sorts are tenderer than the laſt, and ſhould be planted in a dry Soil and a warm Situation, otherwiſe they are often deſtroy'd in Winter. Theſe are propagated by Seeds in the ſame Manner as the former, as alſo by parting their Roots; but it is adviſeable always to keep ſome of theſe Plants in Pots, that they may be remov'd into Shelter in the Winter, otherwiſe in hard Froſts they will be kill'd.

The fourth is the moſt beautiful Sort of them all; this produces very large Spikes of purple Flowers, which make a fine Appearance; but it ſeldom produces ripe Seeds in this Country, ſo that the Seeds muſt be obtain'd from Abroad, and the Plants propagated from Off-ſets or Cuttings; which, if planted in the Spring, will take Root very well, whereby it may be maintain'd.

The fifth Sort was brought over from *Gibraltar* by Sir *Charles Wager*, *Anno* 1727, and hath ſince been communicated to ſeveral curious Perſons: This Plant is eaſily propagated by parting the Roots, or planting Cuttings in any of the Summer Months, which if water'd and ſhaded will ſoon take Root, and may afterwards be planted in Pots fill'd with freſh, light, undung'd Earth, in which they will ſucceed much better than in a richer Soil; for if they are planted in a fine rich Earth, it cauſes them to grow very faſt for a ſhort Time, but they ſeldom fail to rot ſoon after. Theſe muſt be remov'd into ſhelter in Winter, where they muſt have as much free Air as poſſible in mild Weather, and be only protected from ſevere Cold; ſo that if the Pots are placed under an Hot-bed Frame, it will be better than to place them in a Green-houſe; and I believe if ſome of the Plants were planted in a dry, rubbiſhy Soil under a warm Wall, they would endure abroad very well in our ordinary Winters.

The ſixth, ſeventh, and eighth Sorts are annual Plants, which ſhould be ſown early in the Spring upon a Bed of light, freſh Earth; and when the Plants are come up about two Inches high, they ſhould be tranſplanted into the Borders of the Flower-Garden, where they are to remain: Theſe produce their Flowers in *June* and *July*, and their Seeds are ripe in *September*. The Seeds of theſe Plants may alſo be ſown in Autumn, ſoon after they are ripe, under a warm Wall or Hedge, where they will endure the Cold of our ordinary Winters very well; and in the Spring they may be tranſplanted out into the Borders, where they are deſign'd to flower: And theſe autumnal Plants will grow much larger, and come to flower much ſooner than thoſe rais'd in the Spring, and from theſe you will always have good Seeds.

The ninth Sort is directed by the College of Phyſicians, to be uſed in Medicine; this ſtands in their Catalogue of *Simples* under the Title of *Elatine*. This and the tenth Sort grow wild amongſt the Corn, in divers Parts of *England*. They are both annual Plants, which ſcatter their Seeds, where-ever they are permitted to grow, and the young Plants generally come up in Autumn; ſo that they are more frequently to be met with amongſt *Wheat*, *Rye*, and other Crops which are ſown in Autumn, than in ſuch Lands as are ploughed in the Spring. The Flowers of theſe Plants are very ſmall, and come out at the Joints cloſe to the Footſtalks of the Leaves, and the whole Plant trails on the Ground; they uſually flower in *June*, and their Seeds are ripe in *Auguſt*.

The eleventh Sort is a low annual Plant, which is very common on arable Land in moſt Parts of *England*; ſo is ſeldom admitted into Gardens.

The twelfth Sort was originally brought from Abroad, but is now become ſo common in many Parts of *England*, as to be thought a Native by ſome Perſons. This has been eſteemed a Plant very efficacious in ſome Diſtempers, but is not uſed by any of the *Engliſh* Phyſicians at preſent. It grows not only on the Ground, but on Walls, Pales, or whatever Place the Seeds fall; ſo it becomes a very troubleſome Weed, where-ever it is ſuffered to ſeed.

The other Seeds are not Inhabitants of this Country; but are by the Curious preſerved in their Gardens, for the Variety of their Flowers. They are all of them Plants of ſhort Duration, ſeldom continuing after they have perfected their Seeds; ſo that where the Seeds are not permitted to ſcatter, they ſhould be ſown every Year, in order to preſerve the Kinds. The Seeds ſhould be ſown in the Places where they are deſigned to remain; for the Plants do not thrive ſo well, when they are tranſplanted. Some of theſe Seeds may be ſown in the Autumn, on a dry Soil, where the Plants will come up, and abide the Winter; and theſe will flower much ſooner the following Year, than thoſe which are ſown in the Spring; ſo that good Seeds may be certainly obtained from thoſe, whereas the Seeds of ſome Sorts do not ripen well in bad Seaſons on ſuch Plants which come up from the Spring-ſowing. But by ſowing at the two Seaſons, there will be a longer Continuance of the Plants in Flower.

As theſe Plants require no farther Care, when they come up, but to thin them where they grow too cloſe, and to keep them clear from Weeds; ſo they may be allowed Room in the Borders of large Gardens, where they will add to the Variety; for they are Plants which do not ſpread far, ſo may be kept in proper Compaſs, and the different Colours of their Flowers will make a pretty Appearance amongſt other hardy Plants.

LINGUA CERVINA; Hart's-Tongue.

Theſe Plants do commonly grow out from the Joints of old Walls and Buildings, where they are moiſt and ſhady, but are ſeldom cultivated in Gardens: There is a very great Variety of theſe Plants both in the *Eaſt* and *Weſt-Indies*, but there are very few of them in *Europe*: They may be propagated by parting their Roots, and ſhould have a moiſt Soil, and ſhady Situation.

LINUM; Flax.

The *Characters* are;

The Leaves, for the moſt part, grow alternately on the Branches; the Cup of the Flower conſiſts of one Leaf, is tubulous, and divided into five Parts at the Top; the Flower conſiſts of five Leaves, which expand in Form of a Clove-Gilliflower; the Ovary, which riſes from the Center of the Flower-cup, becomes an almoſt globular Fruit, which is generally pointed, and compos'd of many Cells, in which are lodg'd many plain, ſmooth Seeds, which are blunt at one End, and generally ſharp at the other.

The *Species* are;

1. LINUM *ſativum. C. B. P.* Manured Flax.
2. LINUM *ſativum latifolium Africanum, fructu majore. Tourn.* Broad-leav'd *African* manured Flax, with a large Fruit.
3. LINUM *maritimum luteum. C. B. P.* Yellow Maritime Flax.
4. LINUM *ſativum humilius, flore majore. Bobart.* Dwarf manured Flax, with a larger Flower.
5. LINUM *perenne majus cæruleum, capitulo majore. Mor. Hiſt.* Greater perennial blue Flax, with a large Head.
6. LINUM *perenne majus cæruleum, capitulo minore. Mor. Hiſt.* Greater perennial blue Flax, with a ſmaller Head.

There are ſeveral Sorts of this Plant which are preſerv'd in ſome curious Gardens of Plants for Variety ſake; but as they are of little Uſe or Beauty, ſo it would be needleſs to mention them in this Place.

The firſt Sort is that which is cultivated for Uſe in divers Parts of *Europe*, and is reckon'd an excellent Commodity; the right Tilling and Ordering of which is eſteem'd a good Piece of Huſbandry.

This ſhould be cultivated upon a rich Soil, that has not been plough'd for ſeveral Years, upon which Flax always makes the beſt Improvement; but as it draws greatly from the Soil, ſo it ſhould not be ſown two Years together upon the ſame Ground.

The Land muſt be well plough'd, laid flat and even, upon which the Seeds ſhould be ſown about the Middle of *March*, when the Weather is mild and warm: During the Spring you muſt carefully weed it; which if neglected, (eſpecially in a moiſt Seaſon) the Weeds will overgrow and deſtroy the Crop. There are ſome People who recommend the feeding of Sheep with *Flax*, when 'tis a good Height, and ſay, they will eat away the Weeds and Graſs, and do the *Flax* good; and if they ſhould lie in it, and beat it down, or flatten it, it will riſe again the next Rain: But this muſt not be practis'd but in a moiſt Seaſon, and upon a rich Soil, for if the Ground be poor, or the Spring dry, it will not riſe again to any conſiderable Height.

The beſt Seed is that which comes from the Eaſt Country, and is known by the Name of *Riga Flax*; for if the *Engliſh* Seed be ſown three or four Times, it is very apt to degenerate: If the Seed be good, two Buſhels will be enough to ſow an Acre; but if it be but middling, there ſhould be a greater Allowance: Toward the latter End of *July* the *Flax* will begin to ripen; when you muſt be careful that it grow not over-ripe, therefore you muſt pull it up as ſoon as the Heads begin to change brown and hang downwards, otherwiſe the Seeds will ſoon ſcatter and be loſt; ſo that the Pluckers muſt be nimble, and tie it up in Handfuls, ſetting them upright till they be perfectly dry, and then houſe them: If the *Flax* be pull'd when it firſt begins to flower, it will be whiter and ſtronger than if it ſtand till the Seed is ripe, but then the Seed will be loſt.

The Method of Watering, Piling, Braking, *&c.* being a particular Buſineſs, and foreign to my Deſign, I ſhall not pretend to give any Directions about it in this Place.

All the other Sorts of *Flax* may be cultivated (by ſuch who have a Curioſity) by ſowing their Seeds upon a Bed of freſh, rich, light Earth, in *March*, or the Beginning of *April*; and when the Plants come up, they muſt be carefully weeded, which is all the Culture they require, and they will produce their Flowers, and perfect their Seeds very well.

LINUM UMBILICATUM. *Vide* Omphalodes.

LIPPIA.

This Plant was ſo named by the late Dr. *William Houſtoun*, who diſcovered it at *La Vera Cruz*, in Honour to Dr. *Auguſtus Lippi*, a famous Botaniſt, who travelled to *Egypt*, and diſcovered many new Plants.

The *Characters* are;

It hath an anomalous Flower, conſiſting of one Leaf, which is divided into four Parts, and reſts on the Embryo, which afterwards becomes the Fruit, having two Seeds, which are incloſed in a ſmall Covering.

We know but one *Species* of this Plant at preſent, *viz.*

Lippia *arboreſcens, foliis conjugatis oblongis, capitulis ſquamoſis & rotundis. Houſt.* Tree Lippia, with oblong Leaves growing by Pairs, and having round ſcaly Heads.

This Plant, in the Country of its Native Growth, commonly riſes to the Height of eighteen or twenty Feet, and hath a rough Bark: The Branches come out by Pairs oppoſite, as alſo the Leaves, which are oblong, pointed, and a little ſawed on their Edges. From the Wings of the Leaves come out the Footſtalks, which ſuſtain many round ſcaly Heads, about the Size of a large *Grey Pea*, in which are many ſmall yellow Flowers appearing between the Scales, which are ſucceeded by the Seed-veſſels.

The Seeds of this Plant were ſent to ſeveral curious Gardens in *Europe*, where ſome of the Plants have been raiſed; but as the Country where it came from, is very warm, ſo the Plants will not thrive in this Country, unleſs they are preſerved in a warm Stove. Theſe may be treated in the ſame Manner as the other ſhrubby Plants, which are Natives of warm Countries; which is, to keep them always in the Stove, plunged in the Bark-bed, obſerving to give them a large Share of Air in warm Weather, and frequently refreſh them with Water; but in Winter they muſt be watered more ſparingly, and be kept in a moderate Degree of Warmth; otherwiſe they will not live thro' the Winter, eſpecially while they are young; but when they have acquired Strength, they may endure a leſs ſhare of Warmth.

As the Plants advance in their Growth, ſo they ſhould be ſhifted into larger Pots; but this ſhould not be too often repeated, for if they are removed into new Pots every Spring, it will be as often as they require; ſo that when theſe, and many other exotick Plants, are too often removed, they do not thrive ſo well as when they are permitted to fill the Pots with their Roots. The beſt Time to ſhift theſe Plants is in *April*, at which Time the Tan of the Hot-bed ſhould be ſtirred, and freſh Tan mixed with it, to increaſe the Heat. The Earth in which theſe Plants are planted, ſhould be freſh and light, but not too rich.

LIQUID AMBER. *Vide* Styrax.

LITHOSPERMUM; [of λίθος, a *Stone*, and σπέρμα, *Seed*, q. d. *Stone-ſeed*, becauſe the Seed of this Plant is hard, and is good againſt the Stone of the Reins and Bladder] Gromwell, Gromill, or Graymill.

The *Characters* are;

The Cup of the Flower conſiſts of one Leaf, which is cut almoſt to the Baſe into five long narrow Segments; the Flower, which is, for the moſt part, ſmall, conſiſts of one Leaf, is Funnel-ſhap'd, and ſpread open at the Top; the Pointal is encompaſs'd by four Embryo's, which become ſo many roundiſh hard poliſh'd Seeds.

The *Species* are;

1. Lithospermum *majus erectum. C. B. P.* Greater Upright Gromill.
2. Lithospermum *perenne procumbens, flore purpureo-cæruleo majore. Mor. Hiſt.* Trailing perennial Gromill, with a purple-blue Flower.

There are ſeveral other Sorts of this Plant, which are mention'd in Botanick Authors, but as they are rarely cultivated in Gardens, I ſhall omit taking Notice of them in this Place. The firſt Sort here mention'd, is that which is order'd for medicinal Uſes: This grows in ſhady Lanes and uncultivated Places in divers Parts of *England*, and is ſeldom cultivated in Gardens. The ſecond Sort is found wild in ſome Parts of *Wales*, but is leſs common than the former. Theſe may be cultivated by ſowing their Seeds ſoon after they are ripe, in a Bed of freſh Earth, allowing them at leaſt a Foot Diſtance from each other, obſerving to keep them clear from Weeds, and they will thrive in almoſt any Soil or Situation.

LOAM is a common ſuperficial Earth, that is a Mixture of Sand and Clay, commonly of a yellowiſh Colour, tho' there is ſome *Loam* that is blackiſh: Some call *Loam* the moſt common ſuperficial Earth met with in *England*, without any Regard to the Proportion it bears to Sand or Clay.

It is found, by Experience, that Plants of all Sorts will grow in it; and where-ever it is found, it appears to be a more beneficial Soil to Plants than any other. A Clay us'd in Grafting is alſo call'd *Loam*.

LOBELIA.

The *Characters* are;

It hath a tubulous anomalous Flower, conſiſting of one Leaf, which is divided into many Parts, each being ſhaped ſomewhat like a Tongue, and are ſpread open like a Hand; this is incloſed in the Cup, which afterward becomes a ſoft oval Fruit, which is full of Juice, and ſurrounds a Nut of the ſame Shape, which has a hard Shell.

We know but one Sort of this Plant, *(viz.)*

Lobelia *fruteſcens, portulacæ folio. Plum. Nov. Gen.* Shrubby Lobelia, with a purſlane Leaf.

This Plant was named by Father *Plumier*, who diſcovered it in *America*, in Honour to Dr. *Lobel*, a learned Botaniſt, who publiſhed the Figures of a great Number of Plants at *Antwerp* in 1581. and two or three other Books of Botany before that Time.

The Seeds of this Plant were ſent to *England*, by Mr. *Cateſby* in the Year 1724. who gathered them in the *Bahama Iſlands*, where the Plants grow in Plenty, near the Shore of the Sea; and ſince that Time the Seeds have been ſent to *England* by Dr. *William Houſtoun*, who gathered them at *La Vera Cruz*, ſo that I believe the Plant is common in moſt of the warm Parts of *America*.

It is propagated by Seed, which muſt be procured from the Countries of its natural Growth, for the Plants will not produce them in *Europe*. The Seeds ſhould be ſown in Pots, filled with light ſandy Earth, and then plunged into a Hot-bed of Tanners Bark, where the Plants will come up in about three Weeks, provided the Bed is kept warm, and the Earth often watered. When the Plants are up, they ſhould have freſh Air admitted to them in very warm Weather; but if the Nights ſhould prove cold, the Glaſſes of the Hot-bed ſhould be covered every Night with Mats, to keep the Bed in a proper Temperature of Heat; the Plants ſhould alſo be frequently refreſhed with Water, but it muſt not be given in large Quantities to them; for they are very ſucculent, and ſubject to periſh with much Moiſture, eſpecially while they are young. When the Plants are about two Inches high, they ſhould be carefully taken out of the Pots in which they were ſown, and each planted in a ſeparate ſmall Pot, filled with freſh light ſandy Earth, and then plunged into the Hot-bed again, obſerving to ſhade them in the Heat of the Day, until they have taken new Root; after which Time, the Glaſſes of the Hot-bed ſhould be raiſed every Day to admit freſh Air to the Plants, in proportion to the Warmth of the Seaſon. They muſt alſo be frequently refreſhed with Water. In this Hot-bed the Plants may remain, until the middle or latter End of *September*, when they muſt be removed into the Stove, and plunged into the Tan-bed, in the warmeſt Part of the Stove; for they are very tender Plants while young, ſo muſt be kept very warm, otherwiſe they will not live thro' the Winter in this Country. They muſt alſo be frequently refreſhed with Water, but it muſt be given to them ſparingly during the Winter Seaſon; for a little too much Moiſture will rot them at that Seaſon. In the Spring following, the Plants may be ſhifted into a little larger Pots, and then plunged into a freſh Hot-bed to forward their Growth; for if they are not puſhed on while they are young, they ſeldom grow to any Size, nor will they ever flower; ſo that in order to have theſe Plants in any Beauty, they muſt be carefully managed. The Height to which theſe Plants uſually grow, is five or ſix Feet, and they divide into ſeveral Branches, which are ſucculent, as are alſo the Leaves, which are as thick and full of Moiſture, as thoſe of *Purſlane*, and being ever-green, the Plants make an agreeable Diverſity amongſt other tender Exotick Plants in the Stove; for they are too tender to be removed into the open Air in this Country, even in the warmeſt Seaſon of the Year. The Leaves of this Plant are very ſubject to contract Filth, by being kept conſtantly in the Stove; therefore they ſhould be waſhed with a Sponge every Month, to keep them clean, otherwiſe they will appear unſightly.

LOBUS ECHINATUS; Bonduc or Nicker-Tree.

The *Characters* are;

The Leaves are equally pinnated; the Flower conſiſts of one Leaf, which is cut into many deep Segments, and is almoſt of an anomalous Figure; from the Cup ariſes the Piſtillum, which becomes a rough, prickly Pod, in which are contain'd one or two hard roundiſh Seeds.

The *Species* are;

1. Lobus Echinatus *fructu flavo, foliis rotundioribus. H. L.* The yellow Nicker-Tree.
2. Lobus Echinatus *fructu cæſio, foliis longioribus. H. L.* The Aſh-colour'd Nicker, *vulgo.*

Theſe two Plants are very common in *Jamaica*, *Barbadoes*, and all the *Caribbee Iſlands*, where they climb upon the Shrubs and Trees which grow near them: The Leaves, Branches, Stems, and every Part of them are greatly beſet with Prickles, which renders it very troubleſome to paſs between them where they grow pretty cloſe.

They are preſerv'd in the warmeſt Stoves, by way of Curioſity, in *England*, but have not as yet produc'd any Flowers with us, that I have ſeen. The Seeds of this Plant are often brought over from the *Weſt-Indies*, but their Shells or Coverings are ſo very hard, as not to be eaſily broken; nor do they ever come up when ſown upon a Hot-bed as other Seeds: The only Method by which I have been capable of raiſing theſe Plants, is, to put the freſh Seeds into a freſh Hot-bed of Tanners Bark, under the Bottom of a Pot, (in which there is a Plant growing) where, from the Heat of the Bark, and the Moiſture which will gently paſs thro' the Hole at the Bottom of the Pot, and being by the Bark there detain'd, the Shell of the Fruit will ſplit, and the Seeds germinate in a ſhort Time; then they may be taken up, and planted into Pots fill'd with light freſh Earth, and plung'd into the Tanners Bark, where they will come on apace, if conſtantly ſupply'd with Water: During the Winter Seaſon they muſt be kept very warm, and often refreſhed with Water; but it muſt be given them by ſmall Quantities at a Time, for if they have too much Moiſture given them at that Seaſon, it is very apt to deſtroy them: In the Summer-time, when the Weather is warm, they will require a greater Share of Air, but they muſt never be ſet abroad even in the hotteſt Seaſon, for they are too tender to bear the open Air in our Climate, ſo that they muſt be conſtantly preſerv'd in the Stoves with *Papaws*, and other free-growing Plants which come from the ſame Country.

LOCULAMENTS, are little diſtinct Cells, or Partitions, within the Seed-Veſſels of Plants.

LONCHITIS, [ſo call'd of λόγχη, a *Lance* or *Spear*, becauſe the Leaves are ſo ſharp-pointed as to reſemble the Point of a Spear.] Rough Spleenwort.

The *Characters* are;

The Leaves are like thoſe of the Fern, *but the Pinnulæ are ear'd at their Baſe: The Fruit alſo is like that of the* Fern.

The *Species* are;

1. Lonchitis *aſpera. Ger.* Rough Spleenwort.
2. Lonchitis *aſpera major. Ger. Emac.* Greater rough Spleenwort.

The firſt of theſe Plants is very common in ſhady Woods, by the Sides of ſmall Rivulets in divers Parts of *England*: But the ſecond Sort is not quite ſo common, and has been brought into ſeveral curious Botanick Gardens from the Mountains in *Wales*. There are alſo great Variety of theſe Plants in *America*, which at preſent are Strangers in the *European* Gardens. They are ſeldom cultivated but in Botanick Gardens, for the fake of Variety, where they muſt have a moiſt Soil, and a ſhady Situation.

LONGITUDINAL VESSELS in Plants, are ſuch as are extended in Length through the woody Parts of Trees and Plants, into which the Air is ſuppos'd to enter and mix with the Juices of the Plants, and thereby augment its Bulk.

LOPPING: It is very obſervable, that moſt old Trees are hollow within; which does not proceed from the Nature of the Trees, but is the Fault of thoſe who have the Management of them, who ſuffer the Tops to grow large before they lop them, as the *Aſh*, *Elm*, *Horn-beam*, &c. and perſuade themſelves that they may have the more great Wood; but, in the mean time, don't conſider that the cutting off great Tops do endanger the Life of a Tree, or, at beſt, wound it ſo that many Trees decay more yearly in their Bodies, than the yearly Tops come to; and at the ſame Time that they furniſh themſelves with more great Wood, they do it at the Loſs of the Owner. And, indeed, tho' the *Horn-beam* and *Elm* will bear great Tops when the Body is little more than a Shell, yet the *Aſh*, if it comes to take Wet at the Head, very rarely bears more Top after the Body of the Tree decays: Therefore, if once theſe Trees decay much in the Middle, they will be worth little but for the Fire; ſo that if you find a Timber Tree decay, it ſhould be cut down in Time, that the Timber be not loſt.

The *Lopping* of young Trees, that is, at ten or twelve Years old at moſt, will preſerve them much longer, and will occaſion the Shoots to grow more into Wood in one Year, than they do in old Tops at two or three. Great Boughs ill taken off, often ſpoil many a Tree; for which Reaſon they ſhould always be taken off cloſe and ſmooth, and not parallel to the Horizon; and cover the Wound with Loam and Horſe-dung mix'd, to prevent the Wet from entring the Body of the Tree.

When Trees are at their full Growth, there are ſeveral Signs of their Decay; as, the withering or dying of many of their Top Branches; or if the Wet enters at any Knot; or they are anywiſe hollow, or diſcolour'd; if they make but poor Shoots; or if Wood-Peckers make any Holes in them.

All Sorts of reſinous Trees, or ſuch as abound with a milky Juice, ſhould be lop'd very ſparingly; for they are ſubject to decay when often cut. The beſt Seaſon for Lopping theſe Trees is ſoon after *Bartholomew-tide*, at which Time they ſeldom bleed much, and the Wound is commonly heal'd over before the cold Weather comes on.

LOTUS: Birds-foot Trefoil.

The *Characters* are;

It hath a papilionaceous Flower; the Ovary, which riſes out of the Flower-cup, afterwards becomes a Pod, ſometimes diſtinguiſh'd as it were into Cells, by tranſverſe Partitions, which are full of Seeds, for the moſt part roundiſh; to which may be added, the Leaves grow by Threes, but have two Wings or little Leaves at the Origin of their Foot-ſtalks.

The *Species* are;

1. Lotus *villoſus altiſſimus, flore glomerato. Tourn.* The talleſt hairy Birds-foot Trefoil, with a glomerated Flower.
2. Lotus *pentaphyllus ſiliquoſus villoſus. C. B. P.* Upright hoary Birds-foot Trefoil.
3. Lotus, πολυκέρατος *fruteſcens Cretica argentea, ſiliquis longiſſimis propendentibus rectis. Mor. Hiſt.* Shrubby Silver Birds-foot Trefoil of *Crete*, with long ſtrait hanging Pods.
4. Lotus *hæmorrhoidalis humilior & candidior. Tourn.* Lower and whiter Hæmorrhoidale Birds-foot Trefoil.
5. Lotus *anguſtifolius, flore luteo purpureo, ex inſula ſancti Jacobi. Hort. Amſt.* Narrow-leav'd Birds-foot Trefoil from the Iſland of St. *James*, with a purple yellow Flower.
6. Lotus *ruber, ſiliqua anguloſa. C. B. P.* Red ſquare-codded Birds-foot Trefoil, *commonly call'd* Winged Peas.
7. Lotus *ruber, ſiliqua anguloſa, folio variegato. Boerh. Ind.* Red ſquare-codded Birds-foot Trefoil, with a variegated Leaf.
8. Lotus *ſiliquis ornithopodii. C. B. P.* Birds-foot Trefoil, with Pods like a Birds-foot.

The firſt of theſe Plants is by ſome ſuppoſed to be the *Cytiſus* of *Virgil*; but with how much Juſtneſs I will not pretend to determine, ſince it is very difficult to aſcertain many of his Plants; for the greateſt Part of them are only tranſlated from *Theocritus*'s *Greek* into *Latin*, ſo that it may juſtly be ſuppoſed that *Virgil* himſelf did not know the Plants of which he wrote; and whoever has the Curioſity to know what the Plants there mention'd are, ſhould diligently ſearch for them in *Sicily* where *Theocritus* lived, and it is very probable many of them are ſtill to be found.

This Plant dies to the Ground with us every Winter, and riſes again the ſucceeding Spring; and when the Roots are ſtrong, the Shoots will be four or five Feet high, and produce in great Plenty: If it be cut while young, the *Cows* are very fond of it; but *Horſes* will not eat it unleſs they are very hungry. The Roots when ſtrong, will admit of the Shoots being cut three or four Times in a Summer, for they put out again ſoon after they are cut, and grow very ſtrong in a ſhort time; but this Plant does not come up before *April* in our Country, and commonly dies down in *October*, ſo that if it were the beſt Fodder for Cattle, it would only be obtained in Summer; for I am afraid it will hardly be of any uſe when dried.

It may be propagated from the Seeds, which are generally produced in great Plenty, and muſt be ſown very thin in Rows, at about eighteen Inches aſunder, the Beginning of *April*; and in *May*, when the Plants will be come up, the Ground ſhould be hough'd between the Rows, in order to deſtroy the Weeds, and the Plants cut up, where they are too thick (for they ſhould be eight or ten Inches apart in the Rows at leaſt); for though they will appear but weak at their firſt coming up, yet when their Roots have taken faſt hold of the Ground, they will increaſe their Strength greatly; for I have had a ſingle Root of this Plant which has been a Foot diameter over the Crown, and hath produced above a Hundred Shoots at one time.

You muſt alſo continue houghing the Ground from time to time as the Weeds are produced, which if permitted to overgrow the Plants while they are young, will certainly deſtroy them; ſo that the firſt Seaſon they muſt be managed with great Care, but afterwards when the Plants have obtain'd more Strength, they will be capable of encountering the Weeds; though then the Ground between the Rows ſhould be ſtirr'd with a Breaſt-plough after the Crop is cut down, which will greatly promote its Growth.

This Plant delights in a dry, barren, gravelly Soil, on which it will reſiſt the ſevereſt Cold of our Climate, and abide many Years.

It may alſo be propagated by planting Cuttings or Slips taken from the old Plants in *July*, when they have acquired a Hardneſs, which ſhould be planted in a moiſt, cloudy Seaſon, or water'd and ſhaded, and in a ſhort time they will take Root; but as this is difficult to perform when a Quantity is deſign'd, ſo the better way is to propagate it by Seeds.

The ſecond, third, fourth and fifth Sorts are preſerved in Gardens as Curioſities; theſe are impatient of much Cold, and muſt therefore be planted in Pots, and houſed in Winter, otherwiſe they are often deſtroy'd in our Country, eſpecially the fifth, which is much the tendereſt Plant of all the Sorts: Theſe may be all propagated by ſowing their Seeds upon a moderate Hot-bed in the Spring; and when the Plants are come up, they muſt be tranſplanted either upon another moderate Hot-bed, or into Pots, and plung'd into a Hot-bed, to promote their taking Root; after which in *May* they ſhould be remov'd into the open Air, where they muſt be placed in ſome well-ſhelter'd Situation, amongſt other exotick Plants, in which Place they may remain until the Middle or End of *October* following, when they muſt be removed into the Greenhouſe, obſerving to place them where they may have as much free Air as poſſible in mild Weather, for if they are kept too cloſely ſhut up, or ſtand under the Branches of other Trees or Plants, they are very apt to draw very weak, and decay ſoon after; they muſt alſo be often refreſh'd with Water, but it ſhould not be given them in Winter in too great Quantities, for that will rot their Roots, eſpecially of the fifth Sort, which, as I before ſaid, is the tendereſt: In the Spring they ſhould be inured very early to the open Air, into which they ſhould always be remov'd at the Beginning of *May*, or earlier, according as the Seaſon proves favourable.

Theſe may alſo be propagated by planting Cuttings, in any of the Summer Months, into a Bed of light Earth, obſerving to water and ſhade them until they have taken Root; after which they may be planted into Pots filled with light freſh Earth, and muſt be managed as was directed for the Seedling Plants. They all produce their Flowers in *June*, *July*, and *Auguſt*, and moſt of them ripen their Seeds very well in *England*: But the fifth Sort, which is the moſt rare, and produces the handſomeſt Flowers, ſeldom perfects Seeds with us, ſo that it muſt be always propagated from Cuttings; and in Winter muſt be placed ſomewhat warmer than the other Sorts, tho' not too near other Plants; and ſhould be every Year renew'd from Cuttings; for the old Plants are very ſubject to decay in Winter. The ſixth Sort is an annual Plant, which, by many People, is ſown here and there, upon the Borders of the Flower-Garden, with other ſmall Annuals, amongſt which it makes a pretty Variety.

The Flowers of this Plant (which are in Form of a *Pea-bloſſom*) are of a deep-red Colour, and are ſucceeded by Pods with four Angles or Wings (which occaſion'd their being call'd *Wing'd Peas*) containing ſeveral hard round Seeds.

It is eaſily propagated by ſowing the Seeds in *March* or *April* upon the Borders where they are to remain; for they do not thrive ſo well when tranſplanted: And they will require no farther Care than only to keep them clear from Weeds. In *June* they will begin to flower, and continue 'till *Auguſt*, when their Seeds will ripen ſoon after.

The ſeventh Sort is only a Variety of the ſixth, from which it differs in having a variegated Leaf; this Difference it commonly retains from Seeds, which is what few other Plants will do. This may be propagated as the former.

The eighth Sort is only preſerv'd in ſome Gardens, more for the Oddneſs of its Pods, (which very much reſembles a Bird's Foot) than for any particular Beauty of the Plant: But in a large Garden it may be admitted, for the ſake of Variety. This may be propagated in the ſame manner as the two former, and is alſo annual, as they are.

LOTUS ARBOR. *Vide* Celtis.

LOVE APPLE. *Vide* Lycoperſicon.

LUFFA, *Egyptian* Cucumber.

The *Characters* are;

It hath a bell-ſhaped Flower, conſiſting of one Leaf, which is divided into five Parts to the Centre: there are Male and Female Flowers on the ſame Plant; the Male Flowers are produced on ſhort Foot-ſtalks, having no Embryo's: but the Female Flowers reſt on the Top of the Embryo's, which afterwards becomes a Fruit like a Cucumber to outward Appearance, but is not fleſhy, the Inner-part conſiſting of many fibres, which are elegantly netted; and there are three Cells, which are filled with Seeds, which are almoſt of an oval Shape.

We have but one Sort of this Plant, (*viz.*)

LUFFA *Arabum*. *Tourn.* The Luffa of the Arabians.

This Plant may be propagated after the ſame Manner as *Cucumbers* and *Melons*, by ſowing of the Seeds on a Hot-bed the Beginning of *March*; and when the Plants are come up, they muſt be pricked into a freſh Hot-bed to ſtrengthen the Plants, obſerving to let them have freſh Air every Day in warm Weather, and to refreſh them frequently with Water; but it muſt not be given to them in large Quantities while they are young, or in cold Weather, leſt it deſtroy the Plants. When the Plants have four or five Leaves, they ſhould be planted out on a Hot-bed, where they are deſigned to remain, which ſhould be under Frames, and but one Plant put into each Hole; for as theſe Plants ſend forth a great Number of Side-ſhoots, ſo where they are planted too cloſe, they will entangle one into the other, and become ſo thick, as to cauſe the Fruit to drop. In the Management of theſe Plants after they are planted out for good, there muſt be the ſame Care taken as for *Melons* and *Cucumbers*, with this Difference only, that theſe require a larger Share of Air in warm Weather; otherwiſe the Vines will grow weak, and will not produce Fruit.

When the Plants have ſpread, ſo as to fill the Frames on every Side, the Frames ſhould be raiſed on Bricks, and the Ends of the Plants drawn out, that they may have room to grow; for when theſe Plants are in a vigorous State, they will ſpread eight or ten Feet; ſo that if they are confined, they will become ſo thick, as to rot the tender Branches which are covered from the Air, and there will be no Fruit produced.

The Fruit, when it is young, is by ſome People eaten, and made into Mango's, and preſerved in Pickle; but it hath a very diſagreeable Taſte, and is not accounted very wholeſome: ſo theſe Plants are ſeldom cultivated in *Europe*, except by ſuch Perſons as are curious in Botany, for Variety.

LUNARIA, [ſo call'd, of *Luna*, Lat. the *Moon*, becauſe the Seed-veſſels reſemble the Form of the Moon] Moon-wort, Satten-Flower, *or* Honeſty.

The *Characters* are;

The Flower conſiſts of four Leaves, which expand in Form of a Croſs; the Ovary (which riſes in the Centre of the Flower) becomes a compreſs'd perfectly ſmooth Fruit, divided, as it were, into two Cells by an intermediate Partition, to which adhere the parallel and membranous Valves, and fill'd with Seeds, which have commonly a broad Border, and are ſhap'd like a Kidney.

The *Species* are;

1. **Lunaria** *major, ſiliqua rotundiore. J. B.* Greater Moon-wort, with round Pods, *commonly call'd* Honeſty, *or* White Sattin.

2. **Lunaria** *major, ſiliqua longiore. J. B.* Greater Moon-wort, with a longer Pod.

3. **Lunaria** *major perennis, ſiliqua rotundiori, flore albo. Tourn.* Greater perennial Moon-wort, with a rounder Pod, and a white Flower.

4. **Lunaria**, *leucoji folio, ſiliqua oblonga majori. Tourn.* Moon-wort, with a Stock-Gilliflower Leaf, and a large oblong Pod.

5. **Lunaria** *fruticoſa perennis incana, leucoji folio. Tourn.* Shrubby perennial Moon-wort, with a Stock-Gilliflower Leaf.

6. **Lunaria** *Orientalis, leucoji folio incano, lutea patula. Jeſſieu.* Yellow ſpreading Eaſtern Moon-wort, with a Stock-Gilliflower Leaf.

7. **Lunaria** *perennis lutea, folio leucoji, ramis expanſis. Vail.* Branching yellow perennial Moon-wort, with a Stock-Gilliflower Leaf.

There are ſome other Varieties of this Plant, which are preſerv'd in curious Botanick Gardens: But thoſe here mention'd are the beſt worth cultivating, for their Beauty.

The firſt of theſe Plants is very common in moſt old Gardens in *England*, and is commonly known by the Name of *Honeſty*, or *White Sattin:* It requires very little Culture, and ſhould be ſown ſoon after the Seeds are ripe in Autumn, upon a Bed or Border of common Earth, in almoſt any Situation, (provided it be not under the Dripping of Trees) in which Place they ſhould be ſuffer'd to remain; for they ſeldom thrive well if tranſplanted; and in *May* following they will produce Flowers, and the Seeds will ripen in *Auguſt*. The Seed-veſſels of this Plant, when they are full ripe, become very tranſparent, and of the Appearance of White Satten, at which time the Branches are cut off and dry'd; after which, they are preſerv'd to place in the Chimnies of Halls and large Rooms, where they appear very agreeable.

The other Sorts may be all propagated in the ſame manner as the former, with this Difference, *viz.* That as they are ſomewhat tenderer, ſo they ſhould have a warmer Situation, otherwiſe they are ſubject to be deſtroy'd in very cold Winters: They ſhould alſo have a dry Soil, which ſhould be freſh, but not dung'd; for if the Soil be too rank, they often canker and decay, eſpecially in wet Seaſons.

Theſe Plants are all of them pretty Varieties in large Gardens where there is Room: But they are ſeldom cultivated in ſmall Places, eſpecially the two firſt Sorts, which grow pretty large, and take up too much Room. Their Flowers are not very beautiful: But for the Oddneſs of their Seed-veſſels, as alſo the different Appearances of the Plants, they may be admitted.

The third, fifth, and ſixth Sorts are perennial Plants, which may be propagated by planting Cuttings of any of them in the Summer Months, in a ſhady Border of light freſh Earth, obſerving to water them until they have taken Root; after which, they may be remov'd into the Places where they are to remain, and muſt be treated as thoſe Plants which were rais'd from Seeds.

LUPINUS: Lupine.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards turns into a Pod, that is fill'd with either plain or ſpherical Seeds. To which may be added, The Leaves grow like Fingers upon the Footſtalks.

The *Species* are;

1. **Lupinus** *ſylveſtris, purpureo flore, ſemine rotundo vario. J. B.* Wild Lupine, with a purple Flower, and round variegated Seed, *commonly call'd* The Leſſer blue Lupine.

2. **Lupinus** *anguſtifolius cœruleus elatior. Raii Hiſt.* Narrow-leav'd taller blue Lupine.

3. **Lupinus** *ſylveſtris, flore luteo. C. B. P.* The common yellow Lupine.

4. **Lupinus** *peregrinus major, vel villoſus cœruleus major. C. B. P.* Foreign greater hairy Lupine, with a large blue Flower, *commonly call'd* The great blue Lupine.

5. **Lupinus** *peregrinus major, flore incarnato. H. L.* Foreign greater Lupine, with a Fleſh-colour'd Flower, *commonly call'd* The Roſe Lupine.

6. **Lupinus** *ſativus, flore albo. C. B. P.* Garden *or* Manured Lupine, with a white Flower.

7. **Lupinus** *cœruleus minor perennis Virginianus repens. Mor. Hiſt.* Smaller perennial creeping blue Lupine of *Virginia*.

There are ſeveral other Varieties of this Plant, which are preſerv'd in ſome curious Botanick Gardens, that differ chiefly in the Colour and Size of their Flowers and Fruit; but thoſe here mention'd are ſuch as generally are preferr'd, for the Beauty of their Flowers, for which alone they are propagated in the *Engliſh* Gardens.

The firſt Sort is very common in every Garden, being ſown in the Borders of the Flower-Garden, with other hardy Kinds of annual Plants, which do not require the Aſſiſtance of a Hot-bed to bring them forward. The Seeds of this, and the common *Yellow* and *White Lupines* are very common at every Seed-ſhop, where they are ſold at a very reaſonable Price. Theſe Seeds may be ſown in *April*, *May*, and *June*, in order to continue a Succeſſion of their Flowers thro' the Summer. They muſt be ſown where they are to remain; for they ſeldom do well if tranſplanted. They love a light Soil, not too rich or moiſt; in both which they are very ſubject to rot before they perfect their Seeds.

Theſe produce their Flowers ſucceſſively in *June*, *July*, and *Auguſt*, according to the Time of their being ſown, and do commonly grow about two Feet high; ſo that if they are rightly diſpoſed amongſt other annual Plants of the ſame Growth in Borders, they make an agreeable Variety. The Seeds of theſe Plants ſhould always be ſown in dry Weather; for if there ſhould happen to be much Wet ſoon after they are put into the Ground, it commonly rots them. The blue and white Sorts have no Scent, but the yellow has a very agreeable Odour, for which it is commonly preferr'd by moſt People to the others.

The narrow leav'd tall blue *Lupine* is not ſo common in *England* as the other Sorts, tho' in *Italy* and *Spain* it is one of the moſt common: in the former of which Places it is ſown to improve the Ground which is deſign'd for Vineyards; where, when the *Lupines* are in Flower, they cut them down, and plough them into the Ground as Manure: or, if they have not Time enough to do this, they parboil the Seeds, to prevent their growing, and ſow them upon the Ground, (allowing ſixteen Buſhels to an Acre) and plough them in: ſo that in theſe Countries it is a valuable Plant.

The fourth and fifth Sorts are ſtill more rare than any of the former, and only to be found in ſome curious Gardens, eſpecially the fourth, which was formerly very common, but is now almoſt loſt amongſt us:) Theſe Plants do grow three Feet high, and ſpread out into many Branches, which are furniſh'd with fine Spikes of large Flowers, which make a handſome Appearance, and continue a long Time in Beauty. The Seeds of theſe Plants ſhould be ſown very early in the Spring, upon a warm dry Border, where they muſt remain to flower; for if they are ſown late, they ſeldom perfect their Seeds with us; therefore the better way is to ſow them in *Auguſt*, under a warm Wall or Hedge, where the Plants will come up, and endure the Cold of our ordinary Winters very well: and theſe Plants will flower early the ſucceeding Summer, and never fail to produce ripe Seeds; whereas thoſe ſown in the Spring do very often miſcarry.

The ſeventh Sort is an abiding Plant, which grows in great Plenty in *America*; from whence the Seeds have been brought into *England*, where it thrives very well, provided it be ſuffer'd to remain in the Place where it was ſown; for the Roots of this Plant commonly run very deep into the Ground, which by removing are commonly broken, after which the Plant ſeldom does well. This ſhould be ſown on a light dry Soil, in which it will thrive very well, and continue ſeveral Years, producing fine Spikes of blue Flowers: but this Sort rarely perfects its Seeds in this Country.

LUPULUS, [this Plant takes its Name of *Lupus*, Lat. a *Wolf*, becauſe the Antients had a Notion, that *Wolves* were wont to hide themſelves under this Plant] The Hop.

The *Characters* are;

It hath a creeping Root; the Leaves are rough, angular, and conjugated; the Stalks do climb and twiſt about whatever is near them; the Flowers are Male and Female on different Plants; the Male Flowers conſiſt of a Calyx, divided into five Parts, which ſurrounds the Stamina, but has no Petals to the Flower; the Female Plants have their Flowers collected into ſquamoſe Heads, which grow in Bunches; from each of the leafy Scales is produced an horned Ovary, which becomes a ſingle roundiſh Seed.

The *Species* are;

1. LUPULUS *mas. C. B. P.* The Male Hop, *commonly call'd* the Wild Hop.
2. LUPULUS *fœmina. C. B. P.* The Female *or* manur'd Hop.

Of this laſt Sort, the People who cultivate them, reckon three different Varieties; as, firſt, the long and ſquare Garlick *Hop*; the long White *Hop*; and the Oval *Hop*; all which are indifferently cultivated in *England*: But of the Male *Hop* there has been no Notice taken of any different Varieties. This Sort grows wild in Hedges in divers Parts of *England*, but is never cultivated, as being of no Uſe.

There being the greateſt Plantation of *Hops* in *Kent*, that are in any County in *England*, it is very probable, that their Method of planting and ordering them ſhould be the beſt.

As for the Choice of their *Hop-Grounds*, they eſteem the richeſt and ſtrongeſt Grounds as the moſt proper; they chuſe a warm dry Soil, that has a good Depth of hazel Mould, and if it be rocky within two or three Feet of the Surface, the *Hops* will proſper well; but they will by no means thrive on a ſtiff Clay, or ſpungy wet Land.

If it may be, chuſe a Piece of Meadow or Lay-Ground to plant *Hops* on, ſuch as has not been till'd or ſown for many Years, or an old decay'd Orchard; for Land that is worn out by long bearing of Corn, will require Abundance of Dung, to bring it into any tolerable Condition to bear a Crop of *Hops*.

They accounting new Land beſt for *Hops*, the *Kentiſh* Planters plant their *Hop-Gardens* with *Apple-trees* at a large Diſtance, and with *Cherry-trees* between; that when the Land hath done its beſt for *Hops*, which they reckon it will in about ten Years, the Trees may begin to bear. The *Cherry-trees* laſt about thirty Years; and by that Time the *Apple-trees* are large, they cut down the *Cherry-trees*.

The *Eſſex* Planters account a moory Land the propereſt for *Hops*; tho' there are ſeveral other Sorts of Soil that are eſteemed very good.

Some account that Land that has a roſſelly Top, and a brick-earthy Bottom, the beſt: A true Roſſel, or light Land, is what they generally plant in, whether it be white or black.

Moory Land is of different Sorts; ſome being fix'd and heavy, ſo as to crack in Summer; and ſome ſo light, that in dry Seaſons it will blow away with the Wind; and ſome are of a middle Conſiſtence, being compoſed of both.

Theſe Moors, for Goodneſs and Value, are according to the Nature and Goodneſs of the Soil that is underneath them; which being flung upon the Surface, will make a very good Mixture, it being beſt to fling the under Soil downward for *Hops*; becauſe they naturally root downwards, ſometimes four or five Yards deep; and therefore the deepeſt and richeſt Soil is for them.

Few are acquainted with the Value of Moors, becauſe they do not ſearch into the Bottom of them, by reaſon of the Expenſiveneſs of doing it, and the Difficulty of carrying off the Water.

If the Land be moiſt, it ought be laid up in high Ridges, and to be well drain'd, and the Drain kept clear and open, eſpecially in Winter, that the Water do not rot, or too much chill the Roots.

If the Land be ſour, or cold, it will be very much help'd by burning it; and if the Haulm and Strings of the *Hops* be burnt every Year, and ſome of the Paring or Sides of the Garden or other Earth be laid on them as they burn, and then more Haulm be laid over that, and ſo continu'd Layer upon Layer, it will make an excellent Compoſt to make the Hills with.

As to the Situation of a *Hop-Ground*, one that inclines to the South or Weſt is the moſt eligible; but if it be expoſed to the North-Eaſt or South-Weſt Winds, there ſhould be a Shelter of ſome tall Trees at a Diſtance; becauſe the North-Eaſt are apt to nip the tender Shoots in the Spring, and the South-Weſt frequently break and blow the Poles at the latter End of the Summer, and very much endanger the *Hops*.

Hops require to be planted in an open Situation, that the Air may freely paſs round and between them, to dry up and diſſipate the Moiſture, whereby they would not be ſo ſubject to Fire-blaſts, which often deſtroy the Middles of large Plantations, while the Outſides remain unhurt.

As for the Preparation of the Ground for Planting, it ſhould, the Winter before, be plough'd and harrow'd even; and then lay upon it in Heaps a good Quantity of freſh rich Earth, or well-rotted Dung and Earth mix'd together, ſufficient to put half a Buſhel in every Hole to plant the *Hops* in, unleſs the natural Ground be very freſh.

Then lay a Line acroſs it, from the Hedge, in which Knots have been tied, at the Diſtance you deſign your *Hop-hills* to be at, about eight or nine Feet Diſtance the whole Length of the Ground, and place a ſharp-pointed Stick at every Knot; then lay aſide the Line, and with two forked Sticks of about eight or nine Feet long, you may from that firſt Row ſet out the whole Ground, by applying the two Forks to two of the Sticks which were firſt ſet up, and placing another Row at the Ends where the forked Sticks meet triangular-wiſe; then you ſhould dig a Hole at every Stick about a Foot and an half wide, and fill it full of the good Earth you brought in.

If you plough the Ground with Horſes between the Hills, it will be beſt to plant them in Squares Checquer-wiſe; but the *Quincunx* Form is the moſt beautiful, and it will alſo be better for the *Hop*: But if the Ground be ſmall, that it may be done with the Breaſt-Plough or Spade, it will do very well; but which Way ſoever you make uſe of, a Stake ſhould be ſtuck down at all the Places where the Hills are to be made.

Perſons ought to be very curious in the Choice of the Plants and Sets, as to the Kind of *Hop*; for if the *Hop-Garden* be planted with a Mixture of ſeveral Sorts of *Hops*, that ripen at ſeveral Times, it will cauſe a great deal of Trouble, and be a great Detriment to the Owner.

The two beſt Sorts are the white and the grey Bind; the latter is a large ſquare *Hop*, more hardy, and is the more plentiful Bearer, and ripens later than the former.

There is alſo another Sort of the white Bind, which ripens a Week or ten Days before the common; but this is tenderer, and a leſs plentiful Bearer: but it has this Advantage, it comes firſt to Market.

But if three Grounds, or if three diſtant Parts of one Ground be planted with theſe three Sorts, there will be this Conveniency, that they may be pick'd ſucceſſively as they become ripe.

The Sets ought to be procur'd out of Grounds that are intirely of the ſame Sort you would have; they ſhould be five or ſix Inches long, with three or more Joints or Buds on them, all the old Bind and hollow Part of the Set being cut off.

If there be a Sort of *Hop* you value, and would increaſe Plants and Sets from, the ſuperfluous Binds may be laid down when the *Hops* are tied, cutting off the Tops, and burying them in the Hill; or when the *Hops* are dreſs'd, all the Cuttings may be ſaved, and laid in Rows in a Bed of good Earth; for almoſt every Part will grow, and become a good Set the next Spring.

Some have tried to raiſe a *Hop-Ground* by ſowing Seeds; but that turns to no Account, becauſe that Way is not only tedious, but the *Hops* ſo produced are commonly of different Kinds, and many of them wild and barren.

As to the Seaſons of planting *Hops*, the *Kentiſh* Planters beſt approve the Months of *October* and *March*, both which ſucceed very well; but the common Sets are not to be had in *October*, unleſs from ſome Ground that is to be digg'd up and deſtroy'd; and likewiſe there is ſome Danger that the Sets may be rotted, if the Winter prove very wet: But the moſt uſual Time of procuring them is in *March*, when the *Hops* are cut and dreſs'd.

As to the Manner of planting the Sets, you ſhould put five good Sets in every Hole with a Setting-ſtick; one is to be placed in the Middle, and the reſt round about, ſloping, the Tops meeting at the Center: They muſt ſtand even with the Surface of the Ground: Let them be preſs'd cloſe with the Hand, and cover'd with fine Earth; and a Stick ſhould be placed on each Side the Hill, to ſecure it.

The Ground being thus planted, all that is to be done more that Summer, is to keep the Hills clear from Weeds, and to dig up the Ground about the Month of *May*, and to gather up the Stones, if more are turn'd up by digging, to raiſe a ſmall Hill round about the Plants: And in *June*, you muſt twiſt the young Binds or Branches together into a Bunch or Knot; for if they are tied up to ſmall Poles the firſt Year, in order to have a few *Hops* from them, it will not countervail the weakening of the Plants.

A Mixture of Compoſt or Dung being prepared for your *Hop-Ground*, the beſt Time for laying it on, if the Weather prove dry, is about *Michaelmas*, that the Wheels of the Dung-cart may not injure the *Hops*, nor furrow the Ground: If this be not done then, you muſt be obliged to wait till the Froſt has harden'd the Ground, ſo that it will bear the Dung-cart: And this is alſo the Time to carry on your new Poles, to recruit thoſe that are decay'd, and to be caſt out every Year.

If you have good Store of Dung, the beſt Way will be to ſpread it in the Alleys, all over the Ground, and to dig it in the Winter following. The Quantity they will require, will be forty Loads to an Acre, reckoning about thirty Buſhels to the Load.

If you have not Dung enough to cover all the Ground in one Year, you may lay it on one Part one Year, and on the reſt in another, or a third; for there is no Occaſion to dung the Ground after this Manner oftener than once in three Years.

Thoſe who have but a ſmall Quantity of Dung, uſually content themſelves with laying on about twenty Loads upon an Acre every Year; this they lay only on the Hills, either about *November*, or in the Spring; which laſt ſome account the beſt Time, when the *Hops* are dreſs'd, to cover them after they are cut; but if it be done at this Time, the Compoſt or Dung ought to be very well rotted and fine.

As to the dreſſing of the *Hops*; when the *Hop-Ground* is dug in *January* or *February*, the Earth about the Hills, and very near them, ought to be taken away with a Spade, that you may come the more conveniently at the Stock to cut it.

About the End of *February*, if the *Hops* were planted the Spring before, or if the Ground be weak, they ought to be dreſs'd in dry Weather; but elſe, if the Ground be ſtrong, and in Perfection, the Middle of *March* will be a good Time; and the latter End of *March*, if it be apt to produce over-rank Binds, or the Beginning of *April*, may be ſoon enough.

Then having, with a Iron Picker, clear'd away all the Earth out of the Hills, ſo as to make the Stock bare to the principal Roots, with a ſharp Knife you muſt cut off all the Shoots which grew up with the Binds the laſt Year; and alſo all the young Suckers, that none be left to run in the Alley, and weaken the Hill. It will be proper to cut one Part of the Stock lower than the other, and alſo to cut that Part low that was left higheſt the preceding Year. By purſuing this Method, you may expect to have ſtronger Binds, and alſo keep the Hill in good Order.

In dreſſing thoſe *Hops* that have been planted the Year before, you ought to cut off both the dead Tops and the young Suckers, which have ſprung up from the Sets, and alſo to cover the Stocks with a Hive with fine Earth a Finger's Length in Thickneſs.

About the Middle of *April* the *Hops* are to be Poled, when the Shoots begin to ſprout up; the Poles muſt be ſet to the Hills deep into the Ground, with a ſquare Iron Picker or Crow, that they may the better endure the Winds: Three Poles are ſufficient for one Hill. Theſe ſhould be placed as near the Hill as may be, with their bending Tops turn'd outwards from the Hill, to prevent the Binds from intangling; and a Space between two Poles ought to be left open to the South, to admit the Sun-beams.

The Poles ought to be in Length ſixteen or twenty Feet more or leſs, according as the Ground is in Strength; and great Care is to be taken not to over-pole a young or weak Ground; for that will draw the Stock too much, and weaken it. If a Ground be over-poled, you are not to expect a good Crop from it; for the Branches which bear the *Hops* will grow very little, till the Binds have over-reach'd the Poles, which they cannot do when the Poles are too long. Two ſmall Poles are ſufficient for a Ground that is young.

If you wait till the Sprouts or young Binds are grown to the Length of a Foot, you will be able to make a better Judgment where to place the largeſt Poles; but if you ſtay till they are ſo young as to fall into the Allies, it will be injurious to them, becauſe they will intangle one with another, and will not claſp about the Pole ſo readily.

Maple or *Aſpen* Poles are accounted the beſt for *Hops*, on which they are thought to proſper beſt, becauſe of their Warmth; or elſe, becauſe the climbing of the *Hop* is furthered by Means of the Roughneſs of the Bark. But for Laſtingneſs, *Aſhen* or *Willow* Poles are preferable: But *Cheſnut* Poles are the moſt durable of all.

If after the *Hops* are grown up, you find any of them have been under-poled, taller Poles may be placed near thoſe that are too ſhort, to receive the Binds from them.

As to the Tying of *Hops*, the Buds that do not claſp of themſelves to the neareſt Pole when they are grown to three or four Feet high, muſt be guided to it by the Hand, turning them to the Sun, whoſe Courſe they will always follow. They muſt be bound with wither'd Ruſhes, but not ſo cloſe as to hinder them from climbing up the Pole.

This you muſt continue to do till all the Poles are furniſh'd with Binds, of which two or three are enough for a Pole; and all the Sprouts and Binds that you have no Occaſion for, are to be pluck'd up: But if the Ground be young, then none of theſe uſeleſs Binds ſhould be pluck'd up, but ſhould be wrapt up together in the Middle of the Hill.

When the Binds are grown beyond the Reach of your Hands, if they forſake the Poles, you ſhould make uſe of a Stand-Ladder in tying them up.

Some adviſe, that if the Binds be very ſtrong, and overgrow the Poles very much, to ſtrike off their Heads with a long Switch, to increaſe their branching below.

Towards the Latter-end of *May*, when you have made an End of tying them, the Ground muſt have the Summer Digging: this is done by caſting up with the Spade ſome fine Earth into every Hill; and a Month after this is done, you muſt pare the Alleys with a Shovel, and make the Hills up to a convenient Bigneſs.

It is not at all to be doubted but that a thorough Watering would be of very great Advantage to *Hops* in a hot dry Summer: But it is ſo much Charge and Trouble to do this, that unleſs you have a Stream at hand, to flow the Ground, it is ſcarce practicable.

When the *Hops* blow, you ſhould obſerve if there be any wild barren Hills among them, and mark them, by driving a ſharpen'd Stick into every ſuch Hill, that they may be digged up, and replanted.

Hops, as well as other Vegetables, are liable to Diſtempers and Diſaſters, and, among the reſt, to the Fen.

The Reverend Dr. *Hales*, in his excellent Treatiſe of *Vegetable Staticks*, treating of *Hops*, gives us the following Account of the State of *Hops* in *Kent*, in the Year 1725, that he receiv'd from Mr. *Auſtin* of *Canterbury*, which is as follows:

In Mid-*April* not half the Shoots appear'd above Ground; ſo that the Planters knew not how to pole them to the beſt Advantage.

This Defect of the Shoot, upon opening the Hills, was found to be owing to the Multitude and Variety of Vermin that lay preying upon the Roots; the Increaſe of which, was imputed to the long and almoſt uninterrupted Series of dry Weather for three Months before. Towards the End of *April* many of the *Hop-Vines* were infeſted with Flies.

About the 20th of *May* there was a very unequal Appearance, ſome Vines being run ſeven Feet, others not above three or four; ſome juſt tied to the Poles, and ſome not viſible: and this diſproportionate Inequality in their Size, continued thro' the whole Time of their Growth.

The Flies now appear'd upon the Leaves of the forwardeſt Vines, but not in ſuch Numbers here, as they did in moſt other Places. About the Middle of *June* the Flies increaſed, yet not ſo as to endanger the Crop; but in diſtant Plantations they were exceedingly multiplied, ſo as to ſwarm towards the End of the Month.

June the 27th ſome Specks of Fen appear'd. From this Day to the 9th of *July* was very dry Weather. At this Time, when it was ſaid that the *Hops* in moſt Parts of the Kingdom look'd black and ſickly, and ſeem'd paſt Recovery, ours held it out pretty well, in the Opinion of the moſt ſkilful Planters.

The great Leaves were indeed diſcolour'd, and a little wither'd, and the Fen was ſomewhat increaſed. From the 9th of *July* to the 23d, the Fen increaſed a great deal; but the Flies and Lice decreaſed, it raining much daily. In a Week more, the Fen, which ſeem'd to be almoſt at a Stand, was conſiderably increaſed, eſpecially in thoſe Grounds where it firſt appear'd.

About the Middle of *Auguſt* the Vines had done growing both in Stem and Branch; and the forwardeſt began to be in the Hop, the reſt in Bloom: the Fen continued ſpreading where it was not before perceiv'd; and not only the Leaves, but many of the Burrs were alſo tainted with it.

About the 20th of *Auguſt* ſome of the *Hops* were infected with the Fen, and whole Branches corrupted by it. Half the Plantations had pretty well eſcaped hitherto, and from this Time the Fen increaſed but little: But ſeveral Days Wind and Rain in the following Week, ſo diſtorted them, that many of them began to dwindle, and at laſt came to nothing; and of thoſe that then remain'd in Bloom, ſome never turn'd to *Hops*; and of the reſt which did, many of them were ſo ſmall, that they very little exceeded the Bigneſs of a good thriving Burr.

We did not begin to pick till the 8th of *September*, which is eighteen Days later than we began the Year before: The Crop was little above two hundred on an Acre round, and not good. The beſt *Hops* ſold this Year at *Way-hill* for ſixteen Pounds the Hundred.

The Rev. Dr. *Hales*, in his aforeſaid Treatiſe, gives us an Account of the following Experiment that he made on *Hop-Vines*: He tells us, That in *July* he cut off two thriving *Hop-Vines* near the Ground, in a thick ſhady Part of the Garden, the Pole ſtill ſtanding; he ſtript the Leaves off from one of theſe Vines, and ſet their Stems in known Quantities of Water in little Bottles; that with Leaves imbibed in a twelve Hours Day, four Ounces; and that without Leaves three-fourths of an Ounce.

He took another *Hop-pole* with its Vines on it, and carried it out of the *Hop-Ground* into a free and open Expoſure; theſe imbibed and perſpired as much more as the former in the *Hop-Ground*: which is, doubtleſs, the Reaſon why the *Hop-Vines* on the Outſides of the Gardens, where they are moſt expoſed to the Air, are ſhort and poor, in Compariſon of thoſe in the Middle of the Ground; *viz.* becauſe being much dried, their Fibres harden ſooner, and therefore they cannot grow ſo kindly as thoſe in the Middle of the Ground, which, by Shade, are always kept moiſter, and more ductile.

The ſame curious Author proceeds as followeth: Now there being 1000 Hills in an Acre of Hop-Ground, and each Hill having three Poles, and each Pole three Vines, the Number of Vines will be 9000, each of which perſpiring four Ounces, the Sum of all the Ounces perſpired by an Acre in a 12 Hours Day will be 36000 Ounces = 15750000 Grains = 62007 Cube Inches, or 220 Gallons which divided by 6272640, the Number of ſquare Inches in an Acre, it will be found that the Quantity of Liquor perſpired by all the Hop Vines will be equal to an Area of Liquor as broad as an Acre, and $\frac{1}{101}$ Part of an Inch deep, beſides what evaporated from the Earth.

And this Quantity of Moiſture in a kindly State of the Air, if daily carried off, is a ſufficient Quantity to keep the *Hops* in an healthy State: But in a rainy moiſt State of Air, without a due Mixture of dry Weather, too much Moiſture hovers about the *Hops*, ſo as to hinder, in ſome meaſure, the kindly Perſpiration of the Leaves, whereby the ſtagnating Sap corrupts, and breeds mouldy Fen, which often ſpoils vaſt Quantities of flouriſhing Hop-Grounds.

This was the Caſe in the Year 1723, when for ten or fourteen Days almoſt continual Rains fell, about the latter half of *July*, after four Months dry Weather; upon which the moſt flouriſhing and promiſing *Hops* were all infected with Mould or Fen in their Leaves and Fruit, while the then poor and unpromiſing *Hops* eſcaped, and produced Plenty; becauſe they being ſmall, did not perſpire ſo great a Quantity as others; nor did they confine the perſpired Vapour, ſo much as the large thriving Vines did in their ſhady Thickets.

This Rain on the then warm Earth made the Graſs ſhoot out as faſt as if it were in a Hot-bed; and the Apples grew ſo precipitantly, that they were of a very flaſhy Conſtitution, ſo as to rot more remarkably than had ever been remember'd.

The Planters obſerve, that when a Mould or Fen has once ſeiz'd any Part of the Ground, it ſoon runs over the whole, and that the Graſs and other Herbs under the *Hops* are infected with it; probably, becauſe the ſmall Seeds of this quick-growing Mould, which ſoon come to Maturity, are blown over the whole Ground; which ſpreading of the Seed, may be the Reaſon why ſome Grounds are infected with Fen for ſeveral Years ſucceſſively, *viz.* from the Seeds of the laſt Year's Fen. Might it not then be adviſeable to burn the Fenny *Hop-Vines*, as ſoon as the *Hops* are pick'd, in hopes thereby to deſtroy ſome of the Seed of the Mould?

Mr. *Auſten* of *Canterbury* obſerves Fen to be more fatal to thoſe Grounds that are low and ſhelter'd, than to the high and open Grounds; to thoſe that are ſhelving to the North, than to thoſe ſhelving to the South; to the Middle of Grounds, than to the Outſides; to the dry and gentle Grounds, than to the moiſt and ſtiff Grounds.

This was very apparent throughout the Plantations where the Land had the ſame Workmanſhip and Help beſtow'd upon it, and was wrought at the ſame Time. But if in either of theſe Caſes there was a Difference, it had a different Effect; and the low and gentle Grounds, that lay neglected, were then ſeen leſs diſtemper'd than the open and moiſt, which were carefully managed and look'd after.

The Honey-Dews are obſerv'd to come about the 11th of *June*, which by the Middle of *July* turn the Leaves black, and make them ſtink.

The ſaid Dr. *Hales* relates, that in the Month of *July* (the Seaſon for *Fire-blaſts*, as the Planters call them) he has ſeen the Vines in the Middle of the *Hop-Ground* ſcorch'd up almoſt from one End of a large Ground to the other, when a hot Gleam of Sunſhine has come immediately after a Shower of Rain, at which Time the Vapours are all ſeen with the naked Eye, but eſpecially with reflecting Teleſcopes, to aſcend ſo plentifully as to make a clear and diſtinct Object become immediately very dim and tremulous: nor was there any dry gravelly Vein in the Ground along the Courſe of this Scorch: it was therefore, probably, owing to the much greater Quantity of ſcorching Vapours in the Middle, than the Outſides of the Ground; and that being a denſer Medium, it was much hotter than a more rare Medium.

And, perhaps, the great Volume of aſcending Vapours might make the Sun-beams converge a little towards the Middle of the Ground, that being a denſer Medium, and thereby increaſe the Heat conſiderably: for he obſerved, that the Courſe of the ſcorched *Hops* was in Lines at right Angles to the Sun-beams about Eleven o'Clock, at which Time the hot Gleam was.

The *Hop-Ground* was in a Valley which ran from South-Weſt to North-Eaſt; and, to the beſt of his Remembrance, there was but little Wind, and that in the Courſe of the Scorch: But had there been ſome other gentle Wind, either North or South, it is not improbable but that the North Wind gently blowing the Volume of riſing Wreak on the South Side of the Ground, that Side might have been moſt ſcorch'd; and ſo *vice verſa*.

As to particular Fire-blaſts which ſcorch here and there a few *Hop-Vines*, or one or two Branches of a Tree without damaging the next adjoining; what Aſtronomers obſerve, may hint to us no very improbable Cauſe of it, *viz.* They frequently obſerve, (eſpecially with reflecting Teleſcopes) ſmall ſeparate Portions of pellucid Vapours floating in the Air, which, tho' not viſible to the naked Eye, are yet conſiderably denſer than the circumambient Air: and Vapours of ſuch a Degree of Denſity, may very probably either acquire ſuch a ſcalding Heat from the Sun, as will ſcorch what Plants they touch, eſpecially the more tender.

An Effect, which the Gardeners about *London* have too often found, to their Coſt, when they have incautiouſly put Bell-glaſſes over their *Cauliflowers* early in a froſty Morning, before the Dew was evaporated off them; which Dew being raiſed by the Sun's Warmth, and confined within the Glaſs, did there form a denſe, tranſparent, ſcalding Vapour, which burnt and kill'd the Plants.

Or perhaps the upper or lower Surface of theſe tranſparent, ſeparate, flying Volumes of Vapours may, among the many Forms they revolve into, ſometimes approach ſo near to an Hemiſphere, or Hemi-cylinder, as thereby to make the Sun-beams converge, ſo as often to ſcorch the more tender Plants they ſhall fall on:

And ſometimes alſo Parts of the more hardy Plants and Trees, in proportion to the greater or leſſer Convergency of the Sun's Rays.

The Learned *Boerhaave*, in his *Theory of Chymiſtry*, p. 245, obſerves, That thoſe Clouds which appear in Summer-time, are, as it were, ſo many Mirrours, and occaſion exceſſive Heat. Theſe cloudy Mirrours are ſometimes round, ſometime concave, polygonous, *&c.* When the Face of Heaven is cover'd with ſuch white Clouds, the Sun ſhining among them, muſt of Neceſſity produce a vehement Heat; ſince many of his Rays, which would otherwiſe, perhaps, never touch our Earth, are hereby reflected to us. Thus, if the Sun be on one ſide, and the Clouds on the oppoſite one, they will be perfect Burning-glaſſes. And hence the Phænomena of Thunder.

I have ſometimes (continues he) obſerved a kind of hollow Clouds full of Hail and Snow, during the Continuance of which the Heat was extreme; ſince, by ſuch Condenſation, they were enabled to reflect more ſtrongly. After this, came a ſharp Cold, and then the Clouds diſcharged their Hail in great Quantity, to which ſucceeded a moderate Warmth. Frozen concave Clouds therefore, by their great Reflexions, produce a vigorous Heat; and the ſame, when reſolved, exceſſive Cold.

From which the Rev. Dr. *Hales* obſerves as follows:

Hence we ſee that Blaſts may be occaſion'd by the Reflexions of the Clouds, as well as by the above-mention'd Refraction of denſe tranſparent Vapours.

But to return to the Management of *Hops*:

About the Middle of *July* Hops begin to blow, and will be ready to gather about *Bartholomew-tide*. A Judgment may be made of their Ripeneſs, by their ſtrong Scent, their Hardneſs, and the Browniſh Colour of their Seed.

When by theſe Tokens they appear to be ripe, they muſt be pick'd with all the Expedition poſſible; for if at this Time a Storm of Wind ſhould come, it would do them great Damage, by breaking the Branches, and bruiſing and diſcolouring the *Hops*. And it is very well known, that *Hops* being pick'd green and bright, will ſell for a third Part more than thoſe which are diſcolour'd and brown.

The moſt convenient Way of picking them, is into a long ſquare Frame of Wood call'd a *Binn*, with a Cloth hanging on Tenter-hooks within it, to receive the *Hops* as they are pick'd.

This Frame is compoſed of four Pieces of Wood join'd together, ſupported by four Legs, with a Prop at each End to bear up another long Piece of Wood, placed at a convenient Height over the Middle of the Binn; this ſerves to lay the Poles upon, which are to be pick'd.

This Binn is commonly eight Feet long, and three Feet broad: two Poles may be laid on it at a time, and ſix or eight Perſons may work at it, three or four on each Side.

It will be beſt to begin to pick the *Hops* on the Eaſt or North Side of your Ground, if you can do it conveniently; this will prevent the South-Weſt Wind from breaking into the Garden.

Having made choice of a Plot of the Ground containing eleven Hills ſquare, place the Binn upon the Hill which is in the Centre, having five Hills on each Side; and when theſe Hills are pick'd, remove the Binn into another Piece of Ground of the ſame Extent, and ſo proceed till the whole *Hop-Ground* is finiſh'd.

When the Poles are drawn up to be pick'd, you muſt take great Care not to cut the Binds too near the Hills, eſpecially when the *Hops* are green, becauſe it will make the Sap to flow exceſſively.

And if the Poles do not come up without Difficulty, they ſhould be raiſed by a Piece of Wood in the nature of a Lever, having a forked Piece of Iron with Teeth on the Inſide, faſten'd within two Feet of the End.

The *Hops* muſt be pick'd very clean, *i. e.* free from Leaves and Stalks; and, as there ſhall be Occaſion, two or three times in a Day the Binn muſt be emptied into a *Hop-bag* made of coarſe Linen Cloth, and carried immediately to the Oaſt or Kiln, in order to be dried: for if they ſhould be long in the Binn or Bag, they will be apt to heat, and be diſcolour'd.

If the Weather be hot, there ſhould no more Poles be drawn than can be pick'd in an Hour; and they ſhould be gather'd in fair Weather, if it can be, and when the *Hops* are dry: this will ſave ſome Expence in Firing, and preſerve their Colour better when they are dried.

The beſt Method of Drying *Hops*, is with Charcoal on an Oaſt or Kiln cover'd with Hair-cloth, of the ſame Form and Faſhion that is uſed for drying of *Malt*. There is no need to give any particular Directions for the Making it; ſince every Carpenter or Bricklayer, in thoſe Countries where *Hops* grow, or *Malt* is made, knows how to build them.

The Kiln ought to be ſquare, and may be of ten, twelve, fourteen, or ſixteen Feet over at the Top, where the *Hops* are laid, as your Plantation requires, and your Room will allow. There ought to be a due Proportion between the Height and the Breadth of the Kiln and the Beguels of the Steddle where the Fire is kept; *viz.* if the Kiln be twelve Feet ſquare on the Top, it ought to be nine Feet high from the Fire, and the Steddle ought to be ſix Feet and an half ſquare, and ſo proportionable in other Dimenſions.

The *Hops* muſt be ſpread even upon the Oaſt a Foot thick, or more, if the Depth of the Curb will allow it; but Care is to be taken not to over-load the Oaſt, if the *Hops* be green or wet.

The Oaſt ought to be firſt warm'd with a Fire before the *Hops* are laid on; and then an even ſteady Fire muſt be kept under them: it muſt not be too fierce at firſt, leſt it ſcorch the *Hops*; nor muſt it be ſuffer'd to ſink or ſlacken, but rather be increaſed till the *Hops* be nearer dried, leſt the Moiſture or Sweat which the Fire has raiſed, fall back or diſcolour them. When they have lain about nine Hours, they muſt be turn'd, and in two or three Hours more they may be taken off the Oaſt. It may be known when they are well dried, by the Brittleneſs of the Stalks, and the eaſy falling off of the *Hop-Leaves*.

The *Dutch* and *Flemings* have another Method of drying their *Hops*: They make a ſquare Kiln or Room about eight or ten Feet wide, built of Brick or Stone, having a Door at one Side, and a Fire-place in the Middle of the Room, on the Floor, about thirteen Inches wide within, and thirteen Inches high, in Length from the Mouth of it almoſt to the Back-part of the Kiln, a Paſſage being left juſt enough for a Man to go round the End of it. This they call a Horſe, ſuch as is commonly made in Malt-kilns, the Fire paſſing out at Holes at each Side, and at the End of it.

The Bed or Floor, on which the *Hops* lie to be dried, is placed about five Feet high above; about that is a Wall, near four Feet high, to keep the *Hops* from falling.

A Window is made at one Side of the upper Bed, to ſhove off the dry *Hops* down into a Room prepared to receive them. The Beds are made of Laths or Rails ſawn very even, lying a quarter of an Inch diſtant from one another, with a Croſs-beam in the Middle, to ſupport them; the Laths are let in even with the Top of the Beam, and this keeps them even in their Places. This they call an Oaſt.

The *Hops* are laid on this Bed by Baſkets full, without any Oaſt-cloth, beginning at one End, and ſo going on till all is cover'd half a Yard thick, without treading them; then they even them with a Rake, that they may lie of an equal Thickneſs.

This being done, they kindle the Fire below, either of Wood or Charcoal; but the latter is accounted the better Fewel for *Hops*: The Fire is kept as much as may be at an equal or conſtant Heat, and only at the Mouth of the Furnace; for the Air will ſufficiently diſperſe it.

They do not ſtir them till they are throughly dried, *i. e.* till the Top is as fully dried as the Bottom; but if they find any Place not to be ſo dry as the reſt, (which may be known by reaching over them with a Stick or Wand, and touching them in ſeveral Places,) they obſerve where they do not rattle, and where they do; and where they do not rattle, they abate them there, and diſpoſe of them where the Places were firſt dry.

They know when they are throughly dry, by the Brittleneſs of the inner Stalk, if it be ſhort when it is rubb'd; which when they find, they take out the Fire, and ſhove out the *Hops* at the Window, that is made for that Purpoſe, into the Room made to receive them, with a Coal-rake made with a Board at the End of a Pole; and then go in at the Door below and ſweep up the *Hops* and *Seeds* that fall thro', and put them to the other *Hops*; then they lay another Bed of green *Hops*, and renew the Fire, and proceed as before.

This Method is diſapproved by ſome, becauſe (they ſay) the *Hops* lying ſo thick, and not being turn'd, the under Part of them muſt needs dry before the upper, and the Fire paſſing thro' the whole Bed to dry the uppermoſt, muſt neceſſarily over-dry and much prejudice the greateſt Part of the *Hops* both in Strength and Weight, beſides the unneceſſary Expence of Firing, which muſt be long continued to dry throughly ſo many together.

Therefore ſome have improved on this Method, and adviſed to make the Kiln much as is before directed as to the *Dutch* Way.

Firſt, To make a Bed of flat Ledges about an Inch thick, and two or three Inches broad, ſawn and laid acroſs one another the flat Way, Chequer-wiſe, at about three or four Inches Diſtance one from the other, the Edges being ſo enter'd one into the other, that the Floor may be even and ſmooth: This Bed may be made to reſt on two or three Joiſts, ſet Edgewiſe, to ſupport it from ſinking.

This Bed is to be cover'd with large double Tin, ſolder'd together at each Joint; and the Ledges muſt be ſo order'd, before they are laid, that the Joints of the Tin may always lie over the Middle of the Ledge, the Bed being wholly cover'd over with Tin, Boards muſt be fitted about the Edges of the Kiln, to keep up the *Hops*; but one Side muſt be made to remove, that the *Hops* may be ſhoved off as before.

On this Bed or Floor of Tin, the *Hops* may be turn'd without ſuch Hazard or Loſs, as upon the Hair-cloth, and alſo it will require a leſs Expence of Fewel; and beſides, any Sort of Fewel will ſerve in this Kiln, as well as Charcoal, becauſe the Smoak does not paſs thro' the *Hops*, as it does the former Ways: But then Care is to be taken, that there be Paſſages made for it at the ſeveral Corners and Sides of the Kiln.

It is found by Experience, that the turning of the *Hops*, tho' it be after the moſt eaſy and beſt Manner, is not only an Injury and Waſte to the *Hops*, but alſo an Expence of Fewel and Time; becauſe they require as much Fewel, and as long a Time to dry a ſmall Quantity, by turning them, as a large one.

Now this may be prevented, by having a Cover (to be let down and raiſed at Pleaſure) to the upper Bed whereon the *Hops* lie.

This Cover may alſo be Tinn'd, by nailing ſingle Tin Plates over the Face of it, ſo that when the *Hops* begin to dry, and are ready to burn, *i. e.* when the greateſt Part of their Moiſture is evaporated, then the Cover may be let down within a Foot or leſs of the *Hops*, (like a Reverberatory) and will reflect the Heat upon them, ſo that the Top will ſoon be as dry as the Lowermoſt, and every *Hop* be equally dried.

As ſoon as the *Hops* are taken off the Kiln, lay them in a Room for three Weeks or Month, to cool, give, and toughen; for if they are Bagg'd immediately, they will powder; but if they lie a while, (and the longer they lie the better, provided they be cover'd cloſe with Blankets to ſecure them from the Air) they may be Bagg'd with more Safety, as not being liable to be broken to Powder in treading, and this will make them bear treading the better; and the harder they are trodden, the better they will keep.

The common Method of Bagging is as follows: They have an Hole made in an upper Floor, either round or ſquare, large enough to receive a Hop-bag, (which conſiſts of four Ells and an half of Ell-wide Cloth, and alſo contains ordinarily Two hundred and an half of *Hops*;) they tie a Handful of *Hops* in each lower Corner of the Bag, to ſerve as Handles to it; and they faſten the Mouth of the Hole, ſo placed that the Hoop may reſt upon the Edges of the Hole.

Then he that is to tread the *Hops* down into the Bag, treads the *Hops* on every Side, another Perſon continually putting of them in as he treads them, till the Bag is full; which being well fill'd and trodden, they unrip the Faſtening of the Bag to the Hoops, and let it down, and cloſe up the Mouth of the Bag, tying up a Handful of *Hops* in each Corner of the Mouth, as was done in the lower Part.

Hops being thus pack'd, if they have been well dried, and laid up in a dry Place, they will keep good ſeveral Years: But Care muſt be taken that they be neither deſtroy'd nor ſpoil'd by the Mice making their Neſts in them.

The Crop of *Hops* being thus beſtow'd, you are to provide for another; firſt by taking care of the Poles againſt another Year, which are beſt to be laid up in a Shed, having firſt ſtripp'd off the Haulm from them: But if you have not that Conveniency, ſet up three Poles in the Form of a Triangle, or ſix Poles (as you pleaſe) wide at Bottom; and having ſet them into the Ground, with an Iron Picker, and bound them together at Top, ſet the reſt of your Poles about them: and being thus diſpoſed, none but thoſe on the Outſide will be ſubject to the Injuries of the Weather; for all the inner Poles will be kept dry, unleſs at the Top; whereas if they were on the Ground, they would receive more Damage in a Fortnight, than by their ſtanding all the reſt of the Year.

In the Winter-time, provide your Soil and Manure for the *Hop-Ground* againſt the following Spring.

If the Dung be rotten, mix it with two or three Parts of common Earth, and let it incorporate together till you have Occaſion to make uſe of it in making your *Hop-hills*; but if it be new Dung, then let it be mix'd as before, till the Spring come Twelve-months; for new Dung is very injurious to *Hops*.

Dung of all Sorts was formerly more commonly made uſe of than now it is, eſpecially when rotted and turn'd to Mould; and they who have no other Manure muſt uſe it: Which if they do, Cows or Hogs Dung, or human Ordure mix'd with Mud may be a proper Compoſt; becauſe *Hops* delight moſt in a Manure that is cool and moiſt.

Some recommend Chalk or Lime as the beſt Manure, except in cold Lands; and in ſuch, Pigeons Dung will do beſt; a little of which laid to a Hill, and ſo mix'd that it may not be too hot in a Place, is of great Advantage.

LUTEOLA, [ſo call'd of *Luteus*, Lat. *Yellow*, becauſe it is uſed in dying a yellow Colour] Weld, Would, Yellow-weed, *or* Dyers-weed.

The *Characters* are;

The Leaves are oblong and intire; it hath an anomalous Flower, conſiſting of many diſſimilar Leaves; the Fruit is globular, hollow, and divided into three Parts.

The *Species* are;

1. LUTEOLA *herba, ſalicis folio. C. B. P.* Common Weld.
2. LUTEOLA *minima, polygalæ folio. D. du Bois. Raii Syn.* Smalleſt Weld, with a Milkwort Leaf.

The firſt of theſe Plants is very common in *England*, growing upon dry Banks and the Tops of Walls and Buildings, almoſt every-where; but the ſecond Sort is very rare: This was found near *Tunbridge-Wells* by *Charles Du Bois*, Eſq; ſeveral Years ſince.

The common *Weld* is accounted a rich Dyers Commodity, and is of great Advantage, conſidering the ſmall Expence of its Culture: It will grow upon the pooreſt Sort of Land, provided it be dry; tho' upon a middling Soil it will grow much larger. The Seeds of this Plant ſhould be ſown the Beginning of *Auguſt*, ſoon after ripe; when it will come up with the firſt moiſt Weather, and will grow very ſtrong the ſame Autumn, provided it be ſown by itſelf; for moſt People ſow it with Corn, which is very wrong; for that hinders its Progreſs greatly, and occaſions the Loſs of one whole Year. When the Plants are come up pretty ſtrong, you ſhould hough them, (as is practiſed with *Turnips*) in order to deſtroy the Weeds, as alſo to cut up the Plants where they grow too thick, which will greatly improve them; and the ſucceeding Spring, if the Ground produces many Weeds, you ſhould give it a ſecond Houghing in *April*, which will preſerve it clean from Weeds; for after that the *Weld* will grow, and prevent the Weeds from coming to a Head afterwards.

You muſt be very cautious in the gathering of it, that the Seed be not over-ripe, ſo as to fall out, and that neither the Stalk or Seed be under-ripe; becauſe if it be, both will be ſpoil'd. It muſt be pull'd up and bound in little Handfuls, and ſet to dry, as you do *Flax*, and then houſe it carefully, that you ſhake not out the Seed, which is eaſily beat out, and ſhould be ſown (as was before directed) ſoon after it is ripe.

This Seed is commonly ſold for about Ten Shillings *per* Buſhel, or more; a Gallon of which will ſow an Acre; for it is very ſmall.

There are ſome who recommend the ſowing this Seed in the Spring, mixing it with a Crop of *Barley* or *Oats*, and only harrow'd in with a Buſh, or roll'd with a Roller. But this is not a good Method; for the *Barley* or *Oats* will ſtarve the *Weld*, and make it very poor: and, many Times, the Seeds which are ſown in the Spring do not grow, or not come up, till the Autumn following; whereas that ſown in the Beginning of *Auguſt*, rarely fails to come up ſoon after, and will be much ſtronger, and fit to pull the ſucceeding Summer, when the other is always two Years before it is pull'd. The *Dyers* uſe it for dying of bright Yellows and Lemon Colours. It is much ſown in *Kent*, eſpecially about *Canterbury*, and often yields from Forty Shillings to Ten or Twelve Pounds an Acre.

LYCHNIS, [ſo call'd of λύχνος, a *Candle* or *Light*, becauſe the Flowers of this Plant imitate the Flame or Rays of Light] Campion.

The *Characters* are;

The Leaves are whole, and grow oppoſite by Pairs upon the Stalks: The Cup of the Flower is whole, and either tubulous or ſwelling, and for the moſt part furrow'd: The Flower conſiſts of five Leaves, which expand in form of a Clove-Gilliflower, *and are generally Heart-ſhaped: The Ovary, which riſes in the Center of the Calyx, becomes a conical Fruit, which is wrapt up in the Flower-cup, and has commonly one Cell, which is fill'd with Seeds, which are roundiſh, angular, and Kidney-ſhaped.*

The *Species* are;

1. LYCHNIS *coronaria Dioſcoridis, ſativa, flore dilute rubente. C. B. P.* Garden *or* Roſe Campion, with a pale-red Flower.
2. LYCHNIS *coronaria Dioſcoridis, ſativa, flore rubro, velut flammeo fulgens. C. B. P.* Roſe Campion, with a flaming red-colour'd Flower.
3. LYCHNIS *coronaria ſativa multiplex. C. B. P.* The double Roſe Campion.
4. LYCHNIS *coronaria ſativa Dioſcoridis, flore albo. C.B.P.* The ſingle White Roſe Campion.
5. LYCHNIS *umbellifera montana Helvetica. Zan.* Umbelliferous Mountain Campion of *Helvetia*.
6. LYCHNIS *alba multiplex. C. B. P.* Double White Campion, *commonly called*, The Double Batchelor's Button.
7. LYCHNIS *purpurea multiplex. C. B. P.* Double Red Campion, *commonly called*, The Double Red Batchelor's Button.
8. LYCHNIS *pratenſis, flore laciniato pleno. Mor. Hiſt.* The Double Meadow Campion, with a jagged Flower, *commonly called*, The Double Ragged Robin.
9. LYCHNIS *hirſuta, flore coccineo, major. C. B. P.* The ſcarlet *Lychnis*, Nonſuch, Jeruſalem Croſs, *or* Flower of Conſtantinople.
10. LYCHNIS *hirſuta, flore incarnato, major. C. B. P.* Great Hairy Campion, with a Fleſh-colour'd Flower, *commonly called*, The pale *Lychnis* of Conſtantinople.
11. LYCHNIS *Chalcedonica, flore pleno miniato, ſeu aurantiaco. Mor. Hiſt.* The Double Scarlet *Lychnis*, or Flower of Conſtantinople.
12. LYCHNIS, *ſeu ſaponaria, flore pleno. Tourn.* Double Soapwort, *vulgo*.
13. LYCHNIS *ſylveſtris, quæ Been album, vulgo. C. B. P.* Wild Campion Spatling Poppy, *or* White Behen of the Shops.
14. LYCHNIS *ſylveſtris viſcoſa anguſtifolia rubra. C. B. P.* Red German Catchfly.
15. LYCHNIS *ſylveſtris viſcoſa anguſtifolia rubra, flore pleno.* Red German Catchfly, with a double Flower.
16. LYCHNIS *orientalis, bupleuri folio. T. Cor.* Eaſtern Campion, with a Hare's-ear Leaf.
17. LYCHNIS *facie Auriculæ urſi. C. B. P.* Campion with the Face of an Auricula.
18. LYCHNIS *maritima ſaxatilis, folio anacampſerotis. T. Cor.* Maritime Rocky Campion, with an Orpine Leaf.

19. Lychnis *noctiflora anguſtifolia odorata. Tourn.* Night-flower'd ſweet-ſcented Campion, with a narrow Leaf.

20. Lychnis *fruteſcens myrtifolia, Beën albo ſimilis. C. B. P.* Shrubby Myrtle-leaved Campion, like the White Behen.

21. Lychnis *ſegetum rubra, foliis perfoliatæ. C. B. P.* Red Corn-Campion, with thorough Wax Leaves.

22. Lychnis *ſupina Sicula, calyce ampliſſimo ſtriato. Tourn.* Low Sicilian Campion, with a large ſtreak'd Flower-cup.

23. Lychnis *ſylveſtris viſcoſa anguſtifolia rubra altera. C. B. P.* Another narrow-leav'd wild Campion, with a viſcous Stalk, and red Flowers.

24. Lychnis *viſcoſa purpurea latifolia lævis. C. B. P.* Purple viſcous Campion, with a broad ſmooth Leaf, *commonly called*, Lobel's Catchfly.

25. Lychnis *viſcoſa alba latifolia lævis. C. B. P.* White flowering broad-leav'd Catchfly.

26. Lychnis *hirſuta minor, flore variegato. Tourn.* Small hairy Campion, with a variegated Flower, *commonly called*, Dwarf Lychnis.

27. Lychnis *Hiſpanica, folio kali, multiflora. Tourn.* Spaniſh many-flower'd Campion, with a Glaſs-wort Leaf.

28. Lychnis *Hiſpanica, valerianæ rubræ folio, purpuraſcente flore. Tourn.* Spaniſh Campion, with a red Valerian Leaf, and a purpliſh Flower.

29. Lychnis *ſegetum meridionalium annua, hirſuta, floribus rubris, uno verſu diſpoſitis. Mor. Hiſt.* Corn annual hairy Campion, with red Flowers diſpoſed on one Side of the Stalk.

30. Lychnis *ſylveſtris alba, ſpica reflexa. Bot. Monſp.* White wild Campion, with a reflex'd Spike.

The firſt, ſecond, and fourth Sorts are very common in moſt *Engliſh* Gardens: Theſe are very hardy Plants, and eaſily propagated either by parting of their Roots, or from Seed; if by parting the Roots, it ſhould be done about the latter End of *Auguſt*, or the Beginning of *September*, that they may take Root before the cold Weather comes on: They may be planted in any Situation, provided they have a light dry Soil. If you would propagate them from Seeds, they ſhould be ſown in *March*, upon a Bed of freſh light Earth; and in *May* the Plants ſhould be tranſplanted into another Bed of the like freſh Earth, at about ſix Inches Diſtance from each other; obſerving to water and ſhade them until they have taken Root; after which, they will require no farther Culture than to keep them clear from Weeds.

At *Michaelmas* following, theſe Plants may be placed into the large Borders of the Pleaſure-Garden; where, the Summer following, they will produce their Flowers in *June* and *July*; and ſoon after, their Seeds will ripen, which, if permitted to ſhed on the Ground, will riſe the ſucceeding Spring, without any Care.

Theſe Plants, when intermix'd with others of the like Size, do make an agreeable Variety during the Seaſon of Flowering.

The *Double Roſe Campion* is ſomewhat nicer, and requires more Care in its Culture than any of the former: This never produces any Seeds, and is therefore only to be propagated by parting the Roots; the beſt Time for which is in *Auguſt*, when the Heads taken off ſhould be planted on a Bed of light freſh Earth; and if the Seaſon ſhould prove dry, they muſt be water'd and ſhaded until they have taken Root: After which, they muſt be kept clear from Weeds; and during the Winter Seaſons, they ſhould be ſkreen'd from exceſſive Rains; for too much Moiſture at that Seaſon, very often rots them. In *March* they may be taken up with a Ball of Earth to their Roots, and tranſplanted either into the Borders of the Flower-Garden, or in Pots fill'd with light freſh Earth, and placed where they may have the Morning Sun till Eleven o' Clock, in which Situation they will thrive better than when they have more of the Sun. In dry Weather they muſt be frequently water'd: But you ſhould never let them have too much Wet; for that will canker and rot them, as will alſo a very rich Soil. This Plant commonly grows about two Feet high, and produces a great Number of beautiful red Flowers in *June* and *July*, which continue a long Time, for which they are greatly eſteemed.

The *Umbelliferous Mountain Campion* is nearly akin to the before-mention'd Sorts, but produces its Flowers in an Umbel upon the Top of the Stalks, which are of a bright red Colour, and make a very pretty Variety in a Garden: This ſeldom grows above eight or nine Inches high, therefore it ſhould be placed amongſt Flowers of the ſame Growth; it delights in a light freſh undung'd Soil, and ſhady Situation, and may be propagated either from Seeds, which it commonly affords in great Plenty, or from Slips, as the before-mentioned Sorts.

The *Red* and *White Batchelor's Button* are very hardy Plants, in reſpect to Cold: But if they are ſuffer'd to remain long in a Place unremoved, they are very ſubject to rot and decay. They never produce Seeds, ſo are propagated only by parting of their Roots, which may be done either in *September*, or in the Beginning of *March*: But the former Seaſon is preferable; for they will then be well rooted in the Ground before the dry Weather of the Spring comes on, whereby they will be out of Danger from that; whereas thoſe planted in the Spring, if the Weather ſhould prove dry ſoon after, will ſtarve, and be very weak, unleſs frequently water'd: Theſe commonly grow above two Feet high, and produce their Flowers in *June* and *July*: They love a freſh loamy Soil, which ſhould not be dung'd, and to have a Situation to the Morning Sun, in which they will thrive better than in a more open Expoſure.

The *Double Ragged Robin* is alſo increaſed by parting the Roots in Autumn: This Plant muſt have a moiſt Soil, and ſhady Situation, where it will thrive exceedingly: But in a hot dry Soil it ſeldom does well. It produces its Flowers about the ſame Time as the former, and is very proper for ſhady cold Borders, where few other Plants will thrive.

The *Single Scarlet Lychnis* may be either propagated by ſowing the Seeds, or parting the Roots: if from Seeds, it ſhould be ſown on a Bed of light Earth in the Beginning of *March*; and when the Plants are come up pretty ſtrong, (which is commonly in *May*) they ſhould be tranſplanted out into Nurſery-beds at about ſix Inches Diſtance each Way, obſerving to water and ſhade them until they have taken Root; after which they will require no farther Care, but only to keep them clear from Weeds until *Michaelmas*; at which time they may be removed into the Borders of the Flower-Garden, where the next Summer they will produce very ſtrong Stems of Flowers: but if you would propagate them by parting the Roots, it ſhould be done in *September*, (as was directed for the fore-mention'd Sorts.) This Plant will grow in almoſt any Soil or Situation, but does beſt in a middling loamy Soil, and an open Expoſure.

The *Double Lychnis* or *Nonſuch* is only propagated by parting the Roots, or planting the Cuttings of its Flower-ſtems, which, if water'd and ſhaded, will take Root very well, and make good Plants. The beſt Seaſon for parting the Roots is in *September*: but for planting the Cuttings, *July* is the moſt proper Seaſon: in doing of this, you ſhould take only the lower Parts of the Flower-ſtems, which generally ſucceed much better than the extreme Parts: the Cuttings ſhould have three Joints, two of which ſhould be placed in the Ground, and the third only left above Ground, from which the Shoot will be produced, and make a good Plant; by which Method this beautiful Flower may be propagated much faſter than from the Root alone.

This Plant delights in a freſh light Soil, which is not too dry, where it will produce very ſtrong Stems, and riſe about three Feet high. This flowers in *July*, and if the Seaſon does not prove very hot, will continue in Beauty a whole Month, for which it is greatly eſteem'd.

The *Double Sopewort* is a Plant of no great Beauty; and being a very great Runner in Gardens, has been almoſt excluded from all curious Gardens: but as it is a Plant which requires very little Culture, ſo it may be admitted to have a Place in ſome abject Part of the Garden. This is propagated by its running Roots, which ſhould be tranſplanted in *October*, and may be placed in any Soil and Situation; but ſhould never ſtand near any other Plants, for it will over-run and deſtroy them. It may be planted under Trees in large Avenues, *&c.* where it will thrive very well, and in *Auguſt* will produce large Bunches of double Flowers, which are very proper to place in Chimnies, *&c.* or in Baſons among other Flowers, where it will make a fine Appearance; and were it leſs common, it would be more eſteem'd than it is at preſent.

The *Spattling Poppy* or *White Behen* is a very common Plant in the Fields, in moſt Parts of *England*, and is rarely cultivated in Gardens; but thoſe who have a mind to preſerve it for Medicinal Uſes, may propagate it by ſowing the Seeds in *March*, on a Bed of common Earth, where the Plants will eaſily riſe, and if kept clear from Weeds, will ſoon overſpread the Ground, and will continue for ſeveral Years.

The *Red German Catchflies*, both ſingle and double, are eaſily propagated by parting the Roots, which ſhould be done in Autumn; for if it be perform'd in the Spring, the dry Weather, which uſually happens at that Seaſon, greatly retards their Growth, whereby their Flowers are never ſo ſtrong, nor produced in ſuch Plenty, as when they are removed in Autumn. Theſe produce their Flowers in Spikes upon clammy Stalks, which grow about a Foot high, and flower in *April* and *May*: that with ſingle Flowers always is the earlieſt, but the double Sort continues longeſt in Flower.

The ſingle Sort may be propagated by Seeds, which ſhould be ſown in *March*, upon a Bed of light Earth; and when the Plants come up, they ſhould be tranſplanted into Nurſery-beds about ſix Inches aſunder, where they will require no farther Care than to keep them clear from Weeds, and in very dry Weather to give them a little Water, and at *Michaelmas* they may be removed where they are deſigned to remain.

The ſingle flower'd Sort is not near ſo beautiful as the double, and therefore hardly worth propagating, ſince the double is very eaſily multiplied, eſpecially if planted in a moiſt light Soil, in which it will thrive exceedingly, and produce ſtrong Flowers. This Sort is very proper to Plant in Pots, to adorn ſmall Court-yards at the Time of its Flowering.

The ſixteenth and nineteenth Sorts are pretty Varieties in a Garden; and as they take up but little Room, and are not very nice in their Culture, they may have a Place amongſt other Flowers of the ſame Growth. Theſe are propagated by ſowing their Seeds in *March*, upon a Bed of light freſh Earth; and when the Plants are come up, they ſhould be tranſplanted into a Nurſery-bed, as the former, and at *Michaelmas* may be removed into the Borders of the Flower-Garden, where they are to remain. Theſe Plants commonly grow about two Feet high; but as their Leaves are narrow, and the Flower-ſtems ſtand erect, ſo they take up very little Room, and their Roots will continue ſeveral Years, and annually produce large Quantities of Flowers: theſe delight in a freſh light dry Soil.

The ſeventeenth is a biennial Plant, and is only propagated by Seeds, which ſhould be ſown on a Border of freſh light Earth in *March*; and when the Plants are come up, they ſhould be tranſplanted: ſome of which ſhould be planted in Pots fill'd with the ſame freſh Earth, that they may be removed under ſhelter in Winter; for it often happens, in ſevere Winters, that thoſe Plants which are placed in the open Air are deſtroy'd; for which Reaſon it is adviſeable to have ſome of the Plants in ſhelter to ſecure the Kind.

The other Plants may be planted in a Nurſery-bed, as was directed for the former Kinds, where they may remain until *Michaelmas*; at which time they ſhould be tranſplanted into warm Borders, and in a light dry Soil, where they will endure the Cold of our ordinary Winters very well, and flower very ſtrong the ſucceeding Summer. This Plant commonly grows three Feet high, and is apt to branch out pretty much, therefore ſhould be ſupported by Stakes, otherwiſe the Wind often breaks down the Flower-ſtems before the Seeds are perfected.

The eighteenth Sort is alſo tender: this may be propagated by ſowing the Seeds in the ſame Manner as the former; and when the Plants come up, ſome of them ſhould be planted into Pots fill'd with light freſh undung'd Earth, that they may be ſhelter'd in Winter; and the reſt planted into a Nurſery-bed, which ſhould be prepared of freſh light Earth that has not been dung'd; for Moiſture and Richneſs in the Soil will deſtroy them: in this Place they may remain till *Michaelmas*, when they ſhould be removed into very warm Borders; and if they are placed quite cloſe to the Wall, where it is commonly very dry, they will ſucceed the better; as alſo planted on a dry rubbiſhy Soil; for the Leaves of this Plant are very thick and ſucculent, as are all the Stems, ſo that it is as impatient of Wet as the *Sedum* or *Houſeleek*; and I do not certainly know whether this Plant would not bear a greater Share of Cold, if it was planted upon an old Wall or Building, where it might be always dry, and not have too much Nouriſhment from the Ground. The following Summer this Plant will produce its Flowers, (which, tho' they are not very beautiful, yet for the Oddneſs of the Plant it may have a Place in a good Garden) and the Seeds generally ripen in *Auguſt*: it may alſo be propagated by planting Cuttings in any of the Summer Months, which will take Root, and may be afterwards managed as the Seedling Plants.

The *Myrtle-leav'd ſhrubby Campion* may be propagated by Seeds as the former, or increaſed by planting Cuttings in any of the Summer Months, which will ſoon after take Root, and become ſtrong Plants; ſome of which ſhould be planted in Pots, that they may be ſhelter'd in Winter, for fear of being loſt; tho' they will endure the Cold of our Climate very well, if planted on a dry Soil. There is no great Beauty in this Plant; but it is preſerved for Variety-ſake in ſeveral curious Gardens.

The twenty-ſeventh and twenty-eighth Sorts are abiding Plants, and may be propagated either by Seeds or parting their Roots, in the Manner which has been directed for the *Roſe Campion*, and other Sorts before mention'd: they are very hardy, and will grow upon almoſt any Soil or Situation: they produce their Flowers in *June* and *July*, and their Seeds ripen ſoon after.

The other Sorts are all of them annual Plants, which may be eaſily propagated by ſowing their Seeds either in *March* or *Auguſt*, when the Plants will ſoon come up, and may be tranſplanted, while young, into the Places where they are deſign'd to remain; or the Seeds may be ſcatter'd in Patches upon the large Borders of the Flower-Garden; and when the Plants are come up, they may be thinn'd, leaving ſome of the ſtrongeſt to flower in the ſame Places, and the other Plants may be removed into other Parts of the Garden.

Thoſe Plants which come up in Autumn will be much larger, and flower earlier and ſtronger than thoſe ſown in the Spring, and will produce good Seeds; whereas it ſometimes happens, in bad Seaſons, that thoſe ſown in the Spring do often decay before their Seeds are perfected; tho' it is a good Method to ſow at both Seaſons, becauſe hereby there will be a Succeſſion of their Flowers, and two Chances for good Seeds.

The *Dwarf Lychnis* has been by ſome recommended to be ſown for Edgings in large Gardens; but I think it by no means proper for that Purpoſe; for when the Plants grow very cloſe together, they draw up weak, ſo that in hard Rains they are beaten down flat to the Ground, and the Flowers ſeldom continue long in Beauty, ſo that it does not afford any Pleaſure above a Fortnight or three Weeks at moſt, after which it appears very unſightly; for when it is in Seed, the Weight of that forces it down upon the Ground; but when the Plants grow ſingly, they will be much larger and ſtronger, and continue longer in Flower.

The two Sorts of *Lobel's Catchfly* have been long cultivated in Gardens, and the Seeds are commonly ſold at the Seed-ſhops in *London*: theſe grow upright to the Height of ſixteen or eighteen Inches, (if ſown in the Autumn, but thoſe which are ſown in the Spring ſeldom grow ſo large) and produce pretty Tufts of Flowers upon the Tops of the Branches in Form of an Umbel, which continue a long time in Perfection, and are pretty Ornaments in a large Garden.

The twenty-ſecond Sort ſpreads upon the Ground, and therefore muſt be allow'd more Room than the former: theſe Plants ſhould be planted two Feet aſunder, otherwiſe they will run into each other, (eſpecially ſuch as are ſown in the Autumn) ſo that in wet Weather they are ſubject to rot and decay. This produces a great Number of beautiful red Flowers, which make a very agreeable Appearance during their Seaſon of Flowering.

There are a great number of Sorts more than I have here mention'd, which are preſerv'd in curious Botanick Gardens for Variety-ſake; but as moſt of them are Plants of little Beauty, ſo I thought it needleſs to enumerate them in this Place, ſince thoſe here mention'd are the beſt worth propagating in a Flower-Garden.

But before I quit this Article, I ſhall beg Leave to add two Plants to this Genus by Way of Appendix, tho', according to their Characters, they do not, in Strictneſs, belong to it, differing in their Flowers from the *Lychnis's*, which have their Flowers cut to the Bottom into five Parts; whereas the Flowers of theſe Kinds are intire, conſiſting of one Leaf: which Diſtinction being not very great, the modern Botaniſts have thought proper to diſtinguiſh them by the Name of *Lychnidea*, which ſignifies ſomething like a *Lychnis*. Of this Genus we have, at preſent, but two Species which are common in *England*, *viz.*

1. Lychnidea *Virginiana, holoſtei ampliore folio, floribus umbellatis purpureis. Rand.* Virginian Lychnidea, with a broad Stitchwort Leaf, and purple Flowers growing in an Umbel.

2. Lychnidea *Caroliniana, floribus quaſi umbellatim diſpoſitis, foliis lucidis craſſis acutis. Martyn. Hiſt. Plant. Rar.* Carolina Lychnidea, with Flowers growing almoſt in an Umbel, and thick ſhining ſharp-pointed Leaves.

Theſe two Plants are propagated either by Cuttings, or parting of their Roots; for they do not produce Seed in this Country. The beſt Time to part their Roots is in the Beginning of *April*, juſt before they begin to ſhoot; when you ſhould take up the Roots, and after having pared off the outer Part of the Ball of Earth, ſo as to ſee where the Heads divide diſtinctly, you muſt with a Knife ſeparate them, ſo as to preſerve ſome Buds upon the Top of each Diviſion; then you may plant them either into Borders of freſh Earth, or Pots fill'd with good freſh loamy Earth, obſerving to water them, if the Seaſon ſhould prove dry, until they have taken Root; after which, thoſe in the Borders will require no farther Care, but only to clear them from Weeds, and when the Flower-ſtems advance, to ſupport them with Sticks; but thoſe in the Pots muſt be frequently water'd in dry Weather, otherwiſe they will ſoon decay.

The firſt of theſe Plants produces its Flowers in *May*; but the ſecond ſeldom flowers till the Middle of *June*, ſo that they ſucceed each other. During their Seaſon of flowering, they make a very handſome Appearance, and are very proper to cut for Baſons and Flower-pots to adorn Chimnies and Halls at that Seaſon: but the ſecond Sort is a much fairer Plant than the firſt; the Stems of this Sort riſe higher, and are ſtronger: the Flowers are larger, and of a deeper Colour; but it is not quite ſo hardy as the firſt, which will endure the ſevereſt Cold of our Climate in the open Air, whereas this muſt be ſhelter'd in hard Winters, otherwiſe it will be in Danger of ſuffering by the Cold; tho' in our common Winters it will endure abroad very well.

Theſe Plants may alſo be propagated by Cuttings, which ſhould be taken from the old Plants in *May* or *June*, and planted on a Border of freſh light Earth, obſerving to water and ſhade them, until they have taken Root; after which, you muſt obſerve to keep them clear from Weeds, and in very dry Weather repeat watering them as often as they ſhall want it; and when they have obtain'd ſufficient Strength to remove, they may be tranſplanted either into Pots or Borders, where they are to remain. By this Method you may greatly increaſe theſe Plants, which will ſupply the Defect of Seeds.

LYCOPERSICON, [of λύκος, a *Wolf*, and *Perſica*, Lat. a *Peach*] Love-Apples.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which expands in a circular Order, as doth that of the Nightſhade; *the Style afterwards becomes a roundiſh ſoft fleſhy Fruit, which is divided into ſeveral Cells, wherein are contain'd many flat Seeds.*

The *Species* are;

1. Lycopersicon *Galeni. Ang.* Yellow Love-Apple.
2. Lycopersicon *Galeni, fructu rubro. Boerh. Ind.* Love-Apple, with a red Fruit.
3. Lycopersicon *fructu ceraſi rubro. Tourn.* Love-Apple, with a red Cherry-ſhaped Fruit.
4. Lycopersicon *fructu ceraſi luteo. Tourn.* Love-Apple, with a yellow Cherry-ſhaped Fruit.
5. Lycopersicon *fructu ſtriato duro. Tourn.* Love-Apple, with a hard channell'd Fruit.
6. Lycopersicon *fructu rubro non ſtriato. Inſt. R. H.* Love-Apple with a ſmooth red Fruit.
7. Lycopesicon *fructu albo. Inſt. R. H.* Love-Apple with a white Fruit.
8. Lycopersicon *Americanum arboreſcens, ampliſſimis foliis angulatis. Plum. Cat.* American tree-like Love-Apple, with large angular Leaves.

Theſe Plants are propagated by ſowing their Seeds on a moderate Hot-bed in *March*; and when come up, they ſhould be tranſplanted into another moderate Hot-bed, at about three Inches Diſtance from each other, obſerving to ſhade them until they have taken Root; after which they muſt have frequent Waterings, and a large Share of freſh Air; for if they are too much drawn while young, they ſeldom do well afterwards.

In *May* theſe Plants ſhould be tranſplanted either into Pots fill'd with rich light Earth, or into the Borders of the Flower-Garden, obſerving to water and ſhade them until they have taken Root; and as the Branches are extended, they ſhould be ſupported with Sticks; otherwiſe, when the Fruit begins to grow, it will preſs them down, and break them.

Thoſe Plants which are placed in Pots, ſhould be often water'd, otherwiſe they will come to little, (for they are very droughty Plants) but when they are planted in a rich moiſt Soil, they will grow to a prodigious Size, and produce large Quantities of Fruit; which in Autumn, when they are ripe, make an odd Figure, but the Plants emit ſo ſtrong an Effluvium, as render them unfit to ſtand near a Habitation, or any Place that is much frequented; for upon their being bruſh'd by the Cloaths, they ſend forth a very ſtrong diſagreeable Scent.

The *Italians* and *Spaniards* eat theſe Apples, as we do Cucumbers, with Pepper, Oil, and Salt, and ſome eat them ſtew'd in Sauces, *&c.* but conſidering their great Moiſture and Coldneſs, the Nouriſhment they afford muſt be bad. They are call'd by the *Portugueſe* and *Spaniards* Tomato's. The firſt of theſe Plants is the Sort directed for Medicinal Uſe, by the *College* in their *Diſpenſatory*.

The ſixth and ſeventh Sorts are annual Plants, which periſh ſoon after they have perfected their Fruit. Theſe muſt be ſown in the Spring on a moderate Hot-bed to bring them forward, and afterward treated in the ſame Manner as thoſe Sorts above mentioned.

The eighth Sort will riſe to the Height of ſix or eight Feet, and become woody. This Sort is propagated by Seeds, which ſhould be ſown on a Hot-bed in the Spring; and when the Plants are come up about two Inches high, they muſt be tranſplanted into a moderate Hot-bed, obſerving to water and ſhade them until they have taken new Root; after which Time they ſhould have a large Share of free Air in warm Weather, to prevent their drawing up weak. When the Plants have obtain'd a good Share of Strength, they ſhould be carefully taken up with Earth to their Roots, and planted into Pots filled with light rich Earth, and placed in a ſhady Situation until they have taken Root; when they may be removed into a warm Situation, where they may remain Abroad in the open Air, until the Middle or End of *September*, when they muſt be removed into the Conſervatory, and placed where they may have a moderate Share of Warmth in cold Weather; by which Method the Plants may be preſerved thro' the Winter, and the following Summer they will produce Fruit.

LYCOPUS, [λυκόπȣς, of λύκος, a *Wolf*, and πȣ̃ς, a *Foot*, q. d. *Wolf's-foot*; becauſe the Ancients fancied, that the Leaves of this Plant reſembled the Foot of a Wolf] *commonly call'd* Water-Horehound.

This Plant grows in great Plenty on moiſt Soils by the Sides of Ditches, in moſt Parts of *England*, but is never cultivated in Gardens; ſo that it would be needleſs to ſay any thing more of it in this Place.

LYSIMACHIA, [this Plant was ſo call'd of *Lyſimachus*, the Son of a King of *Sicily*, who is ſaid to have firſt found it] Loſe-ſtrife.

The *Characters* are;

The Leaves (which are intire and oblong) are produced ſometimes by Pairs, or three or four at each Joint of the Stalk; the Flower conſiſts of one Leaf, which expands in a circular Order, and is cut into ſeveral Segments at the Top; the Fruit is globular, and opens at the Top, incloſing many Seeds fix'd to the Placenta.

The *Species* are;

1. Lysimachia *lutea major, quæ Dioſcoridis. C. B. P.* Common yellow Loſe-ſtrife *or* Willow-herb.
2. Lysimachia *lutea major, quæ Dioſcoridis, foliis quaternis. C. B. P.* Greater yellow Loſe-ſtrife *or* Willow-herb, with four Leaves at each Joint.
3. Lysimachia *bifolia, flore luteo globoſo. C. B. P.* Loſe-ſtrife, with two Leaves growing at each Joint, and yellow Flowers growing in round Heads.
4. Lysimachia *Orientalis anguſtifolia, flore purpureo. T. Cor.* Narrow-leav'd Eaſtern Loſe-ſtrife, with a purple Flower.
5. Lysimachia *Hiſpanica ſpicata, ſalicis folio, flore albo. Jeſſ.* Spaniſh Loſe-ſtrife, with white Flowers growing in Spikes.

The firſt of theſe Plants is pretty common by Ditch-ſides, in many Parts of *England*, and is ſeldom cultivated in Gardens, tho' it is not a very deſpicable Plant; for it produces large Spikes of fine yellow Flowers in *July*; for which Reaſon it may be admitted into a cold wet Part of the Garden, where few others will thrive, whereby many a Spot of Ground may be render'd agreeable, which often produces little but groſs Weeds. This Plant may be taken up in the Spring, from the native Places of its Growth, and tranſplanted where you intend it ſhould grow, and it will ſoon increaſe, by its creeping Roots, to what Quantity you pleaſe. This Plant is order'd in the *College Diſpenſatory* for Medicinal Uſe.

The ſecond Sort is not a Native of our Country; but when tranſplanted hither, thrives equally with the former. This loves a moiſt rich Soil; and for Variety may be admitted into a Garden.

The third Sort is found in the North of *England* in great Plenty. This Plant is not very proper for a Garden; for the Roots ſpreading very far under Ground, will over-run whatever Plants ſtand near it; nor are the Flowers of any Beauty.

The fourth Sort is a biennial Plant, which produces fine Spikes of ſmall purple Flowers in *June*, and the Seeds are ripe in *Auguſt*.

This Plant may be propagated by ſowing the Seeds ſoon after they are ripe, (for if they are kept until the Spring, they ſeldom grow) upon a warm Border of light Earth; and when the Plants are come up, they ſhould be tranſplanted into a Border of ſtrong Earth, where they may have the Morning Sun; in which Place they ſhould remain to flower; for it is a Plant that does not care to be often removed.

The fifth Sort is an abiding Plant, which may be propagated by parting its Roots. The beſt Seaſon for this Work is at *Michaelmas*, when the Leaves begin to decay. It ſhould be planted in a moiſt Soil, and a ſhady Situation, or muſt be often water'd, otherwiſe it will not produce Flowers. It may alſo be propagated by ſowing the Seeds in the ſame Manner as the former: but thoſe Plants which riſe from Seeds ſeldom flower until the ſecond Year; whereas thoſe propagated from Offſets will flower the ſucceeding Year. Theſe produce their Flowers in *July*; and their Seeds ripen in *September*.

MACALEB. *Vide* Ceraſus.

MADDER. *Vide* Rubia Tinctorum.

MAGNOLIA, The Laurel-leaved Tulip-Tree, *vulgo*.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſeveral Leaves, which are placed in a circular Order, from out of the Cup ariſes the Pointal, which afterwards becomes a hard conical Fruit with many Tubers or Riſings; in each of which is contained one hard Nut, which, when emitted, hangs by a long String.

The *Species* are;

1. **Magnolia** *lauri folio ſubtus albicante. Cateſb.* The leſſer Laurel-leaved Tulip-Tree, or ſweet-flowering Bay.
2. **Magnolia** *altiſſima, lauro-ceraſi folio ampliſſimo, flore ingenti candido. Cateſb. Hiſt. Nat. Car.* Commonly called the Laurel-leaved Tulip-Tree, or Carolina Laurel.
3. **Magnolia** *ampliſſimo flore albo, fructu cæruleo. Plum. Nov. Gen.* Magnolia, or American Laurel, with very large Leaves, a white Flower, and blue Fruit.

The firſt of theſe Plants is common in *Virginia* and *Carolina*, where it uſually riſes to the Height of fifteen or ſixteen Feet; but in *England* it is very rare at preſent. The largeſt Plant of this Kind which I have obſerved in *England*, is in the Garden of Mr. *Peter Colinſon*, at *Peckham* in *Surrey*; which, altho' not above five Feet high, hath produced Flowers for ſeveral Years paſt. The Wood of this Tree is white and ſpongy, covered over with a white Bark; the Leaves are in Shape like thoſe of the common *Bay*, of a pale green Colour, and white on their Backſides. In *May* they begin to produce their Flowers, which are white and very fragrant; theſe are continued two Months or more, during which Time the Woods are perfumed with their Odour. When the Petals of the Flowers are decayed, the Pointal becomes a conical Fruit, about the Size of a large Walnut, thick-ſet with Knobs or Riſings, from each of which, when the Fruit is ripe, are diſcharged flat Seeds, of the Size of Kidney-Beans, having a Kernel within a thin Shell, covered with a red Skin. Theſe red Seeds, when diſcharged from their Cells, fall not to the Ground; but are ſupported by ſmall white Threads of about two Inches in Length, which make a very beautiful Appearance. The Fruit is at firſt green; when ripe, red; and when declining, turns brown. This Tree grows naturally in moiſt Places, and often in ſhallow Water; and, what is very extraordinary, they being removed on high dry Ground, become more regular and handſome, and are more prolific of Flowers and Fruit. They uſually loſe their Leaves in Winter, unleſs it be very moderate.

The ſecond Sort is eſteemed the moſt beautiful Tree in *America*, where they uſually grow in moiſt ſwampy Woods, and often riſe to the Height of ſixty or ſeventy Feet; the Leaves are much larger than thoſe of our common Laurel, and are of a bright green Colour; the Flowers are very large, of a white Colour, and very fragrant. The Fruit is ſhaped like that of the former Sort, but are much larger, of a purple Colour when ripe, and emit the Seeds in like manner; ſo that in Autumn they make a moſt beautiful Appearance, and in *May* or *June*, when they are in Flower, the circumambient Air is perfumed with their Odour: The Leaves of theſe Trees, remaining green all the Winter, afford an agreeable Proſpect in that Seaſon. They are of quick Growth, and generally riſe with ſtrait Stems, which is a conſiderable Addition to their Beauty; and ſince they are hardy enough to reſiſt the Cold of our Climate in the open Air, I doubt not but we ſhall have the Pleaſure of ſeeing many of theſe Trees growing in the *Engliſh* Gardens in a few Years, where we may hope to have them annually produce their beautiful Flowers: for in the Garden of Sir *John Colleton* in *Devonſhire*, there is a Tree which has flowered ſeveral Years; and laſt Year, *i. e.* Anno 1737. there was a ſmall Tree in the Garden of Sir *Charles Wager* at *Parſons-Green* near *Fulham*, which produced Flowers.

The third Sort was diſcovered by Father *Plumier* in ſome of the *French* Settlements in *America*. The Fruit of this Sort (as it is repreſented in the Plate of Father *Plumier*'s *Nova Genera*) is very different from that of the ſecond Sort, and the Flowers appear much ſmaller; ſo that, if his Figure is true, it muſt be a different Sort from either of the former; but there are no Plants of his Kind in *England* as yet, ſo far as I can learn, tho' it is very probable, there are Trees enough of it to be met with in ſome Parts of *America*, which belong to the *Engliſh*, were they ſought for by ſkilful Perſons, who could diſtinguiſh them.

Theſe Plants are all of them propagated from Seeds, for they do not take Root well by Laying; nor do thoſe few Plants which have been obtained from Layers thrive, nor are they ever like to make handſome Plants: But as there are no Plants in *England* which are likely to produce Seeds in many Years, ſo there is no way to obtain them, but by procuring their Seeds from *America*. Theſe Seeds ſhould be ſown in Tubs of Earth ſo ſoon as they are ripe (for if they are kept out of the Ground any Time, they will not grow): Theſe Tubs ſhould be ſent over to *England* as ſoon as poſſible, and when they arrive, they ſhould be placed on a gentle Hot-bed, obſerving to ſhade them from the Sun, and often refreſh them with Water. In this Situation the Plants will appear above Ground in a Month or five Weeks; and if they are kept moiſt, and ſhaded from the Sun, will make conſiderable Progreſs. In *July* you ſhould begin to inure them to the open Air, but they ſhould not be expoſed to the Sun; for while they are young, the great Heat of the Sun is very injurious to them. In *October* the Tubs ſhould be placed under a Hot-bed Frame, where they may be covered in froſty Weather with the Glaſſes; but in mild Weather they ſhould be expoſed to the open Air; for if they are kept too cloſe, they will caſt their Leaves. In *March* following theſe Plants may be tranſplanted out of the Tubs; in doing of which you ſhould be careful to take them up with as much Earth to their Roots as poſſible; then place each Plant into a Pot, which ſhould be filled with light freſh Earth, giving them ſome Water to ſettle the Earth to their Roots; and place the Pots into a Frame again, where they ſhould be covered with the Glaſſes in cold Weather, or drying Winds; but they muſt be expoſed when the Weather is mild, and ſhould be frequently watered. In this Frame they may remain about a Month, after which they ſhould be placed abroad in a ſhady Situation, obſerving to water them often in dry Weather. Theſe Plants may remain two Years in the Pots, that they may be removed into Shelter in Winter, becauſe they are ſomewhat tender while young; but afterwards they may be turned out of the Pots into the full Ground, obſerving to plant them in a pretty moiſt Soil, where they will make conſiderable Progreſs in a few Years.

There have been ſeveral of theſe Plants deſtroyed, by the Over-care ſome Perſons have taken to cover them in Winter: for where this hath been done, the Plants uſually loſe their leading Bud, or die down to the Ground, ſo that it is by much the better Method, to plant them abroad in a well-ſheltered Situation, and to let them remain always uncovered: But when theſe Plants are planted abroad, it ſhould always be done in the Spring, that they may have Time to get good Roots in the Ground before Winter; and in very hard Froſt, if there is ſome Mulch laid on the Surface of the Ground about their Roots to prevent the Froſt from penetrating of the Ground, it will be of great Service in preſerving of the Plants; but this Mulch ſhould not remain long round the Trees, after the Froſt is gone off, leſt it ſhould injure the Bark of their Stems, by detaining the Moiſture about them.

MAHALEB. *Vide* Ceraſus.

MAJORANA, [ſo call'd, as tho' *Major ad Vitam*, Lat. becauſe it is ſaid to prolong Life, or becauſe it reſembles *Marum*; it is probably the *Marum* of the Ancients: it ſeems alſo to be the *Sampſuchus* of the Ancients; or it may be call'd *Ma-*

jorana and *Amarachus*, of α, Privative, and μαραίνω, *to wither*; becauſe this Plant does not eaſily rot nor wither: for it is a very dry one.] Marjoram.

The *Characters* are;

It is a verticillate Plant, whoſe Flower is compoſed of one Leaf: the Galea (or Creſt) is upright, roundiſh, and divided into two Parts: the Barba (or Beard) is cut into three Segments, ſo as to appear almoſt like a quinquifid Flower: the Flowers are collected into a ſhort, thick, round Head, and come out of a four-fold Order of Leaves, which are placed like Scales or Plates.

The *Species* are;

1. MAJORANA *vulgaris. C. B. P.* Common ſweet Marjoram.
2. MAJORANA *rotundifolia ſcutellata exotica. H. R. Par.* Round-leav'd exotick Marjoram, with a Leaf ſhaped like a Saucer.
3. MAJORANA *Cretica, origani folio villoſo, ſaturejæ odore, corymbis majoribus albis.* Hairy *Candia* Marjoram, with an Orange Leaf, a ſavoury Smell, and large, round, tufted white Heads.

The firſt of theſe Plants is an Annual, and muſt be ſown every Year: The Seeds of this are annually brought from *Marſeilles*, and other Places in the South of *France*, where it grows ſpontaneouſly; for it never ripens Seeds in this Country. The Seeds of this Plant ſhould be ſown the latter End of *March*, or the Beginning of *April*, upon a dry warm Spot of Ground; and when the Plants come up, they muſt be carefully clear'd from Weeds, (which, if permitted to grow, will ſoon over-run and deſtroy them) and in very dry Weather, the Beds ſhould be often water'd, which will greatly promote the Growth of them.

In *June* theſe Plants will be pretty ſtrong; at which Time you ſhould prepare ſome Beds of rich light Earth, into which you ſhould tranſplant ſuch of the Plants as require to be drawn out, where they come up too thick, at about four Inches Diſtance from each other, obſerving to water them, until they have taken Root; after which they will require no farther Care, but only to clear them from Weeds, and theſe Plants will grow ſtrong, and produce a greater Number of Heads (or Knots, as they are commonly call'd) than thoſe which remain'd in the Seed-beds unremoved; for which it is much preferr'd to it in the Markets, where it is call'd *Knotted Marjoram*, to diſtinguiſh it from that which is not ſo. Towards the latter End of *July* theſe Plants will flower, which is the proper Seaſon to pull them up for medicinal Uſe, when they ſhould be hung up in a ſhady Place to dry.

The ſecond Sort is a perennial Plant, which is preſerved by ſome curious Perſons in Pots, and placed in the Green-houſe in Winter. This Sort never produces Seeds with us, but is eaſily propagated by planting Cuttings or Slips, during any of the Summer Months, in a Bed of rich light Earth, obſerving to water and ſhade them until they have taken Root: At *Michaelmas* theſe Plants ſhould be taken up, and planted in Pots fill'd with rich light Earth; and when they are ſettled, they ſhould be removed into the Green-houſe, placing them near to the Windows, that they may have a good Share of free Air when the Weather is mild: You muſt often refreſh them with Water, but never give them too much at once, for that will rot them. With this Management the Plants may be preſerved freſh thro' the whole Year, and will be in a Condition to gather for Noſegays any Part of the Winter, and have as good a Scent as the *Sweet Marjoram*.

The third Sort was ſent into *England* by Sir *George Wheeler* from *Smyrna*, where it grows in great Plenty. This Plant riſes to the Height of two or three Feet, and becomes woody, but never produces any Seeds with us; tho' it is eaſily propagated by planting Slips or Cuttings in any of the Summer Months, after the Manner as was directed for the former Sort, and muſt be houſed in Winter, tho' it muſt not be kept too cloſe; for it only requires to be protected from great Rains and Froſt; but ſhould have as much free Air as poſſible in mild Weather, otherwiſe it is ſubject to draw, and grow very weak.

MALABAR-NUT. *Vide* Adhatoda.

MALA ÆTHIOPICA. *Vide* Lycoperſicon.

MALA ARMENIACA. *Vide* Armeniaca.

MALA COTONEA. *Vide* Cydonia.

MALA INSANA. *Vide* Melongena.

MALACOIDES, [Μαλακοειδὴς, of μαλακὴ, a *Mallow*, and εἶδος, the *Face*.]

The *Characters* are;

It hath the Flower and Appearance of a Mallow; *and hath a Fruit like that of a* Bramble, *but dry, which is compoſed of ſeveral Cells, collected into a ſort of little Head or Button, in which are contain'd many Kidney-ſhaped Seeds.*

There is but one *Species* of this Plant, at preſent, in the *Engliſh* Gardens, which is;

MALACOIDES *Betonicæ folio. Tourn.* Malacoides with a Betony Leaf.

This Plant is propagated by ſowing the Seeds in *March*, upon a Bed of freſh light Earth; and when the Plants are come up, they ſhould be tranſplanted into a warm dry Border, where they are to remain, (for this Plant does not care for being often removed) and ſome of them may be planted in Pots, that they may be ſhelter'd in Winter; for in very ſevere Froſts they are often deſtroy'd: The Summer following, they will produce their Flowers in *June*, and if the Seaſon be favourable, they will ſometimes ripen Seeds; but this does not often happen in our Country. There is no great Beauty in this Plant; but it is preſerved by ſuch as are curious in Variety.

MALLOW. *Vide* MALVA.

MALLOW-TREE. *Vide* Althæa.

MALPIGHIA, Barbadoes Cherry, *vulgo*.

The *Characters* are;

It hath a ſmall quinquifid Calyx, which conſiſts of one Leaf, having bifid Segments: the Flower conſiſts of five Leaves, which expand in form of a Roſe, *having ſeveral* Stamina *collected in form of a Tube: the Ovary in the Bottom of the Flower-cup becomes a globular fleſhy ſoft Fruit, in which is a ſingle Capſule, containing three ſtony winged Nuts.*

We have but one *Species* of this Plant in *England* at preſent; which is,

MALPIGHIA *mali punici facie. Plum. N. G.* Malpighia, with the Face of Pomegranate, *commonly call'd* in the *Weſt-Indies*, Barbadoes Cherry.

This Tree in the *Weſt-Indies* riſes to be fifteen or ſixteen Feet high, where it produces great Quantities of a pleaſant tart Fruit, for which Reaſon it is propagated in moſt of the Gardens of thoſe Countries; but in *Europe* it is only preſerved as a Curioſity by ſuch Perſons as delight in Variety. It is eaſily propagated by Seeds, (which ſhould be procured from the *Weſt-Indies*) and muſt be ſown upon a Hot-bed in *February*; when the Plants are come up, they muſt be tranſplanted each into a ſeparate ſmall Pot fill'd with freſh light Earth, and plunged into a Hot-bed of Tanners Bark, obſerving to ſhade them from the Violence of the Sun until they have taken Root, as alſo to water them from Time to Time as they may require; and when the Plants begin to acquire Strength, and the Seaſon is warm, they ſhould have a good Share of Air, eſpecially in the Middle of the Day) by raiſing the Glaſſes with a Stone or Brick: and if the Glaſſes are wet, it will be proper to turn them, that thoſe rancid Vapours may be dried up.

In *June* theſe Plants will have grown ſo as to fill the ſmall Pots with their Roots; at which Time they ſhould be ſhaken out, (preſerving the Earth intire about their Roots) and placed into larger Pots, which ſhould be fill'd up with the ſame light freſh Earth, and plunged again into the Hot-bed, obſerving to water them as before, as alſo to give them Plenty of Air in hot Weather; and in the Heat of the Day, when the Sun is very hot, it will be proper to ſhade the Glaſſes with Mats.

By thus managing them, they will grow to be eighteen Inches high before Winter, and have pretty ſtrong Stems, (provided they have had a ſufficient Quantity of Air;) but in *October*, when the Nights are cold, they ſhould be removed into the Stove, where they ſhould be plunged in the Tanners Bark with the *Papaws*, and other *Weſt-Indian* Plants, which Stove ſhould be kept up to *Anana's* Heat, as mark'd on Mr. *Fowler's Thermometers*, obſerving to water them in the Winter with Water that has ſtood twenty-four Hours in the Stove, ſo as to have acquired a Warmth proportional to the Air of the Houſe.

The Spring following they muſt be ſhifted into larger Pots, and again plunged into Tanners Bark, in which they ſhould conſtantly be kept, if you would have them vigorous; tho' they will live in a warm Stove without the Bark; but then they will not make near the Progreſs, nor appear ſo beautiful, as if kept in the Tanners Bark; and it is probable they may be brought to produce Fruit in Time, where the Stoves are good, and proper Care is taken of their Management.

MALT-DUST, is accounted a great Enricher of barren Ground: It contains in it a natural Heat and Sweetneſs, which gives the Earth whereon it is laid a proper Fermentation, as thoſe who live in Malting Countries have found by Experience.

Some are of Opinion, that there is not a greater Sweetener than *Malt-Duſt*, where the Grounds are natural Clay, and have contracted a Sourneſs and Auſterity, whether by reaſon of having lain long untill'd, and unexpoſed to the Air, or by reaſon of Water having ſtood long thereon.

MALVA, [ſo call'd of Μαλακίζω, or μαλάσσω, to *ſoften*, becauſe it is good to ſoften the Belly] Mallows.

The *Characters* are;

It hath a fibroſe Root; the Leaves are round, or angular; the Flower conſiſts of one Leaf, is of the expanded Bell-ſhaped Kind, and cut into five Segments almoſt to the Bottom: From the Center riſes a pyramidal Tube, for the moſt Part loaded with many ſmall Threads or Filaments: From the Center of the Flower-cup riſes the Pointal in the Tube, which becomes the Fruit, which is flat, round, and ſometimes pointed, wrapt up, for the moſt part, within the Flower-cup, and divided into ſeveral Cells ſo diſpoſed round the Axle, that each little Lodge appears moſt artificially jointed within the correſponding Striæ *or Channels: The Seed is, many Times, ſhaped like a Kidney.*

The *Species* are;

1. MALVA *vulgaris, flore majore, folio ſinuato. J. B.* Common Mallow, with a large Flower.
2. MALVA *ſylveſtris, folio ſinuato, flore albo. Sutherl.* Common Mallow, with a large white Flower.
3. MALVA *Sinenſis erecta, floſculis albis minimis.* China upright Mallow, with ſmall white Flowers.
4. MALVA *foliis criſpis. C. B. P.* The curl'd or furbeloe'd Mallow.
5. MALVA *folio vario. C. B. P.* Mallow with a variable Leaf.
6. MALVA *Orientalis erectior, flore magno ſuave-rubente. T. Cor.* Upright Oriental Mallow, with a large beautiful red Flower.

The firſt of theſe Plants is found wild in moſt Parts of *England*, but is rarely cultivated in Gardens. This is the Sort commonly uſed in Medicine, with which the Markets are ſupplied by the Herb-folks, who gather it in the Fields.

The ſecond Sort is a Variety of the firſt, from which it differs in the Colour of the Flower. This is preſerved by ſuch as are curious in preſerving great Varieties of Plants, but is rarely cultivated in other Gardens.

The third Sort was formerly ſent from *China* as a Pot-herb, and hath been cultivated in ſome curious Gardens in *England*; tho' it is not likely to obtain here as an eſculent Plant, ſince we have many others which are preferable to it for that Purpoſe. This is an annual Plant, which will propagate itſelf faſt enough, provided it be permitted to ſcatter its Seeds, when they ſeldom fail to grow, and are often very troubleſome when they have got Poſſeſſion of the Ground.

The fourth Sort is preſerv'd by ſome curious Perſons, for the Beauty of its Leaves, which are naturally furbeloe'd round their Edges. This is alſo an annual Plant, which will riſe four or five Feet high, and propagate itſelf in the ſame Manner as the former.

The fifth Sort is more rare than any of the former: It grows wild in *Spain* and *Italy*, from whence the Seeds were brought into *England*, and is preſerved by the Lovers of Variety, but there is no great Beauty in the Plant.

The ſixth Sort is alſo an annual Plant, which commonly grows upright to the Height of three or four Feet, and produces great Numbers of beautiful red Flowers; which renders it the beſt worth propagating in large Flower-Gardens, where being placed in the middle of large Borders, it makes a beautiful Appearance.

The Seeds of theſe Plants ſhould be ſown in *March* upon a Bed of freſh light Earth; and when they are come up four Inches high, they ſhould be tranſplanted where they are deſign'd to be continu'd, allowing 'em a large Diſtance, for if they are planted too cloſe, they do not appear ſo well: But they are beſt when intermix'd with other Flowers of the ſame Growth, where they afford an agreeable Variety.

Theſe Seeds may alſo be ſown in *Auguſt*; and the Plants will endure the greateſt Cold of our Climate, if placed on a dry Soil, and grow larger, and flower ſooner than thoſe ſown in the Spring: or if the Seeds are permitted to ſcatter, they will come up as the two former Sorts, and thrive equally as well.

There are ſeveral other Sorts of *Mallows*, ſome of which are Natives of this Country: But as they are Plants of no great Beauty or Uſe, ſo it would be ſuperfluous to mention them in this Place.

MALVA ARBOREA. *Vide* Althæa.

MALVA ROSEA; Roſe Mallow, or Hollyhock.

The *Characters* are;

It hath a larger and more expanded Flower than the Mallow; *which cloſely adheres to the Stalk, and, in many Species, the Flowers are double, where the Petals occupy the Place of the Style: It is in every reſpect larger than the Common* Mallow; *the Leaves are rougher, and the Plant grows almoſt ſhrubby.*

The *Species* are;

1. MALVA ROSEA *ſive hortenſis, flore albo. J. B.* Single White Hollyhock.
2. MALVA ROSEA *hortenſis, flore ſimplici rubro. H. Eyſt.* Single Red Hollyhock.
3. MALVA ROSEA, *folio rotundo, flore ex rubro nigricante. C. B. P.* Hollyhock, with a blackiſh-red Flower.
4. MALVA ROSEA, *folio ſubrotundo, flore ſimplici luteo. H. R. Par.* Hollyhock, with a ſingle Yellow Flower.
5. MALVA ROSEA, *folio ſubrotundo, flore pleno albo. C. B. P.* Double White Hollyhock.
6. MALVA ROSEA *hortenſis, flore pleno rubro. H. Eyſt.* Double Red Hollyhock.
7. MALVA ROSEA *multiplex, flore incarnato. H. Eyſt.* Hollyhock, with a Double Fleſh-colour'd Flower.
8. MALVA ROSEA *hortenſis, flore pleno, atro-rubente. H. Eyſt.* Double Hollyhock, with a Dark-red Flower.
9. MALVA ROSEA, *folio ſubrotundo, flore pleno puniceo. C. B. P.* Hollyhock, with a double ſcarlet Flower.
10. MALVA ROSEA, *folio ſubrotundo, flore pleno ſubluteo. H. R. Par.* Hollyhock, with a Double Yellowiſh Flower.

There are ſome other Varieties of theſe Plants, which differ in the Colour of their Flowers: But as they are near to one or other of theſe Colours, and are either paler or deeper (none of the Sorts yet known being intirely different in Colour from thoſe here mention'd); ſo it would be needleſs in this Place to inſert all their minute Diſtinctions, eſpecially as they are ſeminal Variations, and ſeldom produce the ſame exact Colours again from Seeds.

Theſe Plants are all propagated from Seeds, which ſhould be ſown upon a Bed of freſh Earth, in *March*; and when the Plants are come up pretty ſtrong, they muſt be tranſplanted out into Nurſery-beds at about eight Inches Diſtance from each other, obſerving to water them until they have taken Root: After which they will require no farther Care until the *Michaelmas* following, but only to keep them clear from Weeds; at which Time they ſhould be tranſplanted into Rows two Feet aſunder, and a Foot Diſtance in the Rows; in which Place they may continue until they flower, when you ſhould mark all thoſe with Double Flowers, which have good Colours, with Sticks, that they may be tranſplanted into the Borders of large Gardens at *Michaelmas*, where they will remain four or five Years, and produce their Flowers very ſtrong: But when the Roots are much older, they begin to decay, and do not produce their Stems ſo ſtrong, nor are their Flowers ſo large; wherefore there ſhould always be a Supply of young Plants rais'd from Seeds every third or fourth Year, in order to have the Flowers in Perfection: But it is the better Way to change the Seeds every three or four Years, with ſome Perſon of Integrity who lives at a conſiderable Diſtance, and is exact to ſave Seeds from none but Double Flowers, and ſuch as are well-colour'd, by which means you may preſerve the Sorts well from degenerating: But if you conſtantly ſave the Seeds in the ſame Place, they will in a few Years become little worth.

The ſeveral Varieties of theſe Plants, when carefully intermix'd in large Wilderneſs Borders, or Avenues, afford an agreeable Proſpect during their Seaſon of flowering (which is commonly in *July*); but as they grow to a conſiderable Height, and ſpread pretty wide, ſo they take up too much Room, and appear unſightly in ſmall Flower-Gardens: They ſhould alſo be ſupported with Stakes, otherwiſe they are ſubject to be broken down by ſtrong Winds.

When the Stalks of theſe Plants begin to decay, they ſhould be cut down pretty cloſe to the Ground, to encourage them to ſhoot out freſh Heads for the ſucceeding Year, otherwiſe they ſometimes rot and deſtroy the Roots.

MALUS; The Apple-Tree.

The *Characters* are;

The Tree groweth very large; the Branches ſpread (and are more depreſſed than thoſe of the Pear Tree); the Flower conſiſts of five Leaves, which expand in form of a Roſe; the Fruit is hollowed about the Footſtalk, is for the moſt part roundiſh, and umbilicated at the Top, is fleſhy, and divided into five Cells or Partitions, in each of which is lodg'd one oblong Seed.

The *Species* are;

1. MALUS *ſylveſtris, acido fructu albo. Tourn.* The Crab Tree.
2. MALUS *ſylveſtris, foliis ex albo eleganter variegatis. Cat. Plant. Hort.* The Crab Tree, with ſtrip'd Leaves.
3. MALUS *ſylveſtris Virginiana, floribus odoratis. Cat. Plant. Hort. Virginian* Crab Tree, with ſweet Flowers.
4. MALUS *fructifera, flore fugaci. H. R. Par.* The Fig Apple.
5. MALUS *pumila, quæ potius frutex, quam arbor, fructu rubente & candido. C. B. P.* The Paradiſe Apple.
6. MALUS *ſativa, foliis eleganter variegatis. Cat. Plant. Hort.* Apple Tree, with ſtrip'd Leaves.

The ſeveral Sorts of *Apples* which are at preſent eſteem'd for their Fruit in the curious Gardens near *London*, may be ſeen under the Article of *Apple*, where a particular Account of their Planting, Pruning, *&c.* is fully laid down; to which I refer the Reader; and in this Place ſhall only take notice of the above-mention'd Sorts, which are only preſerv'd as Curioſities, or for Stocks to graft the more generous Kinds of Fruit upon; the *Crab Tree* is generally preferr'd to moſt other Sorts for this Purpoſe, it being the moſt durable of them, and not ſo liable to canker as thoſe which are produc'd from Kernels of better *Apples*: But theſe ſhould be obtain'd from Kernels, and not Suckers taken from the Woods, which are generally ill-rooted, and ſeldom make a handſome Stock; nor will they ſo readily join with the Cyon, for which Reaſon they ſhould not be planted.

The *Paradiſe Apple* hath, of late Years, greatly obtained for Stocks to graft or bud upon; but theſe are not of long Duration; nor will the Trees grafted upon them ever grow to any Size, unleſs they are planted ſo low as that the Cyon may ſtrike Root into the Ground, when it will be equal to no Stock, for the Graft will draw its Nouriſhment from the Ground; ſo that it is only by way of Curioſity, or for very ſmall Gardens, that theſe Stocks are proper, ſince there can never be expected any conſiderable Quantity of Fruit from ſuch Trees.

The *Virginian Crab Tree* with ſweet Flowers, is preſerv'd by ſuch Perſons as are curious in collecting great Variety of Trees: It may be propagated by Budding or Grafting it upon the common *Crab* or *Apple Tree*; but it is ſomewhat tender while young, wherefore it ſhould be planted in a warm Situation, otherwiſe it will be ſubject to ſuffer by an extreme hard Winter. The Flowers of this Tree are ſaid to be exceeding ſweet in *Virginia*, where it grows in the Woods in great Plenty; but I could not obſerve much Scent in ſome of them which flower'd in *England* the laſt Year; ſo that I am in doubt whether the Sort at preſent in the Gardens is the very ſame with that of *Virginia*, or perhaps it may have degenerated by ſowing the Seeds, which, I ſuppoſe, is the Way it was firſt obtain'd in *England*.

The *Fig Apple* is ſuppos'd, by many Perſons, to be produc'd without a previous Flower. But this Opinion is rejected by ſome curious Obſervers, who affirm, there is a ſmall Flower precedes the Fruit, which is very fugacious, ſeldom continuing above a Day or two. Now, which of theſe Opinions is the right, I have not, as yet, had an Opportunity to determine, not having a Tree in my own Poſſeſſion which is arriv'd at Maturity to produce Fruit; tho' it might reaſonably be expected, that ſuch who have had Trees of this Kind ſeveral Years, might have determin'd this Point long ere this Time.

I remember an Account of a large Tree of this Kind, mention'd in a Letter from *New-England*, written by *Paul Dudley*, Eſq; to the *Royal Society*, and publiſh'd in the *Philoſophical Tranſactions*, Numb. 385. which was exceeding large, and produc'd great Quantities of Fruit, without any previous Flowers; but it grew at ſome Diſtance from his Habitation, and he having no other Opportunity to obſerve it ſtrictly himſelf, but by viſiting the Place two or three Times about the Seaſon of flowering, and not being appriz'd of the ſudden Decay of the Flowers, they might eaſily be ſuppos'd to have appear'd, and dropt off between the Times of his viſiting the Place.

The two Sorts with ſtriped Leaves are preſerv'd by ſuch as are curious in collecting ſuch Varieties: Theſe may be propagated by grafting or budding them upon the common *Apple* or *Crab Tree*; but they ſhould not be planted in a very rich Soil, which would cauſe them to grow very free, whereby their Leaves would become entirely green again.

MALUS ARMENIACA. *Vide* Armeniaca.

MALUS AURANTIA. *Vide* Aurantia.

MALUS LIMONIA. *Vide* Limonia.

MALUS MEDICA. *Vide* Citreum.

MALUS PERSICA. *Vide* Perſica.

MALUS PUNICA. *Vide* Punica.

MAMEI, The Mammee-Tree.

The *Characters* are;

It hath a roſaceous Flower, which conſiſts of ſeveral Leaves placed in a circular Order, from whoſe Cup ariſes the Pointal, which afterward becomes an almoſt ſpherical fleſhy Fruit, containing two or three Seeds incloſed in hard rough Shells.

There is but one *Species* of this Tree known; *viz.*

MAMEI *magno fructu, perſicæ ſapore. Plum. Nov. Gen.* 44. The Mammee, with a large Fruit taſting like a Peach.

This Tree, in the *Weſt-Indies*, grows to the Height of ſixty or ſeventy Feet; the Leaves are large and ſtiff, and continue green all the Year; the Fruit is as large as a Man's Fiſt; when ripe, is of a yellowiſh green Colour, and is very grateful to the Taſte. It grows in great Plenty in the *Spaniſh Weſt-Indies*, where the Fruit is generally ſold in their Markets, and is eſteemed one of the beſt Fruits of the Country. It alſo grows on the Hills in *Jamaica*, and has been tranſplanted into moſt of the *Caribbee* Iſlands, where it thrives exceeding well.

In *England* there are ſome few of theſe Plants, which are preſerved with great Care by ſuch as are curious in cultivating exotic Plants; but there are none of any conſiderable Size; ſo that we cannot expect to ſee either Fruit or Flowers for ſome Years. Theſe Plants may be propagated by planting the Stones which are often brought from the *Weſt-Indies*; (but theſe Stones ſhould be very freſh, otherwiſe they will not grow) into Pots filled with light freſh Earth, and plunged into a Hot-bed of Tanners-bark, obſerving to water the Earth, whenever it appears dry. In about a Month the Plants will begin to appear above Ground; after which they muſt be frequently refreſhed with Water; and in hot Weather the Glaſſes of the Hot-bed ſhould be raiſed, to let in freſh Air. In two Months the Roots of the Plants will have filled the Pots, when you ſhould provide ſome Pots of a little larger Size, into which you ſhould tranſplant the Plants, being careful to preſerve as much Earth to their Roots as poſſible; then you ſhould fill up the Pots with freſh light Earth, and plunge them into the Bark-bed again, obſerving to water and ſhade them, until they have taken Root; after which they ſhould be conſtantly refreſhed with Water, (as you ſhall find they want it) and muſt have Air in hot Weather. In this Bed they may remain till *Michaelmas*, when they muſt be removed into the Bark-ſtove, where they muſt be conſtantly kept, obſerving to refreſh them with Water frequently, as alſo to clean their Leaves from the Filth they are apt to contract in the Stove; and the Spring following they ſhould be ſhifted into freſh Earth, and, if they require it, into larger Pots; and the Bark-bed muſt be freſh ſtirred, and ſome new Tan mixed therewith, to renew the Heat. This ſtirring of the Tan ſhould be repeated as often as there may be a Neceſſity for it, which is at leaſt three Times a Year; and when it begins to rot, ſome new Tan muſt be added to renew the Heat. In all other reſpects this Tree may be treated after the Manner directed for the Coffee-Tree.

MANCANILLA, The Manchineel-Tree.

The *Characters* are;

It hath Male Flowers, (or Katkins) which are produced at remote Diſtances from the Embryo's on the ſame Tree; the Em-

bryo becomes a round fleſhy Fruit, in which is contained a rough woody Nut, incloſing four or five flat Seeds.

The *Species* are;

1. MANCANILLA *pyri facie. Plum. Nov. Gen.* 50. The Manchineel with the Face of a Pear-Tree.
2. MANCANILLA *aquifolii foliis. Plum. Nov. Gen.* 50. The Manchineel with Leaves like Holly.
3. MANCANILLA *lauri foliis oblongis. Plum. Nov. Gen.* 50. The Manchineel with oblong laurel Leaves.

The Manchineel is a Native of the *Weſt-Indies*, where it grows on low ſandy Land, or near Gullies, where Water runs. The three Sorts here mentioned are diſtinguiſhed by Botaniſts, but I believe their Difference is not remarked by the Natives. They grow to be very large Trees, equal to the Size of an Oak, and are much eſteemed for their Wood, which is ſawn out into Planks, and brought over to *England*: It is uſed for Cabinets, Book-Caſes, *&c.* and will poliſh very well, is of a beautiful Grain, and will laſt a long Time. In cutting down of theſe Trees, they are very careful to burn out the Juice of the Bark, before they begin; otherwiſe the Perſons are in Danger of loſing their Eyes by ſome of the Sap getting into them, which is of a milky Colour, and ſo very cauſtic, that it will raiſe Bliſters on the Skin, and burn Holes in Linen. The Fruit of this Tree, when ripe, is of the Colour and Size of a Golden Pippen; for which many of the *Europeans* have taken it, and ſome by eating thereof loſt their Lives, and others have greatly ſuffered; the Fleſh is not much thicker than a Crown-piece, and not very diſagreeable to the Taſte, but will corrode the Mouth and Throat. The Leaves of theſe Trees alſo abound with a milky Juice, which is of the ſame Nature; ſo that it is dangerous being under their Drip: The Cattle in *America* never ſhelter themſelves under them, nor will any Vegetable ſcarcely grow under their Shade; yet the Goats eat this Fruit, without any manifeſt Injury to themſelves, or their Milk, which is not altered by this Food.

In *England* there are ſome of theſe Trees preſerved by Perſons who are curious in propagating exotic Plants. They may be raiſed from Seeds, by putting the whole Apple or Nut into a Pot of freſh Earth, and then plunge it into a Hot-bed of Tanners-bark, obſerving to refreſh the Earth often with Water. From one of theſe Nuts will ariſe four or five Plants, which, when grown about three Inches high, may be ſeparated, and placed each into a ſmall Pot filled with light rich Earth, and plunged again into the Hot-bed, obſerving to water and ſhade them, until they have taken Root; after which they muſt be managed as was before directed for the *Mammee*, to which I refer the Reader to avoid Repetition; in ſhifting of theſe Plants from one Pot into another, great Care ſhould be had, not to break their Leaves; for then they will bleed greatly, and thereby the Plants will be weakened; and it is very dangerous to let any of the Juice fall on any tender Part of the Body, for it will raiſe a Bliſter: And if it fall on Cloth, it will make Holes therein, as bad as if *Aqua fortis* were dropp'd on it.

MANDRAGORA: Mandrake.

The *Characters* are;

The Flower conſiſts of one Leaf, in the Shape of a Bell, and is divided at the Top into ſeveral Parts; the Pointal afterwards becomes a globular ſoft Fruit, in which are contain'd many Kidney-ſhap'd Seeds.

The *Species* are;

1. MANDRAGORA *fructu rotundo. C. B. P.* Common Mandrake, with a round Fruit.
2. MANDRAGORA *flore ſubcœruleo purpuraſcente. C. B. P.* Mandrake, with a purpliſh blue Flower.

Theſe Plants are propagated by Seeds, which ſhould be ſown upon a Bed of light Earth ſoon after they are ripe; for, if they are kept until the Spring, they ſeldom ſucceed well; and, in the Spring, the Plants will appear above-ground, when they ſhould be carefully clear'd from Weeds; and, in very dry Weather, they muſt be refreſh'd with Water, which will greatly promote their Growth: In this Bed they ſhould remain till the latter End of *Auguſt* (obſerving always to keep them clear from Weeds); at which Time they ſhould be taken up very carefully, and tranſplanted into the Places where they are to remain, which ſhould be a light deep Soil, for their Roots do always run downward very deep; ſo that, if the Soil be wet, they are often rotted in Winter; and, if it be too near the Gravel or Chalk, they ſeldom thrive well; but, if the Soil be good, and they are not diſturb'd, the Plants will grow to a large Size in a few Years, and will produce great Quantities of Flowers and Fruit, and they will abide a great many Years.

I have been inform'd, by ſome Perſons of Credit, that one of theſe Roots will remain ſound above fifty Years, and be as vigorous as a young Plant; but they ſhould never be remov'd after their Roots have arriv'd to any conſiderable Size, which would break their lower Fibres, and ſo ſtunt the Plants, as that they will not recover their former Strength in two or three Years.

As to the feigned Reſemblance of a Human Form, which the Roots of this Plant are ſaid to carry, 'tis all Impoſture, owing to the Cunning of Quacks and Mountebanks, who deceive the Populace and the Ignorant with fictitious Images ſhaped from the freſh Roots of *Briony* and other Plants: And what is reported as to the Manner of rooting up this Plant, by tying a Dog thereto, to prevent the certain Death of the Perſon who ſhould dare to attempt it, and the Groans it emits upon the Force offer'd, *&c.* 'tis all a fulſome Fable; for I have taken up ſeveral large Roots of this Plant, ſome of which have been tranſplanted into other Places, but could never obſerve any particular Difference in this from any other deep-rooting Plant.

MANIHOT, Caſſavi or Caſſada.

The *Characters* are;

It hath a ſhort ſpreading bell-ſhaped Flower, conſiſting of one Leaf, which is cut into ſeveral Parts, whoſe Pointal afterwards becomes a roundiſh Fruit, compoſed of three Cells, which are joined together, in each of which is contained one oblong Seed. To theſe Notes ſhould be added; Male Flowers, which have no Pointal, growing round the Female, which fall off, and are never fruitful.

The *Species* are;

1. MANIHOT *Theveti juca & Caſſavi. J. B. Inſt. R. H.* The common Caſſavi or Caſſada.
2. MANIHOT *ſpinoſiſſima, folio vitigineo. Plum. Cat.* The moſt prickly Caſſavi, with a chaſte-tree Leaf.
3. MANIHOT *arboreſcens minus ſpinoſa, floribus albis umbellatis, foliis aconiti urentibus. Houſt.* Tree-like leſs prickly Caſſavi, with white Flowers growing in Umbels, and a ſtinging Wolfsbane Leaf.
4. MANIHOT *fruteſcens non ſpinoſa, foliis glabris & minus laciniatis. Houſt.* Shrubby Caſſavi without Prickles, and ſmooth Leaves, which are leſs divided.
5. MANIHOT *ulmi folio ampliore. Plum. Cat.* Caſſavi with an ample Elm-leaf.
6. MAHINOT *ulmi folio anguſtiore. Plum. Cat.* Caſſavi with a narrow Elm-leaf.

The firſt Sort is cultivated in all the warm Parts of *America*, where the Root is ground to Flour, after being diveſted of its Juice; and then is made into Cakes, which are uſed for Bread. Of this there are two Sorts, which are not diſtinguiſhed by the Botaniſts, one of which, (*viz.*) the moſt common, hath purpliſh Stalks, and the Veins of the Leaves are alſo of a purpliſh Colour; but the Stalks of the other are green, and the Leaves are of a lighter green Colour. The laſt of theſe Sorts is not venomous, even while the Roots are freſh, and full of Juice; for the Negroes frequently dig up the Roots, and after roaſting of them, they eat them in the ſame Manner as Potatoes, without any ill Effects. This Sort is known by the *Spaniards*, who call it *Camanioc*; but this being more light and ſpongy than the common Sort, and requiring a longer Time to grow to Maturity, ſo it is planted by few People in *America*.

The *Caſſada* is propagated by Cuttings, which the Inhabitants of *America* plant, at their rainy Seaſons; theſe Cuttings are taken from thoſe Plants, whoſe Roots are grown to Maturity, for Uſe. The Cuttings are generally about fifteen or ſixteen Inches in Length, and are planted a Foot or fourteen Inches deep in the Ground, leaving about two or three Inches of the Cutting above the Surface. The Land in which this is planted, muſt be well wrought, and cleanſed from the Roots of noxious Weeds; then there ſhould be a Trench opened croſs the Ground about a Foot deep, in which the Cuttings ſhould be placed at about a Foot Diſtance from each other, leaving a ſmall Part of each Cutting above the Surface: Then the Earth ſhould be filled into the Trench again, and gently preſſed with the Feet about each Cutting, to prevent the Sun and Air from penetrating of the Ground, which would dry the Cuttings too much, and ſo prevent their taking Root. Theſe Trenches ſhould be made about three Feet aſunder, that there may be Room to hough between the Rows to deſtroy the Weeds, which, if permitted to grow, will ſoon overbear the Plants, and deſtroy them. The Cuttings ſhould not be planted immediately after they are taken from the old Plants, but ſhould be laid to dry in a ſhady Place for two Days; for as they abound with a milky Juice, ſo, if the Part where they are cut, be not healed over, they will be ſubject to rot, as is the Caſe with moſt milky Plants.

When the Cuttings have taken Root, they require no farther Care, but to keep them clear from Weeds; and in about eight or nine Months Time, the Roots will have grown to Maturity, which in good Ground will be as large as the Calf of a Man's Leg, but commonly as large as good *Parſnips*, if the Ground be tolerably good. Then the Ground muſt be opened about each Plant to take up the Roots intire, and pare off their Skins; then they throw them into a Tub of Water, and waſh them well; after which they raſp them on a coarſe Raſp, to reduce them to a rough Flour like Saw-duſt; then they preſs out all the Juice with a Preſs, and afterwards it is fit for Uſe.

In *Europe* theſe Plants are preſerved by many Perſons, who are curious in collecting of rare Plants; but they will not thrive, unleſs they are kept in Stoves; for they are all of them very tender Plants. The ſecond Sort is only propagated by Seeds, which muſt be procured from the Places of its natural Growth, for it never produces good Seeds in this Country.

The Seeds of this Sort were ſent into *England* by the late Dr. *William Houſtoun*, who gathered them on the Sands near *Vera Cruz* in the *Spaniſh Weſt-Indies*, where it grows in great Plenty; it was alſo found at *Campechy* by Mr. *Robert Millar*, Surgeon. This Kind ſeldom riſes above eighteen Inches or two Feet high, and the Stalks, Leaves, and every Part of the Plant, is cloſely beſet with ſtrong Prickles, ſo that it is difficult to touch them, without receiving an Injury from the Spines. At the Top of the Shoots, there are ſome white Flowers, which are produced in an Umbel, ſome of which are *Male*, having many Stamina or Threads in each; but the *Female* Flowers reſt on the Embryos, which afterward become the Fruit.

The third Sort was alſo diſcovered by the late Dr. *William Houſtoun* near *La Vera Cruz*: This grows to the Height of twelve or fourteen Feet; the Trunk of this becomes woody, and divides at the Top into the Branches, which are beſet with Leaves, in Shape like thoſe of *Wolfsbane*; theſe are armed with ſmall Spines, which ſting like thoſe of the Nettle. The Flowers of this Kind are white, and grow in an Umbel on the Top of the Branches, and are produced throughout the whole Year. This Sort may be propagated by Cuttings in the ſame Manner as the firſt.

The fourth Sort is ſomewhat like the wholeſome Kind, but is not found in any of our Settlements: This was found in the *Iſland of Cuba*, by the late Dr. *Houſtoun*. All theſe Sorts have large tuberoſe Roots, which abide ſome Years, ſo may be preſerved by the Curious. When the Kinds are obtained from Abroad, they muſt be planted in Pots filled with freſh light Earth, which is not over-rich, and they ſhould be plunged in the Bark-bed in the Stove; where, during the Summer-ſeaſon, they ſhould have a large Share of freſh Air admitted to them, by opening of the Glaſſes in warm Weather, and they muſt be frequently refreſhed with Water; but in Winter they muſt be kept very warm, and ſhould be water'd more ſparingly, eſpecially if the Plants die down to the Root, which the ſecond Sort is very apt to do in Winter in this Country; at which Time Moiſture will rot the Roots, while they are in an unactive State.

When the Seeds of theſe Plants are procured from Abroad, they ſhould be ſown in Pots filled with freſh light Earth, and plunged into a Hot-bed of Tanners-bark, obſerving frequently to water the Earth, in order to promote the Vegetation of the Seeds; and when the Plants are come up two Inches high, they ſhould be tranſplanted each into a ſeparate Pot filled with freſh light Earth, and plunged into the Hot-bed again, being careful to ſhade them from the Sun, until they have taken freſh Root: after which Time they ſhould have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and they muſt be frequently refreſhed with Water. In this Hot-bed the Plants may remain during the Summer-ſeaſon, but at *Michaelmas* they muſt be removed into the Stove, and treated after the Manner as was before directed.

The Seeds of theſe Plants very often prove abortive, having a fair outer Covering; but when broken have no Germ within, ſo that very few of them grow; therefore it is proper to put them into Water, and take only ſuch for ſowing, as ſink to the Bottom of the Veſſel; for all thoſe which ſwim on the Surface of the Water, are bad Seeds.

MANURE.

There are many different Kinds of Manure, which are now commonly uſed in different Parts of *England*, for enriching of the ſeveral Soils: but theſe having been treated of under the Head of Dung, &c. and being pretty generally known, I ſhall not repeat them in this Place; but proceed to take Notice of ſome other Kinds of Manure, which are at preſent neglected by moſt People, tho' they might be uſed with equal Succeſs on many Lands, as moſt of thoſe now commonly in Uſe.

Oak-bark, after the Tanners have uſed it for Tanning of Leather, when laid in a Heap, and rotted, is an excellent Manure, eſpecially for ſtiff cold Land, in which one Load of this Manure will improve the Ground more, and laſt longer, than two Loads of the richeſt Dungs; and yet it is very common to ſee large Heaps of this remaining in the Tanners Yards for Years, in ſeveral Parts of *England*, where Manure of other Kinds is very ſcarce. Of late Years this Tan has been greatly uſed for Hot-beds in ſeveral Parts of *England*, and is found to exceed Horſe-dung greatly for that Purpoſe, the Fermentation being moderate, and of long Continuance; ſo that a Bed of Tan, when rightly made, will continue in a moderate Temperature of Heat for five or ſix Months; and when the Heat begins to decay, if it be ſtirred up with a Dung-fork, and ſome freſh Tan added to it, the Heat will renew again, and laſt for ſome Months; ſo that theſe Beds are by far the moſt kindly for exotic Plants; and whatever Plants are plunged into theſe Beds, if they are permitted to root thro' the Bottom of the Pots, and ſtrike into the Tan, they will thrive more in one Month, than they did in four Months, while they were confined to the Pots. I have frequently obſerved many Kinds of Plants, which have rooted thro' the Pot into the Tan, and have ſent forth Roots upward of twelve Feet each way, in leſs than three Months, and the Plants have advanced in Proportion, which is a plain Indication, that Plants are greatly nouriſhed by the rotten Tan. After the Tan hath been uſed for a Hot-bed, I have ſpread it on the Ground for Manure, and have found it has greatly enriched the Ground; but it is much better for cold ſtrong Land, than for light hot Ground, becauſe it is of a warm Nature, and will looſen and ſeparate the Earth; ſo that where this Manure hath been uſed three or four times, it hath made the Land very looſe, which before was ſtrong, and not eaſy to be wrought. When this Manure is laid on Graſs, it ſhould be done ſoon after *Michaelmas*, that the Winter Rains may waſh it into the Ground; for if it is laid on in the Spring, it will burn the Graſs, and inſtead of improving it, will greatly injure it for that Seaſon. Where it is uſed for Corn-land, it ſhould be ſpread on the Surface, before the laſt Ploughing, that it may be turned down for the Fibres of the Corn to reach it in the Spring; for if it lies too near the Surface, it will forward the Growth of the Corn in Winter; but in the Spring, when the Nouriſhment is chiefly wanted to encourage the Stems, it will be nearly conſumed, and the Corn will receive little Advantage from it. But it is not proper to have this Manure lie too near the Plants; for when this has happened, I have frequently obſerved it prejudicial to moſt Plants, but eſpecially to *bulbous* and *tuberoſe* rooted Flowers, which are very ſubject to rot, where it lies near their Roots; yet when it is buried juſt deep enough for the Fibres of their Roots to reach it in the Spring, the Flowers have been exceedingly improved by it. And in ſome Places, where this Manure hath been uſed in Kitchen-Gardens, it hath greatly improved the Vegetables; ſo that it is to be wondered, that this ſhould not be employ'd on the Land in every Country where it can be obtained.

Rotten Vegetables of moſt Sorts do alſo greatly enrich Land, ſo that where other Manure is ſcarce, theſe may be uſed with great Succeſs. The Weeds of Ponds, Lakes or Ditches, being dragged out before they ſeed, and laid in Heaps to rot, will make excellent Manure, as will moſt other Sorts of Weeds; but where-ever any of theſe are employed, they ſhould be cut down as ſoon as they begin to flower; for if they are ſuffered to ſtand until their Seeds are ripe, the Land will be ſtored with Weeds, which cannot be deſtroyed in two or three Years; nay, ſome Kinds of Weeds, if they are permitted to ſtand ſo long as to form their Seed, they will perfect them after they are cut down, ſo may be equally prejudicial to the Land: therefore the ſureſt Method is to cut them down juſt as they begin to flower, at which Time moſt Sorts of Vegetables are in their greateſt Vigour, being then ſtronger, and fuller of Juice, than when their Seeds are farther advanced; ſo that at that Time they abound moſt with Salts, and therefore are more proper for the intended Purpoſe. In rotting of theſe Vegetables, it will be proper to mix ſome freſh Earth, Mud or any other ſuch-like Subſtance, with them, to prevent their taking Fire in their Fermentation, which they are very ſubject to, where they are laid in large Heaps without any other Mixture to prevent it; and it will be proper to cover the Heaps over with Earth, Mud or Dung, to detain the Salts, otherwiſe many of the finer Particles will evaporate in fermenting.

When theſe Vegetables are thoroughly rotted, they will form a ſolid Maſs, which will cut like Butter, and be very full of Oil, which will greatly enrich Land.

In ſuch Places where there are neither Ponds, Lakes or Ditches, to ſupply theſe Weeds, and the Situation being far from the Sea, (from whence alſo may be obtained many Sorts of Weeds for this Purpoſe) there may be many Sorts of Vegetables ſown, in order to plough them into the Grounds, when they are full-grown, to enrich the Land: at preſent thoſe chiefly uſed for this Purpoſe are ***Buck-wheat***, ***Vetches*** and *Spurrey*. And in ſome Countries abroad, they commonly ſow *Lupines* upon ſuch Land as they want to improve; and when they are full-grown, they mow them down, and plough them into the Ground, which they eſteem to be a good Manure. This is chiefly uſed in the South of *France* and in *Italy*, where ſome of the Sorts of *Lupines* grow naturally; but theſe are not proper for this Climate, becauſe if the Seaſon ſhould prove cold or wet, after the *Lupines* are ſown, they will rot in the Ground; ſo that it is very hazardous ſowing of them in this Country; and there being many other Sorts of Plants, which are hardy, and grow to a much larger Size with us than *Lupines*, ſhould be preferred to them for this Purpoſe. I have known ſome Land ſown pretty thick with *Horſe-beans*, which have been mow'd down when they were in Bloſſom, and ploughed in for a Crop of Wheat, and it hath largely repayed the Owner. Almoſt any of the pulſe Kind which grow large, are very proper to be ſown for this Purpoſe; and, next to theſe, may be ſown *Muſtard*, *Cole-ſeed*, or any of theſe large growing Plants, which, if cut before they form their Seeds, and ploughed in, will greatly enrich the Ground.

The Refuſe of Kitchen-Gardens, when laid in Heaps and rotted, will alſo afford a good Sort of Manure for Corn-land; but as this is not to be obtained in any Quantity, excepting near great Cities, ſo in ſuch Places Dung being alſo to be had pretty reaſonable, the other will not be ſo much ſought after.

I have lately been informed of another Improvement, which may be of great Uſe in ſeveral Parts of the Kingdom; which is the mowing down of *Fern*, while it is green and tender, and laying it in Heaps to rot, which will make an excellent Manure for Land; and as this is a moſt troubleſome Plant in many Parts of *England*, ſo by frequently mowing of it, it may be deſtroyed; and when rotted, a good Quantity of Manure may be obtained, which will more than defray the Charges of cutting it down. In ſome Places, where no Tan or Horſe-dung can be obtained, they have cut down Fern, and chopped it pretty ſmall, and laid it in a Heap to ferment; then have uſed it for Hot-beds, for which Purpoſe it has anſwered extremely well. This firſt Perſon who informed me of this, was Mr. *Samuel Brewer*, a very curious Perſon in Gardening, who made ſeveral Hot-beds of *Fern*, which, he ſays, continued their Heat for many Months; ſo that he prefers it to Tan, or any ſort of Dung, where a moderate laſting Heat is required.

There are many other Kinds of Weeds, which infeſt the Land in many Parts of *England*, which, if cut down at a proper Time, and laid to rot, might be uſed to great Advantage for Manuring of Land; and hereby the Weeds would in time be deſtroyed, and the Manure would more than pay the Expence of doing it; but few Perſons who are employed in Huſbandry, care to go out of their old beaten Road to try Experiments, even where they are attended with little Expence, and nothing hazarded; otherwiſe there is great Room to make many Improvements of this Kind, eſpecially in Countries where Dung or other common Manure is very ſcarce, in which Places if ſome Experiments were properly made of rotting whatever Vegetables could be procured in the Neighbourhood, a great Improvement might be made of the Land.

The Aſhes of all Kinds of Vegetables are alſo an excellent Manure for Land, ſo that where the Ground is over-run with *Buſhes*, *Brambles*, &c. which are woody, if they are grubbed up in Summer, and ſpread abroad to dry for a little Time, then gently conſumed to Aſhes, and theſe ſpread on the Land, it will greatly improve it. The Method for doing this is already explained under the Article of Land.

Rotten Wood, and Saw-duſt when rotted, is a very good Manure for ſtrong Land, becauſe it looſens the Parts of the Earth, and renders it light.

Bones, Horns, and other Parts of Animals, do alſo enrich Land greatly, as do decayed Fiſh, ſo that in ſome Places where theſe can be eaſily obtained, a great Improvement may be made of them.

Sea-ſand and Shells are in ſeveral Parts of ***England*** uſed to great Advantage, eſpecially in ***Devonſhire***, where they are at the Expence of fetching the Sand and Shells on Horſes Backs, twelve or fourteen Miles. The Land on which they lay this Manure, is a ſtrong Loam, inclining to Clay; ſo that this ſeparates the Parts and the Salts which are contained in the Manure, and is a very great Improvement of their Land. Coral and ſuch Kinds of ſtony Plants which grow on the Rocks, are filled with Salts which are very beneficial to Land; but as theſe Bodies are hard, ſo the Improvement is not the firſt or ſecond Year after they are laid on the Ground; becauſe they require Time to pulveriſe them before their Salts can mix with the Earth to impregnate it. Therefore Dreſſings of this Kind are ſeldom uſed by Tenants, who want to reap the Fruit of their Labour as ſoon as poſſible. But theſe Manures are much better for cold ſtrong Land, than for that which is light and ſandy. In ſome Countries, at a great Diſtance from the Sea, have been diſcovered great Quantities of Foſſil Shells, which have been dug out of the Earth, and uſed as Manure, which have improved the Ground; but theſe are not near ſo full of Salts, as thoſe Shells which are taken from the Shore; therefore where the latter can be obtained, they are to be preferred to the former.

Where the Land lies near the Sea, ſo that either Sand, Shells, Corals, Wrecks or Sea Weeds can be obtained at an eaſy Expence, they are by far the beſt Kinds of Manure, becauſe they enrich the Land for ſeveral Years; for as their Salts are cloſely locked up, ſo they are communicated by degrees to the Land, as the Heat and Cold cauſes the Bodies to pulveriſe, and fall into ſmall Parts. So that where Sand and the ſmaller Kinds of Sea Weeds are uſed, if they are laid on the Land in proper Quantities, it will enrich it for ſix or ſeven Years; but Shells, Corals, and other hard Bodies, will continue many Years longer.

In Dunging of Land, I have frequently obſerved in ſeveral Parts of *England*, but eſpecially in *Cambridgeſhire*, a very wrong Practice; for the Dung is laid on the Land before Midſummer, and ſpread abroad perhaps a Month or ſix Weeks before the Ground is ploughed; in which Time the Sun exhales all the Goodneſs of the Dung, ſo that what remains is of little Service to the Land. Therefore when Dung or any other ſoft Manure is uſed, it ſhould not be laid on the Ground until the laſt Time of ploughing, when it ſhould be buried as ſoon as poſſible, to prevent the Evaporation of the Salts. Indeed where Shells, Corals, or any other hard Subſtances, are uſed for Manure, if theſe are ſpread abroad ſome Months before the Ground is ploughed, the Sun, Rain, or Froſt will cauſe them to pulveriſe, much ſooner than when they are buried and excluded from the Air.

MAPLE. *Vide* Acer.

MARACOCK. *Vide* Granadilla.

MARANTA, *Indian* Arrow-root.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is almoſt funnel-ſhaped, opening in ſix Parts, three of which are alternately larger than the other. The lower Part of the Flower-cup afterwards becomes an oval-ſhaped Fruit, conſiſting of one Cell, in which is one hard rough Seed.

The *Species* are;

1. MARANTA *arundinacea, cannacori folio. Plum. Nov. Gen.* Reed-like *Indian* Arrow-root, with a Leaf like the flowering Reed.
2. MARANTA *cannacori folio, flore minimo albo. Houſt. Indian* Arrow-root, with a Leaf like the flowering Reed, and the leaſt white Flower.

The firſt Sort was diſcovered by Father *Plumier* in ſome of the *French* Settlements in *America*, who gave it the Name, in Honour to one *Bartholomew Maranta* an ancient Botaniſt. The Seeds of this Kind were ſent to *Europe* by the late Dr. *William Houſtoun*, who found the Plant growing in Plenty near *La Vera Cruz* in *New Spain*.

The other Sort was brought from ſome of the *Spaniſh* Settlements in *America*, into the Iſlands of *Barbadoes* and *Jamaica*, where it is cultivated in their Gardens as a medicinal Plant, it being a ſovereign Remedy to cure the Bite of Waſps, and to expel the Poiſon of the Machineel Tree. The *Indians* apply the Root to expel the Poiſon of their Arrows, which they uſe with great Succeſs. They take up the Roots, and after cleanſing them from Dirt, they maſh them, and apply it as a Poulteſs to the wounded Part, which draws out the Poiſon, and heals the Wound. It will alſo ſtop a Gangreen, if it be applied before it is gone too far, ſo that it is a very valuable Plant.

Theſe Plants being Natives of a warm Country, are very tender, ſo will not live in this Country, unleſs they are preſerved in Stoves. They may be propagated by their creeping

Roots, which ſhould be parted in the Middle of *March*, juſt before they begin to puſh out new Leaves. Theſe Roots ſhould be planted in Pots filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners Bark, obſerving now and then to refreſh them with Water; but it muſt not be given to them in large Quantities; for too much Moiſture will ſoon rot the Roots, when they are in an unactive State. When the green Leaves appear above Ground, the Plants will require more frequently to be watered, and they ſhould have free Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are placed. As the Plants advance in Strength, ſo they ſhould have a greater Share of Air, but they muſt conſtantly remain in the Stove plunged in the Tan, otherwiſe they will not thrive; for when the Pots are placed on Shelves in the Stove, the Moiſture paſſes too ſoon from the Fibres, which generally are ſpread to the Sides and Bottoms of the Pots, ſo that the Plants do not receive much Nouriſhment from the Water. But where they are conſtantly kept in the Tanners Bark, and have proper Air and Moiſture, they will thrive, ſo as from a ſmall Root to fill the Pot in which it was planted, in one Summer. About *Michaelmas* the firſt Sort will begin to decay, and in a ſhort Time after, the Leaves will die to the Ground; but the Pots muſt be continued all the Winter in the Bark-bed, otherwiſe the Roots will periſh; for altho' they are in an unactive State, yet they will not keep good very long, when taken out of the Ground; and if the Pots are taken out of the Tan, and placed in any dry Part of the Stove, the Roots often ſhrivel and decay; but when they are continued in the Tan, they ſhould have but little Water given to them, when their Leaves are decayed, leſt it rot them. This firſt Sort doth flower conſtantly in *July* and *Auguſt*, and many times will produce ripe Seeds in *England*; but the ſecond Sort doth not flower ſo conſtant, nor do the Flowers appear ſo conſpicuous, being very ſmall, and of a ſhort Duration. This Sort never produced any Seeds in *England*, nor could I ever obſerve any Rudiment of a Seed-veſſel ſucceeding the Flower. The green Leaves abide on this Sort moſt Part of the Winter, ſeldom decaying till *February*, and ſometimes will continue green, until freſh Leaves come up, and thruſt the old ones off; in which Particular there is a more remarkable Difference between the two Sorts, than can be obſerved in the Face of the Plants.

MARCH.

Work to be done in the KITCHEN GARDEN.

The Weather in this Month is generally more unſettled than in any other Month of the Year; ſometimes it proves dry and froſty; at other Times cold and wet, with Storms of Hail and ſtrong Winds, which makes a diligent Attendance upon the Hot-beds of Cucumbers and Melons abſolutely neceſſary; otherwiſe they often miſcarry, or at leaſt loſe all their firſt Crop of Fruit: To avoid which, if your Beds have very much declin'd their Heat, you ſhould add a Lining of new Horſe-dung round the Sides, which will renew the Heat of the Beds; and alſo obſerve to cover the Glaſſes cloſe with Mats every Night; but in the Day-time they muſt have freſh Air, in proportion to the Heat of the Beds, whenever the Weather will permit, without which the Fruit will drop off, and come to nothing.

Sow Cabbages, Savoys, and Red Cabbages for Winter Uſe, (if it were not done the laſt Month) and plant out all your Cauliflower Plants which are remaining in the Winter-beds; and thoſe Cauliflower Plants which were rais'd the laſt Month, to ſucceed thoſe rais'd in Autumn, ſhould now be prick'd out upon freſh Hot-beds, to bring them forward; but they ſhould not be too cloſely cover'd, becauſe it will draw them up weak, and ſpoil them.

Continue to put in Beans and Peaſe every Fortnight, that there may be a Succeſſion of them thro' the Seaſon; and ſow Radiſhes, Spinach, and young Sallet Herbs to ſucceed thoſe before ſown; and ſow ſome Celery Seed for a latter Crop.

You may yet ſow Parſnips, Carrots, Onions, Leeks, Beets, Borage, Bugloſs, Burnet, Dill, *&c.* But theſe ſhould be ſown early in the Month, eſpecially if the Soil is dry, otherwiſe they ſeldom grow large; but upon a moiſt Soil, the Middle or latter End of the Month is Time enough.

Slip and plant Mint, Tarragon, Penny-Royal, Camomile, Balm, Savory, Sage, Roſemary, Hyſſop, Lavender Cotton, Spike Lavender, Wormwood, Southernwood, and moſt other Aromatick Plants, which are now beginning to ſhoot, and will take Root better than at any other Time of the Year.

You may now ſlip the Off-ſets from the old Roots of Skirrets, and plant them in Rows ten Inches aſunder, and ſix Inches Diſtance in the Rows, obſerving in dry Weather to water them until they have taken Root.

Your large Kind of Lettuce Plants, which have ſtood the Winter in warm Borders, muſt now be planted out into a more open Expoſure, otherwiſe they will draw up weak and come to little. You muſt alſo ſow ſome Seeds of the Sileſia, Cos, Imperial, and other Lettuces in an open rich Spot of Ground, to ſucceed thoſe of the laſt Month's Sowing; and ſow ſome Endive to come early in Summer.

About the Middle of this Month you muſt fork the Aſparagus Beds, being very careful not to hurt the Crown of the Roots; but you may defer raking them ſmooth till the Beginning of next Month, whereby you will retard the Growth of Weeds; and that will be early enough, provided it be done before the Buds appear above-ground; for the only Danger attending this late Dreſſing, is, the deſtroying of the Buds.

Toward the latter End of this Month, you may plant new Aſparagus Beds, if the Ground be dry; but if it be wet, it will be better to defer it till the Beginning of next Month.

Continue to make Hot-beds for Cucumbers, Melons, Purſlain, *&c.* and the Beginning of the Month ſow Cucumber and Melon Seeds, to ridge out under Bell or Hand-glaſſes, for the principal Crop.

Dreſs your Artichokes, obſerving to leave only two or three of the cleareſt and beſt ſituated Plants upon each Root to bear, and ſlip the reſt clean off; the beſt of which may be now planted to make a new Plantation; and theſe will produce Heads in Autumn, after thoſe upon the old Roots are gone.

Sow Chardoons upon a Bed of rich light Earth, pretty thin, obſerving to keep them clear from Weeds; and in dry Weather they muſt be water'd until they are big enough to tranſplant.

Toward the latter End of this Month you may put in ſome Kidney-Beans in warm Borders, where they may be defended from Cold; but this muſt not be done in wet Weather, becauſe too much Moiſture at this Seaſon will rot them.

You ſhould alſo ſow Sweet-Marjoram, Thyme, Hyſſop, and other tender Aromatick Plants, upon a dry warm Soil; for they will not do well on a wet Ground.

Continue to ſow all Sorts of young Sallet-Herbs, as Creſſes, Muſtard, Rape, Radiſh, *&c.* upon warm Borders until the latter End of the Month, when they will do better in a more open Expoſure.

At the End of this Month you may ſow Purſlain upon warm Borders, in the common Ground, where it will at that Time do well without any artificial Heat. You may alſo at this Time ſow Turnips, upon an open Spot of Ground to come in *May*.

You muſt now ſow the Seeds of Finnochia in Drills made about a Foot aſunder, into which the Seeds ſhould be thinly ſcatter'd, and cover'd over about half an Inch thick with light Earth. This ſhould have a rich light Soil, otherwiſe it will not ſucceed well.

Products of the KITCHEN GARDEN.

Winter Spinach in great Plenty, ſome Cabbages and Savoys are yet remaining; Sprouts from the Stalks of Cabbages and Savoys in great Plenty, and very good; Broccoli, Coleworts, Borecole, Red Beets, Chard Beets, Carrots, Parſnips, Turnips, Potatoes, Jeruſalem Artichokes, Celery, Endive, and all Sorts of young Sallet Herbs; and upon the Hot-beds, Cucumbers, Aſparagus, Peaſe, Kidney-Beans, Purſlain, *&c.* You have alſo on warm Borders, Mint, Tarragon, Tanſey and Clary, with Sage, Parſley, Marygolds, and other Kinds of Pot-herbs.

Work to be done in the FRUIT GARDEN.

You muſt now finiſh Pruning all your tender Sorts of Fruit-trees, as Peaches, Apricots, Nectarines, *&c.* for their Buds by this Time (if the Spring has been mild) will be very turgid, and in Danger of being rubb'd off, in nailing the Branches. When you have finiſh'd the pruning and nailing of the Trees, the Ground ſhould be dug about their Roots to looſen it and deſtroy the Weeds. And when the Trees are in Bloſſom, if the Weather ſhould prove very ſharp, and the Nights froſty, it will be proper to cover them with Mats, Canvas, or Reeds, to guard them from Injury; but theſe Coverings ſhould be taken off at all Times when the Weather is mild, otherwiſe they will force out the Shoots too ſoon, and render the Bloſſoms ſo weak, that the leaſt inclement Weather will deſtroy them: It will alſo be proper, in very dry Seaſons, to ſprinkle ſome Water gently over the Branches of your Fruit-trees (eſpecially in mild Weather) which will ſtrengthen the Bloom, and forward the Fruit, and alſo be of great Service to the Trees.

You may yet tranſplant Fruit-trees upon a moiſt Soil; but if your Ground be not ready by the Middle of the Month to receive them, it will be proper to take them up and prune their Roots, and then lay them in the Ground, covering their Roots and Stems with Litter, to prevent their being dry'd by the Sun and Wind; this will retard their Shooting, and their Roots will be prepar'd for puſhing, by which Method there will be little Danger of their ſucceeding.

This is the principal Month for grafting moſt Sorts of Fruit-trees, beginning with the early Kinds, and ending with Apples; but this muſt be perform'd earlier or later, according to the Seaſon.

Cut off the Heads of thoſe Stocks which were inoculated the laſt Summer, leaving about four Inches above the Bud to attract the Sap; (and, if need be, to faſten the Shoot to, to prevent its being blown out) and after this is done, the Ground between the Trees ſhould be dug to bury the Weeds and looſen it, for the Roots of the Plant to find Nouriſhment.

Dreſs and freſh earth your Beds of Straw-berries, pulling off their Strings, and clearing them from Weeds, which will cauſe them to produce a greater Quantity of Fruit: and dig between the Rows of Raſpberries (where it was not before done) to make the Ground clean, and looſen it, that the Roots of the Plants may penetrate the better into it.

Your Fruit-trees which were planted the laſt Autumn, with their Heads intire, ſhould now be headed down to three or four Eyes; in doing of which you muſt be very careful not to diſturb their Roots: To prevent which, you ſhould place your Foot cloſe to the Stem, and hold the lower Part of the Tree faſt with your Left-hand, while, with a ſharp Knife in your Right-hand, you cut off the Head. You ſhould alſo cover the Ground carefully with Mulch, or rather with ſome Green-ſward, turning the Graſs downward, which will prevent the Sun and Wind from penetrating the Ground to their Roots, the Neglect of which has deſtroy'd many new-planted Trees.

Thoſe Trees which were grafted the former Spring, and are yet remaining in the Nurſery, ſhould be ſhorten'd to four or five Eyes, that they may be furniſh'd with lateral Branches near the Ground, otherwiſe they will run up tall, and become naked at Bottom.

Dig and clear the Ground between your Gooſeberries and Currants, which will ſtrengthen their Bloſſoms, and incourage the Trees, and add a Neatneſs to the Place.

Fruits in prime, or yet laſting.

Pears; Bergamot Bugi, St. Martial, Winter Boncretien, Double-fleur, Royal d'Hyver, Bezy de Chaumontelle, L'Amozelle; and for baking, the Cadillac, *Parkinſon*'s Warden, Union or Pickering, with ſome others.

Apples; Loan's Pearmain, Nonpareil, Golden Ruſſet, Pile's Ruſſet, Wheeler's Ruſſet, Kentiſh Pippen, Holland Pippen, French Pippen, Pomme d'Api, Stone Pippen, John Apple, with ſome others.

Work to be done in the FLOWER GARDEN.

In this Month you may tranſplant moſt Sorts of fibroſe-rooted Plants, as Carnations, Pinks, Sweet Williams, Roſe Campions Lychnis's, Thrift, Aſter's, Golden Rods, Perennial Sun-Flowers, Canterbury-Bells, Peach-leav'd Bell-flower, French Honey-ſuckles, Daizies, Buphthalmums, Leucanthemums, Columbines, Hieracium's, with many other Sorts; tho' if the Soil be dry, it would have been better if done at *Michaelmas*, becauſe they would have taken Root in the Ground, and ſo be better enabled to reſiſt the Drought, and alſo to produce a greater Quantity of Flowers.

Stir the Earth of your Borders, and Beds of Flowers which were planted at *Michaelmas*, with a narrow Trowel, and be very careful in doing of this, not to injure the Roots, nor the Flower-buds, which now begin to appear; this will prevent the Growth of Weeds, and when raked over ſmooth, will render the Beds more agreeable to the Eye.

Your choice Hyacinths, Anemonies, Ranunculus's and Tulips, will now begin to ſhew their Flower-buds, when they ſhould be carefully covered with Mats or Canvas in bad Weather; for at this Seaſon the Nights are often Froſty, and if the Flowers are expos'd, their Buds are frequently pinch'd, ſo that they will not open ſo fair, as thoſe which are protected.

Plant ſome Roots of common double Anemonies to flower late, after thoſe which were planted in Autumn are paſt, and if the Seaſon ſhould prove dry, refreſh them now and then with Water, otherwiſe they will not ſucceed well.

The Boxes and Pots with ſeedling Auricula's ſhould now be placed in a ſhady Situation; for the Plants will begin to appear, and if they are expoſed to the full Sun but one Day, while they are young, it will deſtroy moſt of them: You muſt alſo refreſh them with Water in dry Weather, but give it to them very gently, leſt you waſh them out of the Ground.

Your Pots of choice Auricula's muſt now be taken Care of, to protect them from blighting Winds and froſty Nights, which will otherwiſe pinch their Flower-buds, and ſpoil their Blowing: You muſt alſo refreſh them now and then with Water in dry Weather, but do not let the Wet get into the Center of the Plants, leſt it injure the Flower-ſtems.

Dig up the Ground in your Wilderneſs Quarters, and between flowering Shrubs, if it hath not been done the former Month: This will looſen the Ground, and encourage the Shrubs to flower ſtrongly, and render the Place free from Weeds, for Neatneſs is always to be deſired in every Part of a Garden.

Give freſh Earth to the Carnations which were planted out for good at *Michaelmas*, and pick off all decay'd Leaves; this will greatly ſtrengthen them for flowering.

Your Pots of double Roſe Campions, Campanula's, Scarlet Lychnis's, *&c.* which were planted at *Michaelmas*, ſhould alſo be pick'd from all dead Leaves and Filth, and the Earth on the Tops of the Pots taken out, and the Pots refilled with freſh rich Earth, which will ſtrengthen them greatly for flowering.

Toward the latter End of the Month you may ſow the Seeds of all hardy Annual Flowers, in the Borders of the Pleaſure Garden; ſuch as Flos-Adonis, Venus Looking-glaſs, Venus Navelwort, Sweet-ſcented Peaſe, Tangier Peaſe, Lobel's Catchfly, Dwarf Lychnis, Dwarf Annual Stock, Candy Tuft, Oriental Mallow, Lavatera's, Ketmia Veſicaria, Convolvulus Minor, with many others. The beſt Method is to ſow the Seeds thin in little Patches, where they are to remain, for they do not ſucceed ſo well when they are tranſplanted.

You may now ſow the Seeds of many Kinds of biennial and perennial Plants in your Flower Nurſery, to ſupply the Borders of the Flower Garden the following Year, as Columbines, Canterbury-Bells, French Honey-ſuckles, Stock-Gilliflowers, Wall-Flowers, Sweet-Williams, with ſome others. And this is a proper Seaſon for ſowing your choice Carnation and Pink Seeds, being careful not to bury the Seeds deep in the Ground, and place the Pots or Tubs where they may have the Morning Sun. Upon a moderate Hot-bed, you may now ſow the Seeds of Marvel of Peru, French Marygold, Female Balſamine, Love Apple, African Convolvulus Major, Capſicums, Stramoniums, Indian Pink, Sweet Sultan, and many other Sorts, which are indifferent hardy, but require a little Warmth, to bring 'em forward in the Spring, yet if ſown too early, are apt to grow too large before the Seaſon will be favourable enough to tranſplant them abroad.

Make freſh Hot-beds for your choice Sorts of Annual-Plants, which were ſown the former Month, and let the Earth upon theſe Beds be very good, for otherwiſe your Plants will not thrive well; when the Heat of the Beds is moderate, the Plants ſhould be placed into them, allowing them proper Diſtances to grow; and obſerve to refreſh them with Water, as they ſhall require, by which Method your Amaranthus's, and other Sorts of curious Annuals may be brought to a large Size.

Toward the End of the Month, if the Seaſon be mild, and inclinable to Wet, you may tranſplant moſt Sorts of Evergreens, as Hollies, Yews, Phillyrea's, Alaturnus's, Laurels, Bays, Lauruſtinus's, *&c.* with many Kinds of exotick Trees, obſerving to cover the Surface of the Ground with Mulch, to prevent the Sun and Wind from penetrating the Ground and drying their Roots; but if this Month be cold, and North or Eaſt Winds reign, with dry Weather, it will be better to wait till next Month, for more favourable Weather.

You may now ſow the Seeds of Firs, Pines, Bays, Cedars, Arbutus's, Alaturnus's, Phillyrea's, and other Evergreen or hardy exotick Trees, in ſuch Places where they be expos'd only to the Morning Sun.

Plants now in Flower in the PLEASURE GARDEN.

Crocus's of various Sorts, Double Snow-Drop, Large Snow-Drop, ſeveral Sorts of Narciſſus's, Perſian Iris, Double Pilewort, Daffodil, Spring Cyclamen, Early Tulips, Crown Imperials, Hyacinths of ſeveral Sorts, Fennel-leav'd perennial Adonis, ſome Anemonies, Violets, Hepatica's, Wall-flowers, Allyſon, perennial Fumitory, Primroſes, Polyanthus's, Daizies, Dens Canis, Muſcari, with ſome others.

Hardy Trees and Shrubs now in Flower.

Almond-tree, Cherry Plum, Mezerions, Spurge Laurel, Lauruſtinus, Spaniſh Traveller's Joy, Cornelian Cherry, Benjamin-tree, Willow-leav'd Sea Buckthorn, with ſome others.

Work to be done in the GREEN-HOUSE *and* STOVE.

Water your Orange-trees, Myrtles, Bays, Amomum Plinii, and other leſs tender exotick Trees, frequently, but do not give it to them too plentifully ; and begin to inure them to the Air by Degrees, opening the Glaſſes whenever the Air is ſoft and mild ; but in cold Days, or when the Air is ſharp, it ſhould not be admitted to them ; for by being made tender by the Houſe, a little ſharp Air will be prejudicial to them, until they are become a little hardier.

Waſh and cleanſe the Leaves and Stems of your Orange-trees from the Filth which they have contracted, during their Confinement in the Houſe, and take the Earth out from the Tops of the Tubs or Pots ; filling them up again with freſh rich Earth, which will ſtrengthen them greatly, and prepare them for flowering.

Toward the End of this Month (if the Weather be favourable) you may take out your Tubs of Bays, Oleanders, Lauruſtinus's, Lentiſcus, and other hardy Kinds, placing them near a Hedge, in a Situation where they may be well defended from cold Winds ; and this will thin the Houſe of Plants and give Room to thoſe that remain, to have a greater Share of free Air.

If any of your Orange-trees have decay'd Heads, they ſhould now be ſhifted and pruned in cloſe, and placed upon a Hot-bed of Tanners-bark, to force them out again ; treating them in the Manner directed in the former Month.

You may alſo head down ſuch Myrtles, Bays, and Lauruſtinus's, as have ragged or decay'd Heads, obſerving to give them a very moderate Warmth, juſt to make them puſh again, and then let them have as much free Air as poſſible. By this Method you may renew their Heads, which, with often Pruning, may be reduced into exact Order, and the Trees rendered beautiful.

Sow the Kernels of Oranges, Lemons, and Citrons, for Stocks to bud the ſeveral Kinds of thoſe Fruits upon ; if theſe are taken from rotten Fruits, they are better than thoſe from ſound ones ; and they ſhould be ſown upon moderate Hot-beds, refreſhing them often with Water, which will bring them on prodigiouſly ; but in very hot Weather the Glaſſes ſhould be cover'd with Mats.

Make ſome Hot-beds of Tanners-bark in order to tranſplant ſuch tender exotick Plants as are come up from the Seeds ſown the former Month ; and when the Beds are in due Order, you ſhould fill ſome ſmall Pots with freſh rich Earth, and plunge them into the Beds, that the Earth may become warm before the Plants are placed therein, which ſhould be done the Day after the Pots are plunged, otherwiſe the Earth will become too dry : When the Plants are planted, they muſt be gently watered, and the Glaſſes ſhaded until they have taken Root ; after which they ſhould be frequently refreſh'd with Water, and the Air muſt be let into the Beds proportionably to the Warmth of the Seaſon.

The Fires in the Stoves ſhould now be abated ; but this muſt be done by Degrees, according as the Weather increaſes in Warmth.

Your Anana's or Pine-Apples muſt now be removed into Bark-beds ; therefore, if you have not prepar'd your Beds ready to receive them, it ſhould be no longer delay'd ; for the Bloſſoms of the Fruit will now begin to appear ; and if the Plants are check'd at that Time, their Fruit is ſeldom ſo fair, nor ſo early ripe.

Stir up the Bark-beds in the Stove, where wanted, and clean the Leaves of your Coffee-tree and other woody Plants, from the Filth they may have contracted, and pick off all decay'd Leaves, which, if ſuffer'd to remain on, do greatly injure the Plants.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Ficoides's of ſeveral Sorts, Ilex-leav'd Jaſmine, Spaniſh Jaſmine, Hermannia alni folio, Anemonoſpermos's two or three Kinds, Polygala Africana fruteſcens buxi folio, Aleppo Cyclamens, Geraniums, Hermannia Ibiſci folio, Doria Africana atriplicis folio, Chryſanthemum populi albæ folio, Aloes of ſeveral Sorts, Coronilla Cretica argentea, Sedum arboreſcens, Lilio Narciſſus, Pancratium, Turnera, Cotyledon with a broad cut Leaf, with ſome others.

MARJORAM. *Vide* Majorana.

MARLE, is a Kind of Clay, which is become fatter, and of a more inriching Quality by a better Fermentation, and by its having lain ſo deep in the Earth as not to have ſpent or weaken'd its fertilizing Quality by any Product.

Marle is ſuppos'd to be much of the Nature of *Chalk*, and is believ'd to be fertile from its ſalt and oily Quality, and that it contracts its Salts from the Air, and for that Reaſon is the better the longer it is expos'd to it.

Marles are of different Qualities in different Counties of *England*. There are reckon'd to be four Sorts of *Marles* in *Suſſex*, a Grey, a Blue, a Yellow, and a Red : Of theſe the Blue is accounted the beſt, the Yellow the next, and the Grey the next to that ; and as for the Red, that is the leaſt durable.

The *Marle* in *Suſſex* is moſt like Fuller's-Earth, and therefore muſt certainly be the fatteſt ; whereas that in the *North-Country* runs much upon the Loam.

In *Cheſhire* they reckon ſix Sorts of *Marle* :

1. The *Cowſhut Marle*, which is of a browniſh Colour, with blue Veins in it, and little Lumps of Chalk or Lime-ſtone : It is commonly found under Clay or low black Land ſeven or eight Feet deep, and is very hard to dig.

2. *Stone*, *Slate*, or *Flag-Marle*, which is a Kind of ſoft Stone, or rather Slate of a blue or bluiſh Colour, that will eaſily diſſolve with Froſt or Rain : This is found near Rivers and the Sides of Hills, and is a very laſting Sort of *Marle*.

In *Staffordſhire* they eſteem the *Dice* or *Slate-Marle* better than the *Clay-Marle*, and reckon the Blue beſt for Arable-Land, and the Grey for Paſture.

3. *Peat-Marle*, or *Delving-Marle*, which is cloſe, ſtrong, and very fat, of a brown Colour, and is found on the Sides of Hills, and in wet or boggy Grounds, which have a light Sand in them about two Feet or a Yard deep : This is accounted the ſtrongeſt of all *Marles*, and is very good for ſandy Land, but the Land muſt have a double Quantity laid on.

4. *Clay-Marle* ; This reſembles Clay, and is pretty near akin to it, but is fatter, and ſometimes mix'd with Chalk-ſtones.

5. *Steel-Marle* ; which lies commonly in the Bottom of Pits that are dug, and is of itſelf apt to break into cubical Bits : This is ſometimes under ſandy Land.

6. *Paper-Marle* ; which reſembles Leaves or Pieces of brown Paper, but ſomething of a lighter Colour : This lies near Coals. This Sort is leſs eſteem'd, it being hard to be got.

The Properties of any Sorts of *Marles*, and by which the Goodneſs of them may be beſt known, are better judg'd of by their Purity and Uncompoundedneſs, than their Colour ; as if it will break in Pieces like Dice, or into thin Flakes, or is ſmooth like Lead-Ore, and is without a Mixture of Gravel or Sand ; if it will flake like Slate-ſtones, and ſhatter after Wet, or will turn to Duſt when it has been expos'd to the Sun ; or will not hang and ſtick together when it is thoroughly dry, like tough Clay ; but is fat and tender, and will open the Land it is laid on, and not bind ; it may be taken for granted that it will be beneficial to it.

Some adviſe, to try the Goodneſs of *Marle*, by putting ſome of it into a Glaſs of Water ; and they account it to be good, if it be ſo tender that the Lumps break and diſſolve as ſoon as it comes to the Bottom : They alſo reckon it a good Sign, if it ſparkle in the Water, and feel fat between the Fingers ; but the ſureſt Sign of its Goodneſs, is, if it diſſolve by Wet or Froſt.

Some approve of marling Land ſhallow, becauſe, they ſay, it is apt to work downwards : Others, of laying it in deep at firſt, becauſe the Sun waſtes the Fatneſs of it.

Some recommend *Marles* for the improving of ſandy looſe Land : But the ſureſt way to know what Lands it will ſuit beſt with, is, to try with a little of it on Lands ſuppos'd to be of a contrary Nature to it.

Marles do not make ſo good an Improvement of Lands the firſt Year, as afterwards.

Some adviſe, firſt to burn the *Marle* before it is laid on the Lands, which, if it be done, one Load will go as far as five.

The Quantity of the *Marle* ought to be in Proportion to the Depth of the Earth ; and Over-marling has often prov'd of worſe Conſequence than Under-marling.

MARRUBIASTRUM: Baſtard Horehound.

The *Characters* are;

It is one of the Verticillate Plants with a Lip-flower, conſiſting of one Leaf, whoſe Upper Lip is hollow like a Spoon, but the Lower Lip (or Beard) is cut into three Segments: Out of the Centre of the Flower riſes the Pointal, attended, as it were, by four Embryo's, which afterwards turn to ſo many roundiſh Seeds. To which may be added, The little Flower-cup is cut into five ſmall Segments, upon which are produc'd ſmall Spines; and the Flowers grow in thick Whorles round the Stalk.

The *Species* are;

1. Marrubiastrum *vulgare. Tourn.* Common Baſtard Hore-hound.
2. Marrubiastrum *ſideritidis folio, caliculis aculeatis, flore candicante. Tourn.* Baſtard Hore-hound, with an Ironwort Leaf, and a white Flower.
3. Marrubiastrum *ſideritidis folio, caliculis aculeatis, flore flavo cum limbo atro-purpureo. Tourn.* Baſtard Hore-hound, with an Ironwort Leaf, and a yellow Flower with a dark purple Edge.
4. Marrubiastrum, *folio cardiacæ. Boc. Muſſ.* Baſtard Hore-hound, with a Motherwort Leaf.

The firſt of theſe Plants is found wild amongſt the Corn in *Kent*, and ſome other Counties in *England*, and is ſeldom cultivated, except in Botanic Gardens, for the ſake of Variety, where are alſo ſome other Species of this Plant preſerved for the ſame Purpoſe.

The other three Sorts are found wild in the Southern Parts of *France* and *Italy*, from whence the Seeds have been ſent to the Curious in Botany in divers Parts of *Europe*.

Theſe Plants may be all propagated by ſowing their Seeds as ſoon as they are ripe, upon a Bed of light dry Soil, where they will come up the ſame Autumn, and abide the Cold of our ordinary Winters very well, and may be tranſplanted out in the Spring where they are to remain. In *June* they will flower, and their Seeds will be ripe in *July* or *Auguſt*.

MARRUBIUM; [Some derive the Name of מריב, Heb. *Marrob*, i. e. *bitter Juice*; others, from the Latin Word *Marcidum*, becauſe the Leaves of this Plant are ſo wrinkled that they appear to be withering] Hore-hound.

The *Characters* are;

It is a verticillate Plant with a Lip-Flower conſiſting of one Leaf, whoſe Upper-Lip (or Creſt) is upright with two Horns; but the Under-Lip (or Beard) is divided into three Parts; the Pointal, which is fix'd to the Hinder-Part of the Flower, is attended by four Embryo's, which become ſo many oblong Seeds, incloſ'd in the Flower-cup.

The *Species* are;

1. Marrubium *album vulgare. C. B. P.* Common White Hore-hound.
2. Marrubium *album latifolium peregrinum. C. B. P.* Broad-leav'd Foreign White Hore-hound.
3. Marrubium *album anguſtifolium peregrinum. C. B. P.* Narrow-leav'd Foreign White Hore-hound.
4. Marrubium, *alyſſon dictum, foliis profunde inciſis. H. L.* Hore-hound, call'd Madwort, with Leaves deeply cut in.
5. Marrubium *Hiſpanicum ſupinum, foliis ſericeis argenteis. Tourn.* Low Spaniſh Hore-hound, with ſilken ſilver-colour'd Leaves.

There are ſome other Species of this Plant, which are preſerv'd in curious Botanick Gardens, for the ſake of Variety: but as they are of no Uſe or Beauty, ſo it would be needleſs to enumerate them in this Place.

The firſt Sort here mention'd is us'd in Medicine: This is found wild in divers Parts of *England*. The other Sorts are only kept by ſuch as delight in Variety of Plants; for they have no great Beauty in their Flowers, nor are there any Uſes to which they are applied.

They may all be propagated by ſowing their Seeds in *March* upon a Bed of freſh light Earth, and when they are come up, they ſhould be tranſplanted out into a dry Soil, at about eighteen Inches or two Feet aſunder, where they will require no farther Culture than only to keep them clear from Weeds. But the fourth Sort is ſomewhat tender, and ſhould have a warm Situation, otherwiſe it would be often kill'd by Froſts.

MARRUBIUM NIGRUM. *Vide* Ballote.

MARTAGON. *Vide* Lilium.

MARTYNIA.

This Name was given by the late Dr. *William Houſtoun* to this Genus of Plants, which he diſcovered in *America*, in Honour to his Friend Mr. *John Martyn*, Profeſſor of *Botany* at *Cambridge*.

The *Characters* are;

It hath an anomalous Flower conſiſting of one Leaf, which is divided into two Lips: the Upper Lip is erect, and ſlightly cut into two Parts; but the Under Lip is cut into three Parts, the Middle Segment being larger than the other two. The Flower is ſucceeded by a Fruit having a ſtrong thick Covering, in which is included a very hard Nut, having two ſharp crooked Horns at one End; and in the Nut are included four Seeds, lodged in ſo many ſeparate Cells.

The *Species* are;

1. Martynia *annua villoſa & viſcoſa, folio ſubrotundo, flore magno rubro. Houſt.* Annual hairy viſcous Martynia, with a roundiſh Leaf, and a large red Flower.
2. Martynia *annua villoſa & viſcoſa, aceris folio, flore albo, tubo longiſſimo. Houſt.* Annual hairy viſcous Martynia, with a maple Leaf, and a white Flower, having a very long Tube.
3. Martynia *perennis, folio ſubrotundo rugoſo, flore cæruleo, radice dentariæ. Linn.* Perennial Martynia, with a rough roundiſh Leaf, a blue Flower, and a Toothwort Root.

The firſt of theſe Plants was diſcovered by the late Dr. *William Houſtoun*, near *La Vera Cruz* in *New Spain*, from whence he ſent the Seeds into *England*, which ſucceeded very well in the Phyſic-Garden at *Chelſea*; and in the Year 1731, ſeveral of theſe Plants were raiſed, which produced their beautiful Flowers, and perfected their Seed; from whence ſeveral Plants were raiſed the ſucceeding Year.

The ſecond Sort was diſcovered by the ſame curious Gentleman in the Year 1733, near *Cartagena* in *New Spain*, from whence he ſent dried Samples of the Plant, with ſome of the Seeds to *England*; but they did not ſucceed.

The Seeds of the third Sort were ſent from *Carthagena* by Mr. *Robert Millar* Surgeon, from which ſome of the Plants were raiſed in the Gardens of Mr. *George Clifford* of *Amſterdam*; where they have flowered, but have not produced any Seeds in *Europe*. This Sort increaſes greatly by its Roots, which creep under Ground, ſo as to fill the Pots in which they are planted, in one Seaſon.

The two firſt Sorts being annual Plants, are only propagated by Seed, which ſhould be ſown in Pots filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark; where (if the Earth is duly water'd to promote the Vegetation of the Seed) the Plants will appear in about a Fortnight, or three Weeks, and will grow pretty faſt, if the Bed is warm: So they ſhould be tranſplanted in a little Time after they come up, each into a ſeparate Pot, filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to water them well, as alſo to ſhade them from the Sun, until they have taken new Root; after which Time they ſhould have a large Share of freſh Air admitted to them in warm Weather, by raiſing of the Glaſſes of the Hot-bed every Day, with Bricks or Stones, and the Plants muſt be frequently water'd. With this Management, the Plants will make great Progreſs, ſo as to fill the Pots with their Roots in about a Month's Time; when they ſhould be ſhifted into Pots, about a Foot Diameter at the Top, which ſhould be filled with light rich Earth, and then plunged into the Hot-bed in the Bark-ſtove, where they ſhould be allowed Room, becauſe they put out many Side-branches, and will grow three Feet high or more, according to the Warmth of the Bed, and the Care which is taken to ſupply them conſtantly with Water. About the Middle of *July*, the Plants will begin to ſhew their Flowers, which are produced in a Spike from the Top of the Plants, which, of the firſt Sort, are like thoſe of the *Fox-glove*. As the firſt Spike of Flowers decays, they are ſucceeded by Spikes from all the Side-branches; ſo that the Plants continue in Flower until *Michaelmas* or later, if the Seaſon proves favourable: But it is only from the firſt Spike of Flowers that good Seeds can be expected in this Country; ſo that particular Care ſhould be taken, that none of thoſe are pulled off or deſtroyed; becauſe it is very difficult to obtain good Seeds in this Country; and I believe few of thoſe which are produced on the Side-branches in the natural Country of their Growth, are duly ripened; for I received a great Quantity of theſe Seeds from abroad, which have appeared to be very good, and yet few of them have produced Plants.

The Seeds of theſe Plants have a ſtrong green Covering over them, as thick as the outer Covering of an Almond; and when the Seeds are ripe, the Covering opens, and lets the Seed fall, in the ſame Manner as the Covering of *Almonds*, *Walnuts*, &c. In each Covering there is one hard Nut, in Shape ſomewhat like a Beetle, having too ſharp crooked Horns at one End. This Nut contains four Embryo's; but there are ſeldom more than two Seeds which are perfect in any of them. However, when they are ſown, the whole Nut muſt be planted; for it is ſo hard, that it is impoſſible to take out the Seeds without ſpoiling of them; and where there are two Plants produced from the ſame Nut, they are eaſily ſeparated, when they are tranſplanted. Theſe Seeds will continue good for ſome Years; for I ſaved a pretty large Quantity of them in the Year 1734, Part of which I ſowed the following Year, but had not one Plant produced; the Remainder of the Seeds I divided, and ſowed ſome of them every ſucceeding Year, without any Succeſs, until the preſent Year 1738, when I ſowed all the Seeds I had left, from which I had one Plant produced. So that if the Seeds are good, it is evident they will grow when they are four Years old. Therefore, whenever we receive good Seeds from Abroad, or ſave any in this Country which are perfectly ripened, it will be proper to preſerve ſome of them for a Year or two, leſt a bad Seaſon ſhould happen, when the Plants may not perfect their Seeds; ſo that if this Precaution be not taken, the Species may be loſt in *Europe*.

The third Sort dies to the Root every Winter, and riſes again the ſucceeding Spring; this muſt be conſtantly preſerved in the Stove, and plunged into the Bark-bed, otherwiſe it will not thrive in this Country. During the Winter-ſeaſon, when the Plants are decayed they ſhould have but little Water given to them; for Moiſture at that Time will rot the Roots. In the Beginning of *March*, juſt before the Plants begin to ſhoot, is the proper Seaſon to tranſplant and part the Roots; when they ſhould be planted into Pots of a Middle Size, filled with light rich Earth, and then plunged into the Bark-bed, which ſhould at this Time be renewed with freſh Tan. When the Plants come up, they muſt be frequently refreſhed with Water; but it muſt not be given to them in large Quantities, leſt it rot their tender Roots; and as the Warmth of the Seaſon increaſes, it will be proper to admit a large Share of freſh Air, which will greatly ſtrengthen the Plants; but they muſt conſtantly remain in the Stove, otherwiſe they will not produce Flowers in this Country. The Time of their Flowering is in the End of *July*, and in *Auguſt*; and in *October*, the Plants die to their Roots.

MARVEL OF PERU. *Vide* Jalapa.

MARUM, [of *Amarum*, Lat. *Bitter*, becauſe this Plant is very bitter] Maſtick.

The *Characters* are;

It is a Plant with a Lip-Flower, conſiſting of one Leaf, but has no Galea (or Creſt) the Stamina *ſupplying the Place of it; but the Under-Lip is divided into five large Segments, the middlemoſt of which is hollow like a Spoon; theſe Flowers are produc'd ſingle from the Wings of the Leaves. To which may be added, It has the Appearance of a Shrub, and a hot volatile Smell.*

We have but one *Species* of this Plant, at preſent, in *England*, which is,

Marum *Syriacum vel Creticum. H. L.* Syrian Maſtick, *vulgo*.

This Plant is propagated by planting Cuttings, in any of the Summer Months, upon a Bed of freſh light rich Earth, obſerving to water and ſhade them, until they have taken Root; after which, they may be tranſplanted either into Pots or Borders of the ſame freſh light Earth: But the greateſt Difficulty is, to preſerve it from the Cats, who will come from a great Diſtance to tear this Plant in Pieces, and from whom there is ſcarcely any guarding it, eſpecially near Towns and Cities, where there are many of theſe Animals, unleſs by planting large Quantities of it; for it is obſervable, that where there are but few of them, the Cats will not leave them, until they have quite demoliſh'd them; whereas, when a large Quantity of the Plants are ſet in the ſame Place, they will not come near them.

Thoſe Plants, which are put into Pots, ſhould be ſhelter'd in Winter; but thoſe in the full Ground, will abide the Cold of our ordinary Winters very well, provided they are planted on a warm dry Soil; and may be clipt into Pyramids or Balls, in which Figures I have ſeen ſome Plants of this Kind near three Feet high, which have endur'd the open Air ſeveral Years without any Covering.

MARUM VULGARE. *Vide* Maſtichina.

MARYGOLD. *Vide* Caltha.

MARYGOLD (AFRICAN). *Vide* Tagetes.

MARYGOLD (FIG). *Vide* Ficoides.

MARYGOLD (FRENCH). *Vide* Tagetes.

MASTER-WORT. *Vide* Imperatoria.

MASTICHINA, [ſo call'd, of *Maſtick*, becauſe it has perfectly both the Smell and Virtue of that Plant. It is alſo call'd *Marum*, of its Bitterneſs] Herb Maſtick, *or* Maſtick-Thyme.

The *Characters* are;

The Leaves are like thoſe of Thyme, *but larger; the Stalks are upright and ſhrubby; the Cup of the Flower is long, narrow, and tubulous, but is ſpread open at the Top, where it is cut into five long ſlender Segments, and has a Woollineſs over every Part of it; the* Galea *(or Creſt) of the Flower ſtands upright, and is divided into two Parts; the Beard (or Lower Lip) is divided into three Segments, ſo that it appears ſomewhat like a Flower with five Leaves; the Flowers are collected into thick Whorles, and have a white Down growing upon the oblong Heads.*

The *Species* are;

1. Maſtichina. *Boerh. Ind.* Herb Maſtick, or Maſtick-Thyme.
2. Maſtichina *folio minore.* Herb Maſtick, with a leſſer Leaf.

There ſeems to be another Variety of this Plant in ſome of the *Engliſh* Gardens, which is of humbler Growth than the Common Sort: The Spikes of Flowers are alſo ſhorter and looſer; but the Leaves are full as large as thoſe of the common Sort. This I don't remember to have ſeen taken Notice of in any of the Books of *Botany*, tho' it ſeems conſtantly to retain this Difference.

Theſe Plants may be propagated by planting Cuttings, during any of the Summer Months, in a Bed of light rich Earth, obſerving to water and ſhade them, until they have taken Root: After which they may be tranſplanted into a light dry Soil, and have a warm Situation, where they will endure the Cold of our ordinary Winters very well, and produce great Quantities of Flowers in *July*, but ſeldom ripen their Seeds in this Country.

The Flowering Part of this Plant is order'd as an Ingredient in *Venice Treacle*, for which Purpoſe it ſhould be propagated in *Phyſick-Gardens*. And the Plant having an agreeable Scent, and being eaſily cultivated, may merit a Place in the Borders of every good Garden, where it may be reduced to a regular Head, and will appear very handſome.

MATRICARIA, [ſo call'd, from the *Matrix*, becauſe this Plant is very good againſt Diſeaſes of the Womb: And, for the ſame Reaſon, it is call'd *Parthenium*, of Πάρθενος; a *Virgin.*] Feverfew.

The *Characters* are;

It hath a fibroſe Root; the Leaves are conjugated, and divided into many Segments; the Cup of the Flower is ſquamoſe, and hemiſpherical; the Flowers grow in an Umbel upon the Top of the Stalks, and the Rays of the Flower are for the moſt part white.

The *Species* are;

1. Matricaria *vulgaris vel ſativa. C. B. P.* Common Feverfew.
2. Matricaria *vulgaris vel ſativa, caulibus rubentibus. H. L.* Common Feverfew, with reddiſh Stalks.
3. Matricaria *vulgaris vel ſativa, floribus nudis bullatis. H. L.* Common Feverfew, with naked Flowers.
4. Matricaria *vulgaris vel ſativa, florum petalis fiſtuloſis. H. L.* Common Feverfew, with the Petals of the Flower quill'd or fiſtulous.
5. Matricaria *vulgaris vel ſativa, florum petalis fiſtuloſis & brevioribus. H. L.* Common Feverfew, with ſhor fiſtulous Petals.

6. Matricaria *flore pleno. C. B. P.* Double-flower'd Feverfew.

7. Matricaria *flore pleno, petalis fiſtuloſis. H. L.* Feverfew, with double fiſtulous Flowers,

8. Matricaria *flore pleno, petalis marginalibus planis, diſcoidibus fiſtuloſis. H. L.* Double Feverfew, with the Petals round the Border plain, but thoſe in the middle of the Flowers fiſtulous.

9. Matricaria *foliis elegantiſſime criſpis, & petalis florum fiſtuloſis. Tourn.* Feverfew, with elegant curl'd Leaves, and the Petals of the Flowers fiſtulous.

The firſt of theſe Species (which is the Sort uſed in Medicine) is found wild upon Dunghills and uncultivated Places in divers Parts of *England*, but is cultivated in thoſe Gardens which propagate medicinal Plants to ſupply the Markets. The other Sorts are preſerv'd in curious Botanick Gardens for Variety: And the ſixth, ſeventh, and eighth Sorts deſerve a Place in the Borders of large Gardens, for the Beauty of their Flowers.

Theſe Plants are propagated by their Seeds, which ſhould be ſown in *March*, upon a Bed of light Earth; and, when they are come up, they ſhould be tranſplanted out into Nurſery-beds, at about eight Inches aſunder, where they may remain till the Middle of *May*, when they may be taken up, with a Ball of Earth to their Roots, and planted in the Middle of large Borders, where they will flower in *July* and *Auguſt*; and, if the Autumn be favourable, will produce ripe Seeds the ſame Year. But it is not adviſeable to permit them to ſeed, which often weakens and decays the Roots; therefore when their Flowers are paſt, you ſhould cut down their Stems, which will cauſe them to puſh out freſh Heads, whereby the Roots will be maintain'd.

When the different Varieties of theſe Plants are intermix'd with other Plants of the ſame Growth, they make a handſome Appearance during their Seaſon of Flowering, which commonly continues a full Month, or more, and renders them very valuable. But as their Roots ſeldom abide more than two or three Years, ſo freſh Plants ſhould be rais'd from Seeds, to ſupply their Places; for altho' they may be propagated by parting their Roots either in Spring or Autumn, yet theſe ſeldom make ſo good Plants as thoſe obtain'd from Seeds. But the ſixth Sort ſeldom produces any good Seeds; therefore that muſt be propagated in this manner, or by planting Cuttings in the Spring or Summer Months, which will take Root, and make good Plants.

MATTED ROOTS, are ſuch as are entangled or platted together.

MAUDLIN. *Vide* Ageratum.

MAY.

Work to be done in the KITCHEN GARDEN.

If the Weather in this Month proves hot and dry, it greatly retards the Growth of moſt eſculent Plants; and particularly the Beans and Peaſe which are in Flower (eſpecially on dry Lands) ſuffer greatly; moſt of their Bloſſoms falling off before their Maturity, ſo that they are not ſucceeded by Fruit. But when this Month happens to be wet, the Markets are plentifully ſtock'd with moſt Sorts of Garden Ware. But this does not only increaſe the Quantity of Plants, but alſo as great Plenty of Weeds, whereby the Labour of a Kitchen-Garden is more than double of what is required in a dry Seaſon; for if the young Crops are neglected but a very ſhort Time in moiſt Weather, the Weeds will get the better of 'em, and weaken them ſo much as they will hardly recover their full Strength again, nor will the Plants (with all poſſible Care afterward) ever arrive to the Size they would have grown to, provided they had not been ſtunted by the Weeds. Beſides many Sorts of Weeds will perfect their Seeds in a ſhort Time, which being ſhed upon the Ground, will occaſion a great deal of Labour for ſeveral Years to extirpate them again. Among theſe are Shepherd's-pouch, Groundſel, Dandelion, Fumitary, Pimpernel, and ſome others. And thoſe of them which do not ſeed ſo early, will (if let ſtand) eſtabliſh themſelves ſo firmly, as to occaſion much Labour to get them out of the Ground: ſo that it is certainly the beſt way to clear all Sorts of Crops from Weeds as ſoon as poſſible in the Spring, and to keep them conſtantly ſo.

In the Beginning of this Month you ſhould ſow Purſlain in the open Ground, and Endive for blanching, and continue to ſow all the Sorts of ſmall Sallet-Herbs every three or four Days, otherwiſe there will not be a Supply of ſuch Herbs which are young; for at this Seaſon they ſoon grow too large for Uſe: But theſe ſhould be ſown in a North Border, where they have little Sun.

Sow Peaſe, and plant Beans for latter Crops; but this ſhould be done on a moiſt Soil, otherwiſe they ſeldom ſucceed well, unleſs the Seaſon is uncommonly wet and cold.

Plant Kidney-Beans for a ſecond Crop; and about the twelfth Day of this Month you ſhould ſow Cauliflowers for Winter Uſe, obſerving to ſhade the Bed with Mats, and keep the Ground moiſt, otherwiſe the Plants will come up very ſparingly.

In moiſt Weather plant out Cabbages and Savoys for Winter Uſe, and tranſplant Celery into Drills for Blanching, which will come early, if planted in this Month.

The Crops of Spinach and Radiſhes being now gone, the Weeds ſhould be clear'd from the Cauliflower and Cabbage-Plants, or Beans which were planted on the ſame Ground; and in moiſt Weather draw ſome Earth round the Stems of the Plants, which will keep the Roots moiſt, and prevent the Sun and Wind from drying their Stems, which if permitted, will greatly retard the Growth of the Plants; but in doing of this, great Care ſhould be taken not to raiſe the Earth ſo high about them, as to fall into the Center of the Leaves, which will intirely deſtroy the Cauliflower Plants.

Tranſplant Radiſhes for Seed, placing them in Rows three Feet Diſtance, and two Feet aſunder in the Rows from each other, obſerving to make Choice of ſuch only as have long, ſtrait, well-colour'd Roots, and ſmall Tops, rejecting all ſuch as are forked or ſhort-rooted; for which Reaſon it is, that the moſt curious Gardeners never ſave Seeds from ſuch as remain where they were ſown, becauſe they can't judge of their Roots.

The Cucumbers and Melons which are under Frames, muſt be carefully ſhaded with Mats in the Heat of the Day, for the Sun is too violent at this Seaſon for them thro' Glaſſes; nor will they endure the open Air, to which many Perſons do often expoſe them; for being brought up tenderly, their Vines do harden and dry, when expoſed to the full Sun. But ſuch Plants as have been rais'd under Hand-glaſſes for the ſecond Crop, ſhould have full Liberty to grow, by raiſing the Glaſſes upon three Bricks or forked Sticks, and the End of the Plants laid out from under the Glaſſes; but this muſt not be done too ſoon, eſpecially if the Nights are cold, which if it ſhould ſo happen after the Plants are laid out, they muſt be covered with Mats every Night, to prevent their being nipp'd by the Cold.

The early Cauliflowers will now begin to appear in the Center of the Plants, therefore they ſhould be carefully look'd over every Day, breaking down ſome of the inner Leaves of ſuch as appear in Flower (as it is uſually term'd) to preſerve them white; for if they are expos'd to the Sun and Air, they will change yellow in a ſhort Time.

Hough Winter Crops of Onions, Carrots, Leeks, Parſnips and Beets, to clear them from Weeds; for by ſtirring of the Ground, the Plants are greatly forwarded in their Growth: keeping ſuch Crops clear from Weeds in this Month, will be of great Service to them, and ſave much Labour the ſucceeding Months.

Tranſplant Sileſia, Imperial, Cos and Brown Dutch Lettuces into North Borders, to ſucceed thoſe planted the laſt Month; and toward the End of the Month you may ſow ſome Brown Dutch and common Cabbage-Lettuces to ſupply the Table in *Auguſt* and *September*: But this muſt be in an open Situation; and if they are not tranſplanted, but ſowed thin, and the Plants houghed out to a proper Diſtance, they will do the better.

Sow Finochia in Drills about eighteen Inches or two Feet aſunder, to ſucceed that which was ſown the laſt Month, and draw the Earth up to the Plants which are almoſt full grown, to blanch them. *N. B.* This ſhould have a light, rich, moiſt Soil, when ſown at this Seaſon, otherwiſe it is apt to run to Seed.

You may yet plant Slips of Sage, Roſemary, Hyſſop, Lavender, Marum, Maſtick, and moſt other Aromatick Plants, obſerving to ſhade and water them until they have taken Root; but it is better to plant them juſt before they ſhoot, becauſe thoſe Shoots which have been produced the ſame Seaſon, are tender, and ſeldom take ſo well.

The early Cabbages do now begin to turn their inner Leaves for Cabbaging, which may be forwarded by tying their Leaves together, either with a withy or Baſs-mat, as is practis'd by the Gardeners near *London*.

Look over your Artichokes again in this Month, and pull up all the Plants from the Roots which have been produced ſince the Stocks were ſlip'd; for theſe will draw the Nouriſhment from the Plants intended for Fruit, and cauſe them to be ſmall. You ſhould alſo cut off all the ſmall Artichokes which are produced from the Side of the Stems of the Artichokes; for if theſe are permitted to grow, they will render the Artichokes on the Top very ſmall. Theſe the Gardeners term Suckers.

Sow Turneps, when there is a Proſpect of Rain in a ſhort Time, which will bring up the Plants very ſoon; and hough thoſe Turneps which were ſown the laſt Month, leaving them about eight or ten Inches aſunder, which will be ſufficient for theſe which are intended to be drawn very young.

Toward the Latter-end of the Month ſhould be ſown Broccoli for Spring Uſe, and a latter Crop of Kidney-Beans ſhould be planted, to ſucceed thoſe before directed, which will become too old by the Time theſe are fit to gather.

Sow Cucumbers in the open Ground, to produce ſome Fruit for pickling, and plant out Gourds and Pumpkins upon Dunghils, *&c.* where they ſhould be allow'd a large Compaſs to ſpread, otherwiſe they will interfere and ſpoil each other.

Products of the KITCHEN-GARDEN.

Radiſhes, Spinach, young Sallet-Herbs, ſeveral Sorts of Cabbage-Lettuce, Sorrel, Mint, Balm, Winter Savory, Borage, Bugloſs, Spring Coleworts, Tragopogon, the young Shoots of which are by ſome preferred to Aſparagus, young Onions, Cives, Aſparagus, Peaſe, Beans, ſome early Artichokes, Cauliflowers, early Cabbages, young Carrots from under Walls or Hedges, Cucumbers, Melons, Purſlain, and Kidney-Beans on Hot-beds, with many other Sorts of Spring-Herbs.

Work to be done in the FRUIT GARDEN.

In the Beginning of this Month you muſt look over your Wall and Eſpalier-trees, and carefully diſplace foreright Shoots, and ſuch as are luxuriant or ill-plac'd, and train ſuch kindly Branches as you would preſerve, regularly to the Wall or Eſpalier, which will prevent your Trees from growing into Confuſion, and ſtrengthen the Fruit-branches, as alſo admit the Sun and Air to the Fruit, which are often obſtructed by the luxuriant Growth of the Branches, to the great Prejudice of the Fruit.

Where Apricocks and Peaches are too thick, they ſhould be thinn'd the Beginning of this Month, obſerving never to leave two or more Fruit together (as is too often practis'd by covetous Perſons): Tho' there be but a ſmall Crop on the Trees, this will make thoſe which are left on much larger and better flavour'd, and render the Trees ſtronger for ſucceeding Years; whereas when they are over-charg'd with Fruit, they are often ſo much weaken'd, as not to be recoverable in three or four Years, notwithſtanding they may be under the moſt ſkilful Management: Beſides, one Dozen of fair well-flavour'd Fruit is preferable to five or ſix Dozen of ſmall ill-nouriſh'd Fruit, and will ſell for more Money in the Markets. The Diſtance which ſhould be allow'd to all Sorts of Fruit, muſt be proportionable to their uſual Sizes; for Inſtance, for middling or ſmall Peaches and Nectarines, five or ſix Inches aſunder is ſufficient; but for the large Sorts eight Inches is full near enough. This muſt alſo be proportion'd to the Strength of the Trees; for weak Trees ſhould have a leſs Number of Fruit left on them than thoſe which are ſtrong, becauſe they are more capable of nouriſhing them.

You muſt now look carefully over your Vines, and ſtop ſuch Shoots as have Fruit on them at the ſecond or third Joint beyond the Fruit, and train the Branches cloſe to the Wall in a regular Order; but ſuch Shoots as are deſign'd for bearing the ſucceeding Year, ſhould not be ſtopp'd until the next Month. You ſhould now rub off all trailing Branches cloſe to the Places where they are produc'd; for if theſe are ſuffer'd to remain, it will occaſion a great Confuſion of Branches, and weaken the bearing Shoots. If this be duly obſerved, there will never be any Neceſſity for diveſting the Shoots of their Leaves to let the Air and Sun to the Fruit, as is by ſome unſkilful Perſons too much practis'd, to the Injury of the Fruit and Branches.

In moiſt Weather you muſt carefully look after Snails, eſpecially in the Evenings and Mornings, or after warm Showers, when they will come from behind Wall-trees, and out of their Places of Shelter, ſo may be eaſily taken; for theſe are great Enemies to choice Fruits.

If the Seaſon ſhould prove dry, you muſt not forget to refreſh all ſuch Trees, as have been lately planted, with Water; in doing of which it will be proper to ſprinkle the Water over all their Branches, which will be of great Service to them in waſhing off Duſt and Filth, which their Leaves may have contracted, and open the Pores of the Shoots, which in very dry Weather are many Times almoſt cloſ'd, whereby the Trees ſuffer greatly; nor is the Water, when poured to the Root only, capable of relieving them when in this Condition; and this is what renders Rain much more effectual than artificial Watering.

Keep the Borders about Fruit-trees clear from Weeds, and all ſtrong growing Plant, which will exhauſt the Goodneſs of of the Soil, to the great Prejudice of your Trees; and this ſhould alſo be carefully obſerv'd in the Nurſery for the ſame Reaſon.

About the Middle of this Month you muſt look over your Vineyard Grapes, diſplacing all dangling Shoots, and ſtopping thoſe which have Fruit upon them, which muſt be faſten'd to the Stakes, to prevent their being broken by Winds; but the Shoots for the next Year's Bearing muſt be train'd up to the Stakes, and not ſtopp'd until the next Month.

You muſt alſo obſerve to keep the Ground in the Vineyard very clear from Weeds, and ſuffer no Sorts of Plants whatever to grow between the Rows of Vines; for nothing can be more prejudicial than permitting this in Vineyards.

Toward the latter End of the Month you ſhould break off the Clay from thoſe Trees which were grafted in the Spring, and looſen their Bandage, otherwiſe they are ſubject to break off where they are pinch'd with the Baſs.

Fruits in prime, or yet laſting.

Pears; L'Amozelle, or Lord Cheney's Green, Bergamot de Paque, Bezy du Chaumontelle, Parkinſon's Warden, and ſometimes the Cadillac.

Apples; Golden Ruſſet, Stone Pippen, John Apple, Winter Ruſſet, Pomme d'Api, Oaken Pin, Pile's Ruſſet, and ſometimes the Nonpareil and Golden Pippen.

Cherries; the May and May Duke; and in a warm Soil, ſome ſcarlet Strawberries, Gooſeberries and Currants for Tarts; and in the Forcing-frame, Maſculine Apricocks, Nutmeg Peaches, with ſome other early Fruits.

Work to be done in the NURSERY.

In this Month you muſt carefully keep the Ground houghed between your young Trees; for nothing is more injurious to them, than to ſuffer Weeds, or any other Plants, to grow amongſt them; for theſe rob the Trees of their Nouriſhment; and if Weeds are permitted to get Strength in this Month, it will be great Trouble to root them out afterwards.

The Middle of this Month you muſt look over your Grafts, and take off the Loam from them; and thoſe which were faſtened with Bandage, ſhould now be untied, otherwiſe the Graft will be pinched at the Stock, and be in Danger of breaking off with the Wind. You ſhould alſo look over your Trees, which were budded the laſt Seaſon; and where you obſerve the Leaves to curl up by being infeſted with Inſects, you ſhould take them off otherwiſe they will ſpoil the upright Shoot.

Your Seed-beds muſt now be carefully weeded, and in dry Weather frequently refreſh'd with Water, otherwiſe the young Plants will be ſo ſtunted, as not to make any Progreſs the ſame Seaſon. Your young Plants of Cedars, Firs, Pines, *&c.* muſt now be often refreſh'd with Water, but it ſhould not be given to them in large Quantities, but rather often and moderate. You muſt alſo obſerve to ſhade them from the Sun, to which if they are too much expoſed while young, it is often very deſtructive to them.

You may now make Layers of the Double and Single Virgins Bower, and of other climbing Plants; for many of theſe will not root from the woody Shoots; but the tender Branches of the ſame Year's Growth, if layed in this Month, will take Root very well. You may alſo lay down Alaternus's, Phillyrea's, and ſome other evergreen Trees, which do alſo take Root better from young Shoots, than from older Branches.

If this Month ſhould prove very dry, you muſt continue to water ſuch Evergreens, and other young Trees, as were removed the laſt Seaſon, otherwiſe the will ſuffer greatly. You ſhould alſo renew the Mulch round the Trees, to prevent the Sun and Wind from drying the Ground.

Work to be done in the FLOWER GARDEN.

The Beginning of this Mouth you ſhould take up your choice Hyacinth-roots, which are paſt flowering, and lay them horizontally in a Bed of Earth to ripen, leaving their Leaves and Stems out of the Ground to decay, in the Manner directed under the Article *Hyacinth*.

Shade your choice Tulips, Ranunculus's, Anemonies, and other curious Flowers now blowing, from the Sun during the Heat of the Day, which will continue them in Beauty much longer than if they are fully expos'd to the Weather.

Take up the Roots of the Saffron, whoſe Leaves are by this Time decay'd, and ſpread them on Mats in the Shade to dry; after which they may be kept in Bags until *July*, when it will be a proper Seaſon for planting them up.

Clean the Borders of your Flower-Garden from Weeds, which, if permitted to grow at this Seaſon, will be the more difficult, and cauſe a deal of Trouble to extirpate afterwards.

About the Middle of this Month you may plant out your hardy Annuals, ſuch as Marvel of Peru, Sweet Sultan, French and African Marygolds, Female Balſamine, Capſicum, Brown Jolly, and ſeveral other Sorts, which, if artfully diſpos'd, will afford an agreeable Pleaſure, after the Beauty of the Spring is paſt.

Sow Dwarf Annual Flower-Seeds in Patches upon the Borders of the Flower-Garden, where they are intended to remain, as Candy-Tuft, Venus-Looking-glaſs, Venus-Navelwort, Dwarf Annual Stock, Dwarf Lychnis, Lobel's Catchfly, Convolvulus Minor, with many other Kinds; as alſo plant the ſeveral Kinds of Lupine, Sweet-ſcented Peaſe, Tangier Peaſe, Seeds of the Indian Naſturtium, Large Convolvulus, and other climbing Annual Plants, where they may have room to ſpread, and have ſome Support, in which Places they will flower, and make a beautiful Appearance.

Tranſplant ſuch Biennial and Perennial Flowers, as were ſown in the Flower-Nurſery in *March* and *April*, into Beds of freſh Earth in the Nurſery, where they may remain till the latter End of *Auguſt*, or the Beginning of *September*, when they muſt be remov'd into the Borders of the Flower-Garden: Of theſe Sorts are Canterbury-Bells, French Honeyſuckles, Sweet-Williams, Pinks, Columbines, with many others.

Tie up the Spindles of Carnations, diveſting them of all ſide *Pods*, which, if permitted to remain on, would weaken the *Top* and principal Flower: And alſo ſtick and faſten the Stems of all tall Flowers which are to blow, otherwiſe they will be in danger of being broken by the Winds.

Make a freſh Hot-bed for your Amaranthus's, Double-ſtrip'd Balſamine, and other tender exotick Annuals, and put them into large Pots of good Earth, placing them upon the Hot-bed, and fill up the Interſtices with Earth; if Care be taken of them at this Time, they will be very ſtrong and beautiful.

Your Auricula's, which are now paſt flowering, ſhould be remov'd into a ſhady Situation (but not under the Droppings of Trees, which will rot them); in which Place they muſt remain, until the Heat of Summer is over.

Tranſplant Stock-Gilliflowers, Wall-flowers, ſeedling Pinks, Carnations, and other perennial ſeedling Flowers; and ſow ſome Seeds of Annual, ſcarlet, and purple Stock-Gilliflowers, which will produce ſhorter Plants, and many Times will endure the Cold better than thoſe which are larger.

Toward the latter End of the Month you may take up early Tulip-roots, and ſome of the forward Anemonies, if their Leaves are decay'd, after which they ſhould not be permitted to remain in the Ground.

Plant ſome Tuberoſe-roots upon a moderate Hot-bed, to ſucceed thoſe planted in *March* and *April*, by which Method you may continue a Succeſſion of this fragrant Flower until *October* in Beauty.

Your Pots of ſeedling Iris's and other bulbous rooted Flowers, ſhould be now remov'd into a ſhady Situation (if it was not done in *April*) where they muſt remain until Autumn, nothing being more injurious to theſe young Roots, than to be expos'd to the Violence of the Sun in Summer, eſpecially if they are in Tubs or Pots.

The young Plants of Venice Mallow, Oriental Mallow, and Lavatera's, may now be planted into the Beds or Borders of the Flower-Garden, where they will make a beautiful Appearance when they flower. But this Work ſhould be done in moiſt Weather.

Place your Pots of choice Carnations upon the Stage to protect them from Vermin, which will otherwiſe infeſt them, and will harbour about the Pots, ſo as not to be eaſily deſtroy'd.

Plants now in Flower.

Late Blowing Tulips, Anemonies, Ranunculus's, Pinks of ſeveral Sorts, white and yellow Aſphodel, Lily of the Valley, Daizies, Leucanthemums, Thrift, red and white Valerian, Cyanus Major, Thalictrums of ſeveral Kinds, Sage, Roſemary, Moth Mullein, Double Catchfly, Veronica multicaulis Pannonica, London-pride, Spaniſh Figwort, Geraniums of ſeveral Kinds, Helianthemums, Turkey perennial Poppy, Fiery Lily, Peonies of ſeveral Sorts, Columbines, Monkſhood, Fraxinella red and white, yellow Moly, Homer's Moly, Stock-Gilliflowers, Wall-flowers, Orobus viciæ foliis, Tragacantha, Leopard's-bane, Solomon's-ſeal, yellow Aſphodel Lily, Hyacinth of Peru, Dragon, Biſtort, Rhapontick, Lady's Mantle, Tuberoſe Iris's, Dwarf Annual Stock, Feather'd Hyacinth, Lady's Slipper, Welſh Poppy, Bird's-eye, yellow Violet, Orchis's, Heart's-eaſe, Double white Narciſſus, Pulſatilla, Double Rockets, Corn-Flags, Engliſh Hyacinth or Hare-bells, yellow and Pompony Martagons, Starry Hyacinth, Blue Grape Hyacinth, bulbous Iris, Tradeſcant's Spiderwort, Savoy Spiderwort, Double purple and large blue Periwinkles, Peach-leav'd and Nettle-leav'd Bell-flower, Hedyſarum Clypeatum flore albo & rubro, Lychnidea Virginiana, Greek Valerian white and blue, Double white and red Batchelor's Button, Double white Mountain Ranunculus, Double Ragged Robin, Double Feverfew, Fox-Glove three Sorts, Buphthalmums, Sea-Ragwort, Sea-Holly, Double Saxifrage, Double Ladies Smock, Borage-leav'd Auricula, Spaniſh Toadflax, Spurges of ſeveral Kinds, Graſs-leav'd Ranunculus, Honeſty or ſatten Flower, Upright Speedwell, yellow Eaſtern Bugloſs, Garden Bugloſs, Onobrychis, Scabious's, Bird's-eye, with ſome others of leſs Note.

Hardy Trees and Shrubs now in Flower.

Phlomis, or Jeruſalem Sage, two or three Sorts, yellow Jaſmine, Colutea Scorpioides, Oriental Colutea with bloody Flowers, Lilacs ſeveral Sorts, Early White, Italian, and Common Honeyſuckles, Gelder Roſe, White Thorn, Flowering Aſh, Bladder-Nut, Cinnamon Roſe, Monthly Roſe, Damask Roſe, Burnet-leav'd Roſe, Scotch Roſe, Apple-bearing Roſe, Horſe Cheſnut, Three-Thorn'd Acacia, Laburnus, Cytiſſus ſecundus Cluſii *vulgo*, Lote or Nettle-tree, Bladder Senna, Double flowering Almond, Cockſpur Hawthorn, Double flowering Hawthorn, Cinquefoil Shrub, Perſian Lilac, Bird Cherry, Corniſh Cherry, Lauro-Ceraſus, Scarlet Horſe-Cheſnut, Perfumed Cherry, Male-Ciſtus, Mallow-Tree, Arbor Judæ, Cytiſſus Lunatus, Sea Buckthorn, Spirea Salicis folio, Spirea Opuli folio, Spirea Hyperici folio, Dwarf Medlar, Amelanchier, Wild Service or Quickbeam, Aria Theophraſti, Double-flowering Cherry, Stœchas purpurea, with ſome others.

Work to be done in the GREEN-HOUSE, *and* STOVE.

Towards the Middle of this Month, if the Weather be ſettled, and the Nights warm, you ſhould bring forth your Orange-trees, and (if poſſible) take the Advantage of a Shower of Rain for this Work, which will waſh the Duſt from the Surfaces of their Leaves, and greatly refreſh them; you ſhould at this Time (if you have not before done it) take out the Earth from the Top of the Pots or Tubs, and fill them up with freſh rich Earth, which will greatly encourage their Flowering, and cauſe them to make vigorous Shoots; and if their Stems have not been cleans'd the precedent Month, it ſhould be now done; but this is only meant for ſuch Trees as are not remov'd the ſame Year.

You may now inarch Oranges, Jaſmines, Pomegranates, and other tender Exotick trees, obſerving to place them where they may be ſhelter'd from ſtrong Winds, which would diſplace the inarch'd Shoots, if they were too much expos'd thereto.

Make Layers of Myrtles, Pomegranates, Jaſmines, Granadilla's, Capers, and other tender Shrubs, obſerving to ſupply them conſtantly with Water, which will greatly facilitate their Rooting.

In the Middle of the Day, if the Weather prove hot, you ſhould ſhade the Glaſſes of the Stove, and the Hot-beds, where your choice Exotick plants are plac'd, and let them have free Air, in Proportion to the Warmth of the Seaſon; and ſuch of your Exotick plants as want ſhifting, ſhould now be remov'd, and ſome of them plac'd in larger Pots, giving them freſh Earth, and then plunge them into the Hot-bed again, obſerving to ſhade the Glaſſes until they have taken freſh Root.

Toward the Latter-end of the Month make Cuttings of Ficoides's, Sedums, Cotyledons, Cereus's, Euphorbiums, and other ſucculent Plants, laying them in a dry ſhady Place, a Week or more before they are planted, that the wounded Part may be heal'd up, otherwiſe they are ſubject to rot; and when they are planted, they ſhould be plac'd (ſuch of them as are hardy) in a ſhady Situation for a Week or more; but thoſe which are tender muſt be planted in Pots, and plung'd into a moderate Hot-bed of Tanners-bark, obſerving to ſhade the Glaſſes in the Heat of the Day, and refreſh them with Water as they may require.

Cleanſe the Leaves of Aloes, and other tender Exotick-plants, from Duſt and Filth, which they have contracted in the Houſe the laſt Winter, and cut off all decay'd Leaves of thoſe Plants, for now the Wounds given to them will ſoon heal: This is alſo a proper Time to cut off the Heads of thoſe Sorts of Aloes which grow with large Stems, and ſeldom afford Off-ſets; ſo that there is no other Method to propagate them, than by taking off their Heads for planting, and thereby cauſing their Stems to ſend forth a freſh Shoot or two; but you muſt obſerve to leave three or four good Leaves upon the Stem to draw the Sap, otherwiſe the Stem will decay without producing any new Head; you muſt alſo keep them in the Houſe, and not expoſe them abroad to the Wet, until the Wounds are perfectly heal'd; and if you plunge them into a moderate Hot-bed, it will facilitate their Shooting.

Bring out all your hardy Exotick Plants, ſuch as Ciſtus's, Geraniums, Alaternoides's, Sorrel-tree, Amber-tree, Anemonoſpermos's, Hermannia's, yellow Indian and Spaniſh Jaſmines, Polygala fruteſcens, Myrto-Ciſtus, Fabago's, Rhus's, with ſeveral other Sorts, which will now bear the open Air; but you ſhould obſerve to place them in a ſhady Situation for a Fortnight; for if they are immediately expos'd to the full Sun, it will change their Leaves to a brown Colour, and cauſe the Plants to appear very unſightly.

Thoſe Exotick Plants which are continu'd in the Houſe, muſt now have a great Share of freſh Air (eſpecially if the Seaſon be warm) otherwiſe they will draw very weak, and change to a pale languid Colour; and if the Glaſſes are ſhaded in the Heat of the Day, it will be better than to expoſe them too much to the Sun. You ſhould alſo obſerve to cleanſe their Leaves and Shoots from Inſects, which are very apt to infeſt them in the Houſe, eſpecially where the Plants are much crowded; and if theſe are not waſh'd off in time, they will greatly injure the Plants, eſpecially the Coffee-tree, which is now near Flowering, and is frequently infeſted with theſe ſmall Vermin, which at firſt appear like Duſt upon the Leaves, which ſhould be immediately waſh'd off, otherwiſe they will ſpread in a ſhort time over moſt Parts of the Plants.

If the Seaſon ſhould prove cool, and the Bark-bed, in which your Anana's are plac'd, ſhould abate of its Heat, you muſt ſtir it up again, and mix a little new Bark with it, which will renew the Heat, and be of great Service in forwarding the Fruit; and at this time you ſhould ſhift thoſe Plants which are to produce Fruit the ſucceeding Year into larger Pots, that their Roots may have room to ſpread.

Plants now flowering in the GREEN-HOUSE, *and* STOVE.

Geraniums ſeveral Sorts, Teucrium Bœoticum, Anemonoſpermos's, Chryſanthemoides atriplicis folio, Leucanthemum, Canarienſe pyrethri ſapore, Hermannia fruteſcens Ibiſci folio, Elichryſums, Cytiſſus Canarienſis, Ciſtus Ladanifera, Jaſminum Ilicis folio, Heliotropium Scorodoniæ folio, Polygala Africana, Arum Æthiopicum flore albo odorato, Convolvulus Canarienſis, Ficoides's ſeveral Sorts, Aloe-leav'd Aſphodel, African-tree Scabious, Salvia Africana fruteſcens flore aureo magno, Ricinoides folio multifido, Ricinoides Staphyſagriæ folio, Lotus Argentea Cretica, Turnera fruteſcens Ulmi folio, Lilio-narciſſus's, Panacratium's, Jujubes, Myrtles, Staphylodendron Africanum, Convolvulus erectus argenteus, Baſſella, Arabian Jaſmine, Indian Fig, Oranges, Lemons, Citorns, Limes, and ſome Sorts of Aloes.

MAYS; Indian Wheat.

The *Characters* are;

The whole Plant has the Appearance of a Reed; the Male Flowers are produc'd at remote Diſtances from the Fruit on the ſame Plant, growing, for the moſt part, in a Spike upon the Top of the Stalk; the Female Flowers are produc'd from the Wings of the Leaves, and are ſurrounded by three or four Leaves, which cloſely adhere to the Fruit until it is ripe.

The *Species* are;

1. MAYS *granis aureis. Tourn.* Common Indian Wheat, with yellow Grains.
2. MAYS *granis albicantibus. Tourn.* Indian Wheat, with white Grains.
3. MAYS *granis rubris. Tourn.* Indian Wheat, with red Grains.
4. MAYS *granis violaceis. Tourn.* Indian Wheat, with Violet-colour'd Grains.
5. MAYS *minor, granis luteis.* Leſſer Indian Wheat, with yellow Grains.
6. MAYS *minor, granis rubris.* Leſſer Indian Wheat, with red Grains.
7. MAYS *minor, granis violaceis.* Leſſer Indian Wheat, with Violet-colour'd Grains.

There are ſome other Varieties in the Colour of the Grains of this Plant, which are chiefly occaſion'd by the interchanging of the *Farina* of one Sort with that of another, whereby the Spikes are often of two or three different Colours, as it commonly happens when the ſeveral Colours are planted in the ſame Spot of Ground.

This Plant is ſeldom propagated in *England* but as a Curioſity in ſome curious Gardens; but in *America* it is one of their greateſt Supports, and is there cultivated with great Care, in the following Manner:

They dig the Ground well in the Spring, and, after having dreſs'd it well, they draw a Line acroſs the whole Width of the Piece intended to be planted; then they raiſe little Hills of Earth at about three Feet Diſtance, into each of which they plant two or three good Seeds, covering them about an Inch thick with Earth; then they move the Line four Feet farther, continuing to do the ſame through the whole Spot of Ground, ſo that the Rows may be four Feet aſunder, and the Hills in the Rows at three Feet Diſtance. Six Quarts of this Seed are generally allow'd to an Acre of Ground, which, if the Soil be good, will commonly produce fifty Buſhels of Corn.

If, in the planting of this Corn, you obſerve to put the Grains of any one Colour in a Field by itſelf, and no other colour'd Grain ſtand near it, it will produce all of the ſame Colour again, (as hath been affirm'd by ſeveral curious Perſons in that Country): but if you plant them in Rows of the different Colours alternately, they will interchange, and produce a Mixture of all the Sorts in the ſame Row, and frequently on one and the ſame Spike. Nay, it is affirm'd, that they will mix with each other at the Diſtance of three or four Rods, provided there be no tall Fence or Building between to intercept 'em.

There is nothing more obſerv'd in the Culture of this Plant, but only to keep it clean from Weeds, by frequent houghing the Ground, and, when the Stems are advanc'd, to draw the Earth up in a Hill about each Plant; which, if done after a Shower of Rain, will greatly ſtrengthen them, and preſerve the Ground about their Roots moiſt a long time.

When the Corn is ripe, they cut off the Stems cloſe to the Ground; and after having gather'd off the Spikes of Corn, they ſpread the Stalks to harden and dry, which they afterwards uſe for covering of Sheds, *&c.* for which Purpoſe it is very uſeful to the Inhabitants of the warm Parts of *America*, as alſo for feeding their Cattle, while green, which is what they often uſe, when other Fodder is ſcarce.

But notwithſtanding this Plant at preſent is only cultivated as a Curioſity in *England*, yet it is probable it might be propagated with good Succeſs, and become a Piece of Good-huſbandry in ſuch Places where *Beans* will not ſucceed, as particularly in light ſandy Lands, (where the Inhabitants are at a great Loſs for hearty Fodder for their Cattle) upon which this Plant will ſucceed extremely well, and ſupply the Want of *Beans*, perhaps better than any other Plant. The ſmall Sort is what I would recommend to be ſown in *England*, which is what the Inhabitants of *North-America* cultivate; and this will perfect its Seeds in leſs than four Months from ſowing, as I have ſeveral times proved; and even in ſome of the moſt unfavourable Years, it has ripen'd in full four Months from ſowing.

In cultivating this Plant, the Ground ſhould be well plough'd and dreſs'd, and the Rows of Corn placed four or five Feet aſunder, and about two Feet aſunder in the Rows; ſo that with a ſmall Breaſt-Plough the Ground may be often ſtirr'd, whereby the Weeds will be intirely deſtroy'd; which if duly obſerv'd while the Plants are young, there will be no occaſion to repeat it, after they are up to a Height; for then the Plants will prevent the Growth of Weeds, by overſhadowing the whole Ground.

The beſt Time to plant theſe Seeds is in the Beginning of *April*, when the Weather is ſettled; for if it be ſown too ſoon, the cold Nights and wet Weather often deſtroy the Seeds; and if it be ſown too late, and the Autumn ſhould prove bad, it would not ripen well.

The large Sort, when cultivated as a Curioſity, ſhould be ſown upon a moderate Hot-bed in the Beginning of *March*; and in the Middle of *April* they ſhould be carefully tranſplanted where they are to remain; and if the Seaſon proves favourable, the Seeds will ripen very well; but without being thus early rais'd, this Sort ſeldom comes to much in this Country.

MEADOW SAFFRON. *Vide* Colchicum.

MEDICA; [This Plant takes its Name from *Media*, (as *Pliny* writes); becauſe that when *Darius Hyſtaſpis* carry'd his Army into *Greece*, he had with him a great many Sacks of this Seed for Provender for his Cattle, and ſo the Seeds came to be ſcatter'd in *Greece*. This Plant is much cultivated in *France*, and there it is call'd *Burgundian Hay*: It is more filling and nutritious than double the Quantity of *Graſs*; and the Herds, by that means, become very plethorick, ſo that they require Blood-letting the oftner] Medick, *or* La Lucerne.

The *Characters* are;

It hath a papilionaceous (or Butterfly) Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes an intorted Pod ſomewhat like a Ram's Horn, in which are lodg'd Kidney-ſhap'd Seeds.

The *Species* are;

1. MEDICA *major erectior, floribus purpuraſcentibus. J. B.* Greater Upright Medick, *or* La Lucerne, with purpliſh Flowers.
2. MEDICA *major erectior, floribus violaceis. Tourn.* Greater Upright Medick, *or* La Lucerne, with Violet-colour'd Flowers.
3. MEDICA *major erectior, floribus luteis. Tourn.* Greater Upright Medick, *or* La Lucerne, with yellow Flowers.
4. MEDICA *major erectior, floribus ex violaceo & luteo mixtis. Tourn.* Greater Upright Medick, *or* La Lucerne, with Violet and Yellow Flowers mix'd.

Theſe Plants do not greatly differ from each other but in the Colour of their Flowers; tho' I think that with the Violet-colour'd Flower produces the largeſt Leaves, and ſtrongeſt Shoots; and that with the yellow Flowers, the ſmalleſt Leaves, and weakeſt Shoots: ſo that the Violet-colour'd Flowering is the beſt Sort to cultivate for Fodder.

This Plant is ſuppos'd to have been brought originally from *Media*, and from thence had its Name *Medica*: It is by the *Spaniards* call'd *Alfaſa*; by the *French*, *La Lucerne*, and *Grande Trefle*; and by ſeveral Botanick Writers it is call'd *Fœnum Burgundiacum*, i. e. *Burgundian Hay*. But there is little Room to doubt of this being the *Medica* of *Virgil*, *Columella*, *Palladius*, and other ancient Writers of Husbandry, who have not been wanting to extol the Goodneſs of this Fodder, and have given Direction for the Cultivation of it in thoſe Countries where they liv'd.

But notwithſtanding it was ſo much commended by the Ancients, and hath been cultivated to ſo good Purpoſe by our Neighbours in *France* and *Switzerland* for many Years, it hath not as yet found Reception in our Country, in any conſiderable Quantity: Tho' it is evident, it will ſucceed as well in *England* as in either of the before-mention'd Countries, being extreme hardy, and reſiſting the ſevereſt Cold of our Climate: Nay, I have had the Seeds which have happen'd to be ſcatter'd upon the Ground in Autumn, come up and endure the Cold of a ſevere Winter, and make very ſtrong Plants.

About the the Year 1650, the Seeds thereof were brought over from *France*, and ſown in *England*: but whether for want of Skill in its Culture, whereby it did not ſucceed, or that the People were ſo fond of going on in their old beaten Road, as not to try the Experiment, whether it would ſucced here, or not, was the Occaſion of its being intirely neglected in *England*, I cannot ſay. However, I hope, before I quit this Article, to give ſuch Directions for its Culture, as will encourage the People of *England*, to make farther Trial of this valuable Plant, which grows in the greateſt Heat, and alſo in very cold Countries, with this difference only, that in very hot Countries, ſuch as the *Spaniſh Weſt-Indies*, *&c.* where it is the chief Fodder for their Cattle at this Time, they cut it every Month, whereas in cold Countries it is ſeldom cut oftner than two or three times a Year. And it is very likely that this Plant will be of great Service to the Inhabitants of *Barbados*, *Jamaica*, and the other hot Iſlands in the *Weſt-Indies*, where one of the greateſt Things they want is Fodder for their Cattle; ſince, by the Account given of this Plant by *Pere Fuilleé* it thrives exceedingly in the *Spaniſh Weſt-Indies*, particularly about *Lima*, where they cut it every Week, and bring it into the Market to ſell, and is there the only Fodder cultivated.

It is alſo very common in *Languedoc*, *Provence*, and *Dauphiné*, and all over the Banks of the *Rhone*, where it produces abundantly, and may be mowed five or ſix times in a Year. *Horſes*, *Mules*, *Oxen*, and other domeſtick *Cattle* love it exceedingly, but above all when it is green, if they are permitted to feed on it, and eſpecially the Black Cattle, which will feed very kindly upon the dry'd Plant; the Exceſs of which is by many People thought to be very dangerous: But it is ſaid to be exceeding good for Milch Cattle, to promote their Quantity of Milk; and is alſo ſaid to agree with Horſes the beſt of all, tho' Sheep, Goats, and moſt other Cattle will feed upon it.

The Directions given by all thoſe who have wrote of this Plant, are very imperfect, and, generally, ſuch as if practis'd in this Country, will be found intirely wrong; for moſt of them order the mixing of this Seed with *Oats* or *Barley*, (as is practis'd for *Clover*); but in this Way it ſeldom comes up well, and if it does, it will draw up ſo weak by growing amongſt the Corn, as not to be recover'd under a whole Year, if ever it can be brought to its uſual Strength again.

Others have directed it to be ſown upon a low, rich, moiſt Soil, which is found to be the worſt next to a Clay of any for this Plant; in both which the Root will rot in Winter, and in a Year or two the whole Crop will be deſtroy'd.

But the Soil in which this Plant is found to ſucceed beſt in this Country, is a light, dry, looſe, ſandy Land, which ſhould be well plough'd and dreſs'd, and the Roots of all noxious Weeds, ſuch as *Couch-graſs*, &c. deſtroy'd, otherwiſe theſe will overgrow the Plants while young, and prevent their Progreſs.

The beſt time to ſow the Seed is about the Beginning of *April*, when the Weather is ſettled and fair; for if you ſow it when the Ground is very wet, or in a rainy Seaſon, the Seeds will burſt and come to nothing, (as is often the Caſe with ſeveral of the Leguminous Plants); therefore you ſhould always obſerve to ſow it in a dry Seaſon; and if there happens ſome Rain in about a Week or ten Days after it is ſown, the Plants will ſoon appear above-ground.

But the Method I would direct for the ſowing theſe Seeds, is as follows: After having harrow'd the Ground very fine, you ſhould make a Drill quite acroſs the Ground about half an Inch deep, into which the Seeds ſhould be ſcatter'd very thin; then cover them over about half an Inch thick, or ſomewhat more, with the Earth; then proceed to make another Drill about two Feet from the former, ſowing the Seeds therein in the ſame Manner as before, and ſo proceed through the whole Spot of Ground, allowing two Feet Diſtance between Row and Row, and ſcatter the Seeds very thin in the Drills. In this Manner an Acre of Land will require about ſix Pounds of Seeds; for when it is ſown thicker, if the Seed grows well, the Plants will be ſo cloſe as to ſpoil each other in a Year or two, the Heads of them growing to a conſiderable Size, as will alſo the Roots, provided they have Room. I have meaſur'd the Crown of one Root, which was in my Poſſeſſion, eighteen Inches Diameter, from which I cut near four hundred Shoots at one time, which is an extraordinary Increaſe, and this upon a poor, dry, gravelly Soil, which had not been dung'd for many Years, but the Root was at leaſt ten Years old; ſo that if this Crop be well cultivated, it will continue many Years, and be equally as good as when it was firſt ſown; for the Roots do generally run down very deep in the Ground, provided the Soil be dry; and although they ſhould meet a hard Gravel, a Foot below the Surface, yet their Roots would penetrate it, and make their Way downward, as I have experienc'd, having taken up ſome of them which were above a Yard in Length, and had run above two Feet into a Rock of Gravel, which was ſo hard as not to be looſen'd without Mattocks, and Crows of Iron, and that with much Difficulty.

The Reaſon for directing this Seed to be ſown in Rows, is that the Plants may have Room to grow; and for the better ſtirring the Ground between them, to deſtroy the Weeds, and encourage the Growth of the Plants, which may be very eaſily effected with a ſmall Breaſt-Plough, juſt after the cutting the Crop each time, which will cauſe them to ſhoot again in a very little Time, and be much ſtronger than in ſuch Places where the Ground cannot be ſtirred: but you can't pretend to to uſe a Plough the firſt Seaſon amongſt it, until the Plants have taken good Root in the Ground; therefore when they firſt come up, the Ground between ſhould be hough'd: And if in doing of this you cut up the Plants where they are too thick, it will cauſe the remaining to be much ſtronger. This Houghing, ſhould be repeated two or three times while the Plants are young, according as the Weeds are produc'd, obſerving always to do it in dry Weather, that the Weeds may the better be deſtroy'd; for if it be done in moiſt Weather, they will root and grow again.

With this Management, the Plants will grow to the Height of two Feet or more by the Beginning of *Auguſt*, when the Flowers will begin to appear; at which Time it ſhould be cut, obſerving to do it in a dry Seaſon, and keep it often turn'd, that it may ſoon dry, and be carry'd off the Ground; for if it lie long upon their Roots, it will prevent their ſhooting again: After the Crop is taken off, you ſhould ſtir the Ground between the Rows with a Breaſt-plough, to kill the Weeds, and looſen the Surface, which will cauſe the Plants to ſhoot again in a ſhort Time, ſo that by the Beginning of *September*, there will be Shoots four or five Inches high; when you may turn in Sheep upon it to feed it down, for it will not be fit to cut again the ſame Seaſon, nor ſhould the Shoots be ſuffer'd to remain upon the Plants, which would decay when the froſty Weather comes on, and fall down upon the Crown of the Roots, and prevent their ſhooting early the ſucceeding Spring.

So that the beſt Way is to feed it until *November*, when it will have done ſhooting for that Seaſon: But it ſhould not be fed by large Cattle the firſt Year, becauſe the Roots being young would be in Danger of being deſtroy'd either by their trampling upon them, or their pulling them out of the Ground: But Sheep will be of Service to the Roots by dunging the Ground, and they will not eat it too cloſe, ſo as to endanger the Crown of the Roots.

The Beginning of *February*, the Ground between the Roots ſhould be again ſtirred with the Plough, to encourage them to ſhoot again; but in doing of this, you ſhould be careful not to injure the Crown of the Roots, upon which the Buds are at that Time very turgid, and ready to puſh. With this Management, (if the Soil be warm) by the Beginning of *March* the Shoots will be five or ſix Inches high; when, if you are in want of Fodder, you may feed it down till a Week in *April*: After which it ſhould be ſuffer'd to grow for a Crop, which will be fit to cut the Beginning of *June*; when you ſhould obſerve to get it off the Ground as ſoon as poſſible, and ſtir the Ground again with the Plough, which will forward the Plants ſhooting again, ſo that by the Middle or Latter-end of *July* there will be another Crop fit to cut, which muſt be managed as before: After which it ſhould be fed down again in Autumn, and as the Roots by this Time will have taken deep Hold in the Ground, ſo there will be little Danger of hurting them, if you ſhould turn in larger Cattle; but you muſt always obſerve not to ſuffer them to remain after the Roots have done ſhooting, leſt they ſhould eat down the Crown of the Roots below the Buds, which would conſiderably damage, if not deſtroy them.

In this Manner you may continue conſtantly to have two Crops to cut, and two Feedings upon this Plant; and in good Seaſons there may be three Crops cut, and two Feedings, which will be a great Improvement, eſpecially as this Plant will grow upon dry barren Soils, where Graſs will come to little, and be of great Uſe in dry Summers when Graſs is often burnt up. And as it is an early Plant in the Spring, ſo it will be of great Service when Fodder falls ſhort at that Seaſon; when it will be fit to feed, at leaſt a Month before Graſs or Clover; for I have had this Plant eight Inches high by the tenth of *March*, at which Time the Graſs in the ſame Place has ſcarcely been one Inch high.

That the Cold will not injure this Plant, I am fully ſatisfy'd; for in the very cold Winter *Anno* 172$\frac{8}{9}$, I had ſome Roots of this Plant which were dug up in *October*, and laid upon the Ground in the open Air till the Beginning of *March*; when I planted them again, and they ſhot out very vigorouſly ſoon after; nay even while they lay upon the Ground, they ſtruck out Fibres from the Underſide of the Roots, and had begun to ſhoot green from the Crown of the Roots. But that Wet will deſtroy the Roots, I am fully convinc'd; for I ſow'd a little of the Seed upon a moiſt Spot of Ground for a Trial, which came up very well, and flouriſh'd exceedingly during the Summer-ſeaſon; but in Winter, when the great Rains fell, the Roots began to rot at Bottom, and before the Spring, were moſt of them deſtroy'd.

The beſt Places to procure the Seed from, are *Switzerland*, and the Northern Parts of *France*, which ſucceed better with us than that which comes from a more Southern Climate: But this Seed may be ſav'd in *England* in great Plenty; in order to which, a ſmall Quantity of the Plants ſhould be ſuffer'd to grow uncut till the Seeds are ripe; when it muſt be cut, and laid to dry in an open Barn where the Air may freely paſs through: But the Seed muſt be defended from the Wet; for if it be expos'd thereto, it will ſhoot while it remains in the Pod, whereby it will be ſpoil'd: When it is quite dry, it muſt be threſh'd out and cleans'd from the Huſk, and preſerv'd in a dry Place till the Seaſon for ſowing it: And this Seed ſav'd in *England* is much preferable to any brought from Abroad, as I have ſeveral times experienc'd; the Plants produc'd from it having been much ſtronger than thoſe produc'd from *French*, *Helvetian*, or *Turkey* Seeds, which were ſown at the ſame Time, and on the ſame Soil and Situation.

I am inclinable to think, that the Reaſon of this Plant not ſucceeding, when it has been ſown in *England*, has either been occaſion'd by the ſowing it with Corn, with which it will by do means thrive (for tho' the Plant be very hardy when grown pretty large, yet at its firſt coming up, if it be incommoded by any other Plants or Weeds, it ſeldom does well; therefore it ſhould always be ſown by itſelf, and carefully clear'd from Weeds until it has Strength, after which it is not eaſily deſtroy'd): Or perhaps People have ſown it at a wrong Seaſon, or in wet Weather, whereby the Seeds have rotted and never come up, which has diſcourag'd their attempting it again: But however the Succeſs has been, I dare aver, that if the Method of ſowing and managing of this Plant, which is here laid down, be duly follow'd, it will be found to thrive as well as any other Sort of Fodder now cultivated in *England*, and will continue much longer; for if the Ground be duly ſtirred between each Crop, and the laſt Crop fed, as hath been directed, the Plants will continue in Vigour twenty Years or more without renewing, provided they are not permitted to ſeed, which would weaken the Roots more than four times cutting it would do.

The Hay of this Plant ſhould be kept in cloſe Barns, it being too tender to be kept in Reeks open to the Air as other Hay; but it will remain good, if well dry'd before it be carry'd in, three Years. The People abroad reckon an Acre of this Plant ſufficient to keep three Horſes all the Year round.

MEDICA COCHLEATA; Snail-Trefoil.

The *Characters* are;

Theſe Plants differ from the former in the Fruit, which of theſe Kinds are ſhap'd like a Snail.

There are great Numbers of Sorts of this Plant, which are preſerv'd in Botanick Gardens for Variety; but I ſhall in this Place only mention two or three of the moſt curious Sorts, which are cultivated in Gardens for the Oddneſs of their Fruit.

The *Species* are;

1. MEDICA *ſcutellata. J. B.* The Snail-Trefoil, *commonly call'd in the Seed-ſhops* Snails.
2. MEDICA *orbiculata. J. B.* Flat, round Snail-Trefoil.
3. MEDICA *cochleata ſpinoſa, echinis magnis, utrinque turbinatis, cum ſpinulis reflexis. Raii Hiſt.* Prickly cochleated *Medick*, with a large Head turbinated on every Side with reflex'd Spines, *commonly call'd*, Horns and Hedge-hog.
4. MEDICA *marina. Lob. Icon.* Sea *Medick* or Snail-Trefoil.

The two firſt Sorts are common in the *Engliſh* Gardens, their Seeds being frequently ſold in the Seed-ſhops in *London*; but the third Sort is pretty rare at preſent in *England*.

Theſe three Sorts may be propagated by ſowing their Seeds upon a warm dry Border the Beginning of *April*, obſerving always to do it in dry Weather; for if the Ground be very wet, or there ſhould happen much Rain ſoon after they are put into the Earth, it very often burſts and deſtroys the Seeds; but if ſome gentle Showers fall about a Week or ten Days after the Seeds are ſown, it will bring up the Plants in a ſhort Time after. When they are come up, they ſhould be carefully clear'd from Weeds, and thinn'd out to about a Foot aſunder or more (for they muſt remain where they were ſown, ſeldom ſucceeding when tranſplanted); and after this, they will require no farther Care but only to keep them clear from Weeds; and in *July* they will flower, and their Fruit will ripen in a ſhort Time after: When the Plant is in full Beauty, the firſt Sort, at a ſmall Diſtance, will appear as if it had a great Number of *Snails* upon it; and the third Sort, having large rough Heads, will make a very good Appearance: For which ſingular Oddneſs, a good Garden ſhould always have a few Plants of each Sort, eſpecially ſince they require very little Care to cultivate them.

When the Fruit is full ripe, it ſhould be gather'd and laid by in a dry Place for the Seeds; for if they are permitted to remain upon the Plants, and there ſhould Rain happen, the Seeds would ſprout in the Heads, and be deſtroy'd.

The fourth Sort is a perennial Plant, which is preſerv'd by ſuch Perſons as are very curious in collecting great Variety of odd Plants. This may be propagated by ſowing the Seeds, as the former, or by planting Cuttings during any of the Summer

Months, which if water'd and ſhaded, will take Root in a ſhort Time; after which, they muſt be planted in Pots fill'd with light ſandy Earth, and ſhelter'd in Winter under a Hot-bed Frame, where they may have a great Share of free Air in mild Weather, and only require to be ſkreen'd from hard Froſt. This Plant is preſerv'd for the beautiful Whiteneſs of its Leaves, which when intermix'd with other low Plants, makes a pretty Variety.

MEDICAGO; Moon-Trefoil.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement ariſes the Pointal, which afterwards becomes a plain orbiculated Fruit, ſhap'd ſomewhat like a Half-Moon; in which are contain'd Kidney-ſhap'd Seeds.

The *Species* are;

1. MEDICAGO *annua, trifolii facie. Tourn.* Annual Moon-Trefoil, with the Appearance of Trefoil.
2. MEDICAGO *vulnerariæ facie, Hiſpanica. Tourn.* Spaniſh Moon-Trefoil, with the Appearance of *Vulneraria.*
3. MEDICAGO *trifolia fruteſcens incana.* Shrubby Three-leav'd hoary Moon-Trefoil, by many ſuppos'd to be the true *Cytiſus* of *Virgil.*

The two firſt Sorts are annual Plants, which are preſerved in Botanick Gardens for Variety, more than any ſingular Beauty or Uſe: Theſe may be propagated by ſowing their Seeds in the Beginning of *April*, upon a Bed of light Earth, in the Places where they are to remain; for they ſeldom ſucceed when they are tranſplanted; and when they come up, they ſhould be clear'd from Weeds, and thinn'd to the Diſtance of a Foot aſunder; after which, they will require no farther Care, but only to keep them clear from Weeds, and in *July* they will flower, and their Seeds will be perfected in *Auguſt.* The Seed-veſſels of theſe Plants being ſhap'd like Half-Moons, is the only remarkable Difference between them and the *Medica's.*

The third Sort grows to be a ſtrong Shrub, and will riſe to the Height of five or ſix Feet, and may be reduc'd to a regular Head, when it will appear very beautiful: But it ſhould not be cut too often, which would prevent its Flowering; for if the Shoots are permitted to grow without much Trimming, they will produce Flowers moſt Parts of the Year, which, together with the Beauty of its Silver-colour'd Leaves, renders it worthy of a Place in every good Garden.

This Plant may be propagated by ſowing the Seeds, either upon a moderate Hot-bed, or a warm Border of light Earth, in the Beginning of *April*; and when the Plants come up, they ſhould be carefully clear'd from Weeds: But they ſhould remain undiſturb'd, if ſown in the common Ground till the *April* following; but if on a Hot-bed, they ſhould be tranſplanted about *Midſummer* into Pots, placing them in the Shade until they have taken Root: After which they may be remov'd into a Situation where they may be ſcreen'd from ſtrong Winds, in which they may abide till the Latter-end of *October*, when they muſt be put into a Frame, in order to ſhelter 'em from hard Froſts; for thoſe Plants which have been brought up tenderly, will be liable to ſuffer by hard Froſts, eſpecially while they are young. In *April* following theſe Plants may be ſhaken out of the Pots, and placed into the full Ground where they are deſign'd to remain, which ſhould be in a light Soil, and a warm Situation, in which they will endure the Cold of our ordinary Winters extremely well, and continue to produce Flowers moſt part of the Year.

Thoſe alſo which were ſown in an open Border may be tranſplanted in the *April* following in the ſame manner: But in doing of this, you muſt be careful to take 'em up with a Ball of Earth to their Roots, if poſſible; as alſo to water and ſhade 'em until they have taken Root; after which they will require little more Care than to keep 'em clear from Weeds, and to prune their Heads once a Year, *i. e.* about the Beginning of *July*, in order to reduce them to a regular Figure: But you ſhould never prune them early in the Spring, nor late in the Autumn; for if Froſt ſhould happen ſoon after they are pruned, it will deſtroy the tender Branches, and, many times, the whole Plant is loſt thereby.

Theſe Plants have been conſtantly preſerv'd in the Green-houſe, ſuppoſing 'em very tender: But I have had large Plants of this Kind, which have remain'd in the open Air in a warm Situation many Years without any Cover, and have been much ſtronger, and flower'd better, than thoſe which were houſed: Though, indeed, it will be proper to keep a Plant or two in Shelter, leſt, by a very ſevere Winter (which ſometimes happens in *England*) the Plants abroad ſhould be deſtroy'd.

They may alſo be propagated by Cuttings, which ſhould be planted in *April*, upon a Bed of light Earth, and water'd and ſhaded until they have taken Root; after which they may be expos'd to the open Air, but they ſhould remain in the ſame Bed till the *April* following before they are tranſplanted; by which Time they will have made ſtrong Roots, and may be remov'd then with Safety to the Places where they are to remain, obſerving (as was before directed) to water and ſhade them until they have taken Root: After which you may train them up with ſtrait Stems, by faſtening them to Sticks, otherwiſe they are apt to grow crooked and irregular; and when you have got their Stems to the Height you deſign them, they may then be reduc'd to globular Heads, and with pruning their irregular Shoots every Year, they may be kept in very good Order.

This Plant grows in great Plenty in the Kingdom of *Naples*, where the Goats feed upon it, with whoſe Milk the Inhabitants make great Quantities of Cheeſe: It alſo grows in the Iſlands of the *Archipelago*, where the *Turks* uſe the Wood of theſe Shrubs to make Handles to their Sabres; and the *Calogers* of *Patmos* make their Beds of this Wood.

This is, as hath been before obſerv'd, by many People ſuppos'd to be the *Cytiſus* of *Virgil*, *Columella*, and the old Writers in Huſbandry, which they mention as an extraordinary Plant, and worthy of Cultivation for Fodder; from whence ſeveral Perſons have recommended it as worth our Care in *England*. But however uſeful this Plant may be in *Crete*, *Sicily*, *Naples*, or thoſe warmer Countries, yet I am perſuaded it will never thrive in *England*, ſo as to be of any real Advantage for that Purpoſe; for in ſevere Froſt it is very ſubject to be deſtroy'd, or at leaſt ſo much damag'd as not to recover its former Verdure before the Middle or latter End of *May*; and the Shoots which are produc'd, will not bear cutting above once in a Summer, and then will not be of any conſiderable Length; and the Stems growing very woody, will render the cutting of it very troubleſome: So that upon the whole, it can never anſwer the Trouble and Expence in cultivating it, nor is it worth the Trial, ſince we have ſo many other Plants preferable to it; tho' in hot, dry, rocky Countries, where few other Plants will thrive, this may be cultivated to great Advantage, ſince in ſuch Situations this Plant will live many Years, and thrive very well.

But however unfit this may be for ſuch Uſes in *England*, yet for the Beauty of its hoary Leaves, which will abide all the Year, together with its long Continuance in Flower, it deſerves a Place in every good Garden, where being intermix'd with Shrubs of the ſame Growth, it makes a very agreeable Variety.

As there are at preſent ſo many Perſons inquiſitive to know which is the true *Cytiſus* mention'd by the Antients, I have taken the Pains of tranſcribing briefly what they have ſaid as to its Deſcription; by which may be judged how uncertain it is to determine in an Affair where there is ſo little to be found in Authors to aſſiſt us.

Theophraſtus ſays, *Cytiſus* is ſuch an Enemy to other Plants, that it will kill them, by robbing them of Nouriſhment; and that the *Medulla* of it is ſo hard and thick, that it comes the neareſt of any Thing to *Ebenum.*

The Shrub *Cytiſus*, by *Ariſtomachus* the *Athenian*, as may be ſeen in *Pliny*, [who ſays much the ſame as *Varro* and *Columella*, from whom probably he has taken it] is highly commended for Food for Sheep, and being dry, for Swine: The Utility [as to Health and Fattening; *Dal.*] the ſame as that of *Ervum*; but the Satiety is quicker, a four-footed Beaſt growing fat with a little of it, ſo that Cattle ſet light by their Barley.

No Food makes a greater Quantity, nor better Milk, and it excels all Things as to the Diſeaſes of Cattle: Moreover, being given dry, or in a Decoction of Water mix'd with Wine, to Nurſes whoſe Milk fails, it helps very much, and makes the Children ſtronger, and take to their Feet ſooner: Green, it is alſo good for them; or dry, if it be made moiſt.

Democritus and *Ariſtomachus* ſay, Bees will never want Food if they have *Cytiſus* enough, nor is any Thing cheaper.

It is ſown with Barley early in the Spring, or in Autumn.

If when the Seed be ſown, Showers be wanting, *Columella* directs, That it be water'd the fifteen following Days.

It is ſown [according to the Antients] after the *Equinoxes.* It is perfected in three Years. It is mown in the *Vernal Equinox*, [for it flouriſhes all the Winter; *Dal.*] when it has done flowering, with the cheap Labour of a Boy or old Woman.

The *Cytiſus* is hoary in Aſpect: If any one would expreſs its Likeneſs briefly, it is a Shrub of a broader Trefoil.

In Winter being moiſten'd, ten Pounds will ſatisfy a Horſe, and a leſs Quantity other Animals. Being dry, it has more Virtue, and a leſs Quantity ſatisfies.

Garlick and *Onions* grow very well between the Rows.

This Shrub was found in the Iſle *Cythnus*, thence it was tranſlated into all the *Cyclades*, and afterwards into the Cities of *Greece*, where it occaſioned a great Increaſe of Cheeſe.

It fears not the Injury of Heat nor Cold, nor Hail nor Snow; and *Hyginus* adds, nor of Enemies, becauſe the Wood is of no Value.

Alſo *Galen*, in his Book, *de Antid.* writes, " *Cytiſus* is a " Shrub. In *Myſia*, in that Part that is neareſt to our Pro- " vince, there is a Tract which they call *Brotton*, in which " there is a Place full of *Cytiſus*; from the Flowers of which, " all agree, the Bees make very much Honey.

" It is a ſruticoſe Plant. It riſes to the Height of a " *Myrtle*.

He ſays, ſeven ſimple Leaves have the Faculty of Digeſting, mix'd with warm Water, as the Leaves of *Mallows*. Thus *Galen*.

Baſil Fab. in *Theſ.* calling *Cytiſus Wiefflee* and *Spitflee*, like to the *Lotus*, and a Shrub grateful to the Goats, knows not what he writes.

Cornarus too ſecurely writes, That *Cytiſus* either never came among the *Germans*, or that it periſh'd long ago. From what *Pliny* ſays, That it was very rare in *Italy* in his Time; he cannot perſuade me, that nothing could grow in *Germany* that was ſcarce in *Italy*. *Jo. Baub.*

Strabo, contrary to *Dioſcorides*, *Pliny*, and *Galen*, will have the *Cytiſus* to be a Tree; and he likens it to the *Balſamum*, an odoriferous Tree; which probably was the Occaſion that *Cornarus* thought this Tree came neareſt to a Shrub, becauſe *Pliny* ſaid the Wood was of no Value; therefore he perſuades himſelf, that produces woody Branches, not tender and ſoft, as in an Herb.

But *Virgil* ſhews it is neither a Tree, nor a Shrub, when he ſays;

——Non me paſcente, capellæ,
Buc. Eclog. 1.
Florentem Cytiſum, & ſalices carpetis amaras.
Eclog, 9.
Sic Cytiſo paſtæ diſtendunt ubera vaccæ.
Eclog. 10.
Nec Cytiſo ſaturantur apes, nec fronde capellæ.

Virgil, I ſay, indicates very plainly in theſe Verſes, that it is neither a Tree, nor a Shrub; for Goats do not uſe it, nor can they, if they were wont to eat flowery Trees. Neither will what *Cornarus* ſays, avail, when *Pliny* ſays the Wood is of no Value, that it muſt, of Neceſſity, produce woody Branches; nay, the contrary is rather true, that there is no Value in the Wood; that it bears viney, pliable Branches, with which the Goats cannot be ſatiated.

Theocritus very plainly expreſſes it, That *Cytiſus* is a very grateful Food to Goats;

Ἡ αἲξ τον κύτισον, ὁ λύκος τὴν αἶγα διώκει.

Capra Cytiſum, lupus capellam ſequitur.

Amatus, to avoid this Difficulty, concludes *Cytiſus* to be between Trees and Shrubs, by the Difference of Genus, to be diſtinguiſh'd by *Pliny*, that, as a Tree, it may be us'd in the Feminine Gender, as a Shrub, in the Maſculine; which is not worth the minding.

Columella uſes *Cytiſus* in the Feminine Gender; and *Theocritus* and others in the Maſculine; as *Rob. Conſt.* in *Lex.* who writes, it was call'd ἀρνόφυλλον; and *Theocritus* calls this Shrub κυτιλὸν; and others, κυτισὸν; others, τηλιν.

Of *Cythnus*, or, as others, of *Cythiſa*, the Name of an Iſland, as *Severius* has it.

Among theſe Words of *Dioſcorides* in ſome Manuſcripts, there are found, falſly written, in ſome *Telinen*, *Triphyllon*, in others *Lotum Grandem*.

Dioſcorides's Deſcription of the *Cytiſus*, is not ſo accurate, that, from it, the true *Cytiſus* may be aſcertain'd; from whence it has happen'd, that different Authors have exhibited different *Cytiſus*.

The following Plants are denominated *Cytiſus*'s by the Writers in *Botany*:

Cytiſus ſiliqua incurva, folio candicante a Maranthe deſcripto.
Cytiſus Cluſ. 1. folio vireſcente.
Cytiſus montis Calcaris.
Cytiſus Hiſp. Cluſ. 2.
Cytiſus ſpicato flore.
Cytiſus 3 Hiſp. Cluſ. non brevi pediculo.
Cytiſus hirſuta.
Cytiſus Pann. Cluſ. omnia incana.
Cytiſus 2 Pannon. Cluſ. ſpecies altera hirſuta valde.
Cytiſus Pann. 3 Cluſ. ſparſis ramis.
Cytiſus Pannon. 3 Cluſ. ſpecies, altera ſupinis ramulis.
Cytiſus ſiliqua anguſta glabra.
Cytiſus glabra lata ſiliqua.
Cytiſi genus flore purpureo.
Cytiſi facie alyſſon fruticans.

Altho', in this Multitude of *Cytiſus's*, it is hard to judge which is the legitimate *Cytiſus* ſpecify'd by the Antients; the moſt Skilful take it to be that which *Maranthus* has deſcrib'd, which is our *Medicago*.

Beſides theſe, there are alſo certain other Plants that bear the Name of *Cytiſus*, which I have for good Reaſons omitted from amongſt the fore-mentioned.

Trifolium fruticans according to *Dodonæus*, or *Polemonium* according to ſome, is improperly call'd *Cytiſus* by many.

Laburnum is call'd *Cytiſus* by ſome.

Some have thought *Colutea*, as it is call'd by ſome, to be a *Cytiſus*.

Colutea Scorpioides is near a kin to *Cytiſus*, according to *Cluſius*.

Camerarius thinks *Dorycnium Monſpelienſium*, as it is accounted, to be akin to the *Cytiſus* of *Columella*.

Trifolium Candidum Dodon. by ſome, is ſaid to be the *Cytiſus* of *Columella*; concerning which, ſee *Lib. Hiſt. n.* 9. 17. of *Trifolious Herbs*.

Some will have the *Cytiſus* of *Marcellus Empiricus*, and alſo of *Dioſcorides*, *Columella*, and *Virgil*, to be a certain great *Trefoil*.

Tragus writes, That their Opinion is to be rejected, who interpret the *Trifolium Pratenſe* to be a *Cytiſus*.

Some contend, That the *Trifolium Candidum* of *Dodon.* the *Rectum Melilotum Vulgarem* to be the *Cytiſus* of the Antients, as *Dodonæus* ſays; but they have not hit on the Truth.

Ruellus writes, That he was afraid, that *Marcellus* took *Cytiſus* for *Medica*.

The *Lotus Sativa Odorata* is by ſome thought to be the *Cytiſus*, but others do not approve of it.

MEDLAR. *Vide* Meſpilus.

MELAMPYRUM; [Μελάμπυρον, of μέλας, *Black*, and πυρὸς, *Wheat*] Cow-Wheat.

The *Characters* are;

The Leaves grow oppoſite by Pairs; the Flower conſiſts of one Leaf, is of an anomalous perſonated Figure, and divided into two Lips; the uppermoſt of which has a Spur, but the under one is intire; the Fruit is round, and divided into two Cells, containing Seeds reſembling Grains of Wheat.

The *Species* are;

1. MELAMPYRUM *luteum latifolium. C. B. P.* Yellow broad-leav'd Cow-Wheat.
2. MELAMPYRUM *luteum anguſtifolium. C.B.P.* Narrow-leav'd Yellow Cow-Wheat.
3. MELAMPYRUM *coma purpuraſcente. C. B. P.* Cow-Wheat, with purpliſh Tops.

The two firſt Sorts are very common in Woods and ſhady Places, growing near the Foot of Trees in divers Parts of *England*, and are never cultivated in Gardens.

The third Sort is very rarely found wild in *England*; but, in *Weſt-Frieſland* and *Flanders* it grows very plentifully among the Corn; and *Cluſius* ſays, it ſpoils their Bread; making it dark, and that thoſe who eat of it, us'd to be troubled with Heavineſs of the Head, in the ſame Manner as if they had eaten *Darnel* or *Cockle*; but Mr. *Ray* ſays, He has eat of this Bread very often, but could never perceive that it gave any diſagreeable Taſte, or that it was accounted unwholeſome by the Country People, who never endeavour to ſeparate it from the Corn; and *Tabernemontanus* declares, He has often eaten it without any Harm, and ſays, it makes a very pleaſant Bread. It is a delicious Food for Cattle, particularly for fattening of *Oxen* and *Cows*: For which Purpoſe it may be cultivated in the ſame Manner as hath been directed for the *Fagopyrum* or *Buck-Wheat*: It loves a light ſandy Soil.

MELIANTHUS; [Μελίανθος, of μέλι, *Honey*, and ἄνθος, *Flower*] Honey-Flower.

The *Characters* are ;

It hath a perennial Root ; and the Appearance of a Shrub ; the Leaves are like thoſe of Burnet ; *the Cup of the Flower is divided into ſeveral Parts ; the Flower conſiſts of four Leaves, and is of an anomalous Figure ; the Petals (or Leaves) are placed ſometimes in the Shape of a Fan, and at other Times are of a conical Figure ; the Ovary becomes a Fruit reſembling a Bladder four-corner'd, divided into four Cells, and pregnant with roundiſh Seeds.*

The *Species* are ;

1. MELIANTHUS *Africanus. H. L.* The large Honey-flower, *vulgarly called*, The Locus *or* Wild Honey.
2. MELIANTHUS *Africanus minor fœtidus. Com. Rar.* The ſmaller ſtinking Honey-flower.

The firſt of theſe Plants is pretty common in many *Engliſh* Gardens, where it is preſerv'd as a Curioſity. This produces large Spikes of Chocolate-colour'd Flowers in *May* ; in each of which is contain'd a large Quantity of a black ſweet Liquor, from whence it is ſuppos'd to derive its Name.

This Plant was formerly preſerv'd in Green-houſes as a tender Exotick ; but, if planted in a dry Soil, and a warm Situation, will endure the Cold of our ordinary Winters very well ; and if, in a ſevere Froſt, the Tops of them ſhould be deſtroyed, yet the Roots will abide, and put forth again the ſucceeding Spring, ſo that there is no great Danger of loſing it ; and the Plants which grow in the open Air, do always flower much better than thoſe which are preſerv'd in the Green-houſe, as being leſs drawn, which always is hurtful to the flowering of Plants, and many Times prevents their producing any Flowers.

This Plant may be propagated by taking off its Suckers or Side-ſhoots any Time from *March* to *September*, obſerving to chuſe ſuch as are furniſh'd with Fibres ; and after they are planted, you muſt water, and ſhade them, until they have taken Root, after which they will require no farther Care but to keep them clear from Weeds. They may alſo be propagated by planting Cuttings, during any of the Summer Months ; which, if watered and ſhaded, will take Root very well, and may afterwards be tranſplanted where they are deſign'd to remain.

The ſecond Sort is leſs common than the former, and only to be found in ſome curious Collections of Plants, tho' it ſeems to be equally as hardy as the former. This produces leſſer Spikes of Flowers, but they are much more beautiful than the former, their Flowers having a Mixture of Red, Green, and Yellow. This produces its Flowers in *May*, and ſometimes perfects its Seeds with us, by which it may be propagated : And the Plants obtain'd from ſuch Seeds, would be hardier than thoſe which come from abroad, or are rais'd from Slips. This may be propagated in the ſame Manner as the former, and requires much the ſame Culture, tho' it is commonly preſerv'd in the Green-houſe ; but I have ſeen Plants of this Kind which were growing in the Gardens of *Charles du Bois*, Eſq; at *Mitcham* in *Surrey*, under a warm Wall, which produced a greater Quantity of Flowers, and ripen'd their Seeds better than any of thoſe Plants which are preſerv'd in the Green-houſe. This Sort commonly grows to a greater Height than the former, and its Branches become more woody.

MELILOTUS ; [μελίλοτος, of μέλι, *Honey*, and *Lotus*, the *Lote-tree*, which was a celebrated Plant among the Antients : It was call'd the *Honey Lotus*, becauſe Bees do not collect more and ſweeter Honey from any Herb than from this Plant ; but it is not ſo call'd on account of its Taſte, for the Leaves, Flowers, and Fruit of it are bitter] Melilot.

The *Characters* are ;

It hath a papilionaceous Flower ; out of whoſe Empalement ariſes the Pointal, which afterwards becomes a naked Capſule, that is not hid in the Empalement, (as in Trefoil) pregnant with one or two roundiſh Seeds : To theſe Notes may be added, the Leaves grow by Threes on the Footſtalks, and the Flowers are produc'd in a Spike.

The *Species* are ;

1. MELILOTUS *officinarum Germaniæ. C. B. P.* Common Melilot.
2. MELILOTUS *fruticoſa candida major. Mor. Hiſt.* Shrubby Melilot, with a white Flower.
3. MELILOTUS *major odorata violacea. Mor. Hiſt.* Greater ſweet-ſcented Melilot, with a Violet-colour'd Flower, *commonly called*, Sweet Trefoil, *or* Lotus Urbana.
4. MELILOTUS *corniculis reflexis, major. C. B. P.* Greater Melilot with reflected Horns.
5. MELILOTUS *corniculis reflexis, minor vel repens. C.B.P.* Smaller creeping Melilot, with reflexed Horns.
6. MELILOTUS *Italica, folliculis rotundis. G. B. P. Italian* Melilot, with round Leaves.
7. MELILOTUS *anguſtifolia repens, folliculis rotundis. C. B. P.* Narrow-leav'd creeping Melilot, with round ſmaller Leaves.
8. MELILOTUS *lutea minor, floribus & ſiliculis minoribus, ſpicatim & densè diſpoſitis. Mor. Hiſt.* Smaller yellow Melilot, with ſmaller Flowers and Pods, growing in a thick Spike.
9. MELILOTUS *Meſſanenſis procumbens, folliculis rugoſis ſublongis, ſpicis florum brevibus. Raii Syn.* Trailing Melilot of *Meſſina*, with rough oblong Leaves, and ſhort Spikes of Flowers.
10. MELILOTUS *Cretica humillima humifuſa, flore albo magno. Tourn. Cor.* Low Melilot of *Crete*, with a large white Flower.
11. MELILOTUS *capſulis reni ſimilibus, in capitulum congeſtis. Tourn.* Melilot Trefoil *or* Noneſuch.

The firſt Sort here mention'd, is that uſed to make the *Melilot Plaiſter :* This is found wild in ſeveral Parts of *England*, but is generally cultivated in ſome Gardens near *London*, from whence the Markets are ſupply'd with it. The ſecond Sort is by ſome ſuppos'd to be only a Variety of the firſt, differing in the Colour of its Flowers, but this is a Miſtake, for the whole Plant has a very different Appearance, the Leaves being narrower, the Stalks much taller, nor has it near ſo ſtrong a Scent. The third Sort is ſometimes uſed in Medicine, but is rarely cultivated except in Botanick Gardens.

Theſe may be all cultivated by ſowing their Seeds in *March*, upon a Bed of light Earth ; and when the Plants are come up, they ſhould either be tranſplanted out, or hough'd, ſo as to leave 'em eight or ten Inches aſunder, (eſpecially the two firſt Sorts, which will abide two or three Years, and grow very large) obſerving to keep them clear from Weeds, and the *Auguſt* following they will flower ; when they may be cut for Uſe, which will cauſe them to puſh out new Shoots, whereby the Roots will be maintain'd thro' the Winter, and flower in *May* or the Beginning of *June* the ſucceeding Year. The cutting off the Shoots when the Plant is in flower, will maintain the Roots much longer than if they were permitted to ſtand till the Seeds are ripe, ſo that thoſe Roots you intend for Seeds, muſt not be depended on to ſtand very long.

The third Sort is an annual Plant, which may be ſown as the two former, but ſhould not be tranſplanted, but rather houghed out to the Diſtance of five or ſix Inches, and permitted to remain in the ſame Place, obſerving to keep them clear from Weeds, and they will flower in *June*, and their Seeds will be ripe in *Auguſt*.

The fourth, fifth, ſixth, ſeventh, eighth, and ninth Sorts are annual Plants, which grow wild in the South of *France*, and in *Italy*, from whence the Seeds of them have been procured by ſuch Perſons who are curious in Botany. Theſe Sorts are all of them preſerved in Botanick Gardens for Variety, but they are Plants of no great Beauty, nor are they uſed in Medicine. But if there were Trials made of ſome of the Kinds, I believe they might be found uſeful to ſow for feeding of Cattle, as the laſt Sort here mentioned is at preſent in divers Parts of *England*, which was the Reaſon of my enumerating theſe Sorts here. For as ſome of the other Sorts are very hardy, and will grow on almoſt any Soil, ſo if they are found to be equally good with the Noneſuch, they may be better worth cultivating, becauſe they are of much larger Growth ; ſo conſequently will produce much more Fodder on an Acre of Land, than that will. But as I have had no Opportunity of trying if Cattle will eat any of them, ſo I cannot recommend them, but by way of Trial, to ſuch Perſons who are curious in making theſe Sorts of Improvement.

As theſe are annual Plants, ſo their Seeds muſt be ſown every Year ; or if they are permitted to ſcatter when ripe, the Plants will come up in Autumn, and will abide the Winters Cold very well in this Country ; thoſe Plants which come up in the Autumn, will grow much larger than thoſe which are ſown in the Spring, and will more certainly produce good Seeds. Therefore thoſe Perſons who are curious to preſerve their Kinds, ſhould either ſow them in Autumn ſoon after the Seeds are ripe, or permit them to ſcatter their Seeds ; and the ſelf-ſown Plants may be eaſily tranſplanted, where they are deſigned to grow ; and they will require no farther Care, but to keep them clear from Weeds. They will all of them grow on almoſt any Soil ; but they will thrive better on dry light ſandy Soil, than on a ſtiff clayey Ground.

The tenth Sort is an abiding Plant, which rarely produces Seeds in this Country, ſo is propagated by parting of the Roots in the Spring. This Sort is not ſo hardy as the others; therefore ſome of the Plants ſhould be preſerved in Pots, that they may be removed into Shelter in Winter; for very hard Froſts will deſtroy them, if they are expoſed. But they muſt always have as much free Air as poſſible in mild Weather, ſo that if they are placed under a common Hot-bed Frame in Winter, where the Glaſſes may be drawn off every Day in mild Weather, and only covered in hard Froſt, the Plants will thrive much better than where they are placed in a Green-houſe. In Summer the Plants muſt be frequently watered in dry Weather, and kept clear from Weeds, which is all the Culture they require.

The *Noneſuch* which is now cultivated in the open Fields in ſeveral Parts of *England*, is an Inhabitant of this Kingdom; growing wild by the Sides of Paths, and on arable Land, in great Plenty every where near *London*; and if the Seeds are permitted to ſcatter, there will be a Supply of Plants to ſtock the Ground, ſo that it often becomes a very troubleſome Weed in Gardens, and is difficult to extirpate after it hath gotten Poſſeſſion.

The Seeds of this Plant are ſown in the Spring, either alone, or with *Barley*, the latter of which I ſhould recommend; for as this is a low trailing Plant, ſo it will not injure the *Barley*, which will get forward before the *Noneſuch* comes up; and if there doth not ariſe a great Crop of the *Noneſuch*, yet being permitted to ſtand until the *Barley* is ripe, the Seeds of the *Noneſuch* will be ripe, and moſt of it ſcattered, by that Time; and after the Corn is taken off, the Rains in Autumn will ſoon bring up the Plants, which will flouriſh all the Winter, and the Spring following will afford an early Feed for Cattle.

Where this Plant is ſown by itſelf, it muſt not be fed or mow'd, until the Seeds are ripe; for as it is an annual Plant, ſo where it is eaten, or cut down, the Roots will periſh; and if there is not a Supply of young Plants to ſucceed them, the Crop will be deſtroyed in one Seaſon. Indeed, as theſe Plants begin to flower very young, and near their Roots, ſo before the Seeds are formed at the Extremity of the Shoots, thoſe produced near the Root will be ripe and ſcattered, from whence young Plants will come up, and ſupply the Crop; which has deceived ſome Perſons, who have thought this Plant will abide two or three Years, and produce ſeveral Crops from the ſame Roots; which is a great Miſtake, for the Root periſhes annually. But as the Plants produce ſuch Quantities of Seed, at almoſt every Joint of the Stalks, ſo it is almoſt impoſſible to deſtroy the Crop totally, if the Plants are permitted to grow to any Size, before they are fed or cut down.

The Seeds of *Noneſuch* being ſmaller than Clover-ſeed, a leſs Quantity will ſow an Acre. If it is ſown by itſelf, there ſhould be ten Pounds allowed to an Acre; but if it is ſown with *Barley*, ſix Pounds will be ſufficient. When it is ſown with *Barley*, the *Barley* ſhould be firſt ſown and harrowed, and then the Seeds of the *Noneſuch* ſhould be ſowed, and the Land rolled, which will bury this Seed deep enough.

MELISSA; [ſo call'd of μέλι, *Honey*, becauſe in making *Honey* you procure it from this Plant: It is alſo call'd *Meliſophyllon*, of μέλι, and φύλλον, a *Leaf*, q. d. *Honey-leaf*: It is alſo call'd *Apiaſtrum*, of *Apis*, Lat. a *Bee*, becauſe *Bees* are delighted with this Plant] Balm.

The *Characters* are;

It is a verticillate Plant, with a labiated Flower, conſiſting of one Leaf, whoſe Upper-lip is roundiſh, upright, and divided into two; but the Under-lip is cut into three Parts: Out of the Flower-cup riſes the Pointal, which is attended, as it were, with four Embryo's; theſe afterwards turn to ſo many Seeds, which are roundiſh, and incloſ'd in the Flower-cup. To theſe Notes may be added, the Flowers are produc'd from the Wings of the Leaves, but are not whorled quite round the Stalks.

The *Species* are;

1. MELISSA *hortenſis. C. B. P.* Garden Balm.
2. MELISSA *hortenſis, foliis ex luteo variegatis.* Garden Balm, with yellow variegated Leaves.
3. MELISSA *Romana, molliter hirſuta & graveolens. H. R. Par.* Stinking Roman Balm, with ſofter hairy Leaves.

There are ſome other Species of this Plant which are preſerv'd in curious Gardens for Variety; but as they are never cultivated for Uſe, ſo I ſhall paſs them by without naming.

The firſt of theſe Sorts is cultivated in Gardens for Medicinal and Culinary Uſe: This is propagated by parting the Roots, either in Spring or Autumn, planting the Slips at about eight or ten Inches Diſtance, in Beds about four Feet wide, leaving a Path two Feet between the Beds, for the Conveniency of cleaning, watering, and cutting the Plants.

When they are firſt planted, if the Seaſon proves dry, you muſt carefully water them until they have taken Root, otherwiſe they will be ſubject to decay, but afterwards they will require no farther Care, but only to keep them clear from Weeds. Theſe Plants ſhould be tranſplanted and parted every other Year, otherwiſe their Roots will grow ſo large as to injure each other, and for want of Room will rot and decay.

The variegated Sort makes a very pretty Appearance in the Spring Seaſon, while the Leaves are young, but afterwards their Beauty goes off; however, a few Plants of this Sort may be planted in large Borders for Variety.

The third Sort is a Plant of no great Beauty or Uſe, but is preſerv'd in ſeveral curious Gardens for Variety. This is ſomewhat tender, and ſhould have a dry Soil, and a warm Situation, otherwiſe it is ſometimes deſtroy'd in ſevere Froſts.

The two firſt Sorts will grow in almoſt any Soil or Situation; but the ſtrip'd Sort ſhould not have a rank Soil, which would cauſe it to grow vigorouſly, whereby the Beauty of its variegated Leaves ſoon goes off.

MELISSA TURCICA. *Vide* Moldavica.

MELO, [takes its Name of μῆλον an *Apple*, becauſe the Fruit reſembles an *Apple*: The *Italians* call it *Milo*, as tho' of *Mille*, Lat. a *Thouſand*, becauſe ſcarce one of a thouſand is found to be good] A Melon.

The *Characters* are;

The Flower conſiſts of one Leaf, which is of the expanded Bell-ſhape, cut into ſeveral Segments, and exactly like thoſe of the Cucumber; ſome of theſe Flowers are barren, not adhering to the Embryo; others are fruitful, growing upon the Embryo, which is afterwards chang'd into a Fruit, for the moſt part of an Oval-ſhape, ſmooth or wrinkled, and divided into three ſeminal Apartments, which ſeem to be cut into two Parts, and contain many oblong Seeds.

The *Species* are;

1. MELO *vulgaris. C. B. P.* Common Musk Melon.
2. MELO *rotundus parvus. C. B. P.* Small round Musk Melon, *commonly call'd*, The Portugal or Pocket Melon.
3. MELO *reticulatus. J. B.* Netted or wrought Melon.
4. MELO *magnus, cortice virente, ſemine parvo. J. B.* Greater Musk Melon, with a ſmooth green Skin, and a ſmall Seed.
5. MELO *Hiſpanicus, cortice alba intus rubente.* White Spaniſh Melon, *vulgo.*
6. MELO *cortice lævi intus virente.* The Green-fleſh'd Melon, *vulgo.*

As there is not any Plant cultivated in the Kitchen-Garden, which the Gardeners near *London* have a greater Ambition to produce early and in Plenty; ſo there is a great Number of Methods now practis'd in the raiſing and dreſſing of the Vines, in order to obtain them in greater Perfection: But to enumerate them all in this Place, would greatly exceed my intended Bounds; therefore I ſhall only ſet down the plain and eaſy Method, whereby a Perſon may depend on having a good Crop of *Melons*, whenever the Seaſon is tolerably good for them, provided the Seed be good, and the Directions duly follow'd.

And firſt, as to the Choice of Seed: In this you muſt be careful, becauſe the whole Succeſs of your Labour and Expence depends upon it. You ſhould annually (if poſſible) exchange your Seeds, and not continue to ſave and ſow the ſame for ſeveral Years in the ſame Ground; for they will certainly degenerate in two or three Years, and from being extraordinary good Sorts, will become very bad; therefore you ſhould purchaſe ſome good *Melons* from ſome Gardens at a great Diſtance from you; which Seed (provided the Fruit was well-taſted, high-colour'd, and of a firm Nature) ſhould be carefully preſerv'd two or three Years before it be ſown; when will not be ſo ſubject to produce ſtrong luxuriant Vines, bu will be more productive of Fruit (for as I have obſerv'd, tha by keeping theſe Seeds, they annually loſe of their Weight ſo it is certain, that the watry Parts do firſt evaporate; an theſe are what promote Luxuriancy in all Plants, therefore th more of theſe are loſt by keeping, *&c.* the more fruitful wi the Plants be): but it muſt be obſerv'd, that although the

See

Seeds will retain their growing Quality for eight or ten Years, yet they are not near ſo good at that Age (whatever may have been ſaid to the contrary); for the Plants produc'd from ſuch Seeds are generally too weak to produce Fruit of any conſiderable Size, and Seed of three or four Years old is by the beſt Judges always preferr'd.

But if you cannot obtain Seeds of that Age, and are oblig'd to ſow new ones, then you ſhould either carry it in your Breeches Pocket, where it may be kept warm, or plac'd at a proper Diſtance from a Fire two Months before it be ſown; by which means the watry Parts will be carry'd off, and the Seed prove equally as good as if it had been kept two or three Years, as hath been experienc'd by ſeveral curious Perſons.

There are commonly great Quantities of *Melon* Seed brought into *England* annually as great Curioſities, which often tempts the Gardeners to ſow it, expecting ſomething very extraordinary from it; but it ſeldom happens that it ever proves good; therefore great Care ſhould be taken to know from whence it comes; by which may be gather'd how proper it is for our Climate, and alſo ſome Judgment made of the Goodneſs of the Sorts: For thoſe *Melons* which are produc'd in the *Weſt-Indies*, are generally very large, and being brought from a very hot Country, ſeldom come to any thing in *England*; and thoſe Seeds which come from *Spain*, *Italy*, or the *Levant*, are ſeldom good for much, the Gardeners in thoſe Countries being very careleſs in ſaving their Seeds: But the beſt Country to procure *Melon* Seeds from, is *Languedoc* in the South of *France*, where the Gardeners emulate each other in producing the fineſt *Melons*, and the Seeds brought from thence are much preferable to any ſav'd in *England*, and do ſucceed better than thoſe brought from moſt other Countries.

Having thus largely treated of the Choice of Seeds, I ſhall now proceed to the Method and Times of ſowing them; which, according to the common Practice of the Gardeners near *London*, is at two Seaſons; *viz.* The firſt (which is for the early Crop, to be planted under Frames) in the latter end of *January*, or the Beginning of *February*; tho' indeed there are ſome who, endeavouring to produce early Fruit, ſow their Seeds in *December*, but then there muſt be a great Expence and Care, otherwiſe they will come to nothing. So that the moſt certain Seaſon is that before-mention'd: for if by great Care the Plants which are rais'd ſooner are preſerv'd in Health, yet when the Fruit firſt appears, if the Beds are not in good Temper for Heat, and great Care be not taken in giving them a juſt Proportion of Air, the Fruit will fall off, and come to nothing. The ſecond Seaſon for ſowing this Seed (which is for Bell or Hand-Glaſſes) is about the Beginning of *March*, or a little later, according to the Earlineſs or Lateneſs of the Seaſon; and is the general Crop of *Melons*, which are commonly ripe in *July* or *Auguſt*: But I ſhall firſt begin with Directions for Raiſing and Managing the early Crop for Frames.

About ſeven or eight Days before you intend to ſow the Seeds, you muſt prepare a Parcel of new Horſe-Dung from the Stable, which ſhould be caſt up (together with the Litter) into a round Heap, mixing therewith a few Sea Coal Aſhes, which will help to preſerve the Heat of the Dung. After it has lain in the Heap a Week, it will have acquir'd Heat enough for the Purpoſe: You muſt therefore dig a Trench the Length and Width of the Frame you intend for the Bed, and about a Foot deep (provided the Ground be dry; but if it be wet, the Trench ſhould not be above three or four Inches deep); into this Trench you muſt lay the Dung, obſerving to ſhake and work it well with the Fork, ſo that every Part of it may be equally ſtirr'd, whereby it will ſettle all alike; and it ſhould be beaten down with the Fork, to prevent the Heat from going off too ſoon: This Dung ſhould be laid three Feet thick; and after having made it exactly level on the Top, you ſhould lay ſome fine light Earth thereon, about three Inches thick, on which the Seeds ſhould be ſown two Days after the Bed is made, covering it about half an Inch with the ſame light Earth. If after the Seed be ſown, the Bed ſhould prove very hot, you muſt raiſe the Light with a Stone about an Inch high, which will make Way for the Steam of the Bed to paſs off: but if it ſhould prove cool, you muſt lay ſome Litter about the Sides, and cover the Glaſs well with Mats or Straw every Night, and in bad Weather, which will ſoon bring it to a Heat. In about five Days after the Seed is ſown, the Plants will appear above Ground; when you muſt carefully give them Air, to prevent their being ſuffocated by the Steam of the Bed, as alſo turn the Light every Day, when the Weather is fair, to dry off the Damp which ſettles upon the Glaſs; and if the Weather ſhould not admit of the Light lying the wrong Side upwards to dry, then you muſt only turn it, and wipe off all the Moiſture with a Woollen Cloth, and turn the Light again; for if the Moiſture which is collected upon the Underſide of the Glaſs be ſuffer'd to fall upon the Plants, it will occaſion their changing yellow, and cauſe them to be very weak; for this proceeds from the Steam of the Dung and Earth, and the Perſpiration of the Plants, which being confined and mix'd together, becomes of a rancid Nature, and ſo proves deſtructive to whatever Plants it lodges upon, or that imbibe any Part of it.

You ſhould alſo, ſo ſoon as the Plants appear, caſt up a freſh Heap of new Dung, as before; and after having lain in the Heap about ſix Days, you muſt make a new Bed in the Manner before directed, covering the Dung three Inches thick with good freſh light Earth; then put on the Frame and Glaſſes, and let it remain two or three Days, for the great Heat to paſs off before you ſet the Plants therein, that the Bed may be of a moderate Temper, otherwiſe the Roots of the Plants will burn. When you find your Bed of a proper Temper for Heat, which you may eaſily know, by thruſting your Finger down in the Earth, letting it remain a ſmall time, and if you feel no violent Heat, then you may be ſure there will be no Danger of injuring them thereby: therefore you ſhould take up the Plants carefully out of the Seed-bed, (raiſing them with your Finger, that the Roots may not be injured) and prick them into the new Bed, about three Inches Diſtance each Way, covering the Glaſſes with Mats, if the Sun ſhould be warm, till they have taken Root; after which you muſt be very careful to give them Air in Proportion to the Heat of the Bed, otherwiſe they will draw up very weak, and change yellow. You muſt alſo, as the Stems of the Plants advance in Height, put in ſome dry freſh Earth between them, to Earth the Shanks, which will greatly increaſe their Strength; and be very careful to wipe the Moiſture off from the Glaſſes, as was before directed, for the Reaſons already laid down; and proportion your Covering of Mats every Night to the Heat of the Bed.

In about a Fortnight after the Plants are prick'd out, they will begin to ſhew the third (or what, in the Gardeners Language, is call'd the rough) Leaf; at which time you muſt be provided with a freſh Parcel of new Dung in Proportion to the Quantity of Lights you intend to plant, allowing a full Load (which commonly contains fourteen good Wheel-barrows) to each Light: when the Dung has lain in the Heaps ſix or eight Days, you muſt dig out a Trench in Proportion to the Length and Breadth of your Frames, and about a Foot deep, if the Soil be dry, but if wet, four or five Inches will be ſufficient: then wheel the Dung therein, obſerving to ſhake and work it equally in every Part of the Bed, that the Heat may be equal; and after having laid it even and level, you ſhould lay on the Earth (obſerving to break it very fine) about three Inches thick, laying it exactly even; then put on the Frames, and in the Middle of each Light, where the Plants are to be planted, you ſhould put a good Baſket full of freſh light rich Earth, raiſing it into a little Hill; then cover the Beds with the Lights, letting it remain two or three Days, till you perceive it is of a proper Temper for Heat; when you muſt take the Plants carefully out of the former Bed, and after having levell'd the Hills in the Middle of each Light on the Top, and made it a little hollow, to contain a ſmall Quantity of Water, you ſhould ſet two ſtrong Plants into each, obſerving to give them a little Water if the Earth be dry, as alſo to ſhade them from the Sun until they have taken Root; after which you muſt be careful to give them Air, according to the Proportion of the Heat of the Bed, as alſo to turn the Glaſſes to dry them. And when the Plants have put out the fourth Leaf, (which is what the Gardeners term having two Joints) you ſhould pinch off the extreme Part of the Shoot, in order to force out lateral Branches or Runners; which when they have produced about ſix Inches long, ſhould be regularly placed in the Manner they are deſigned to remain; for theſe Shoots ought never to be diſplaced, or the Leaves bruiſed with the Hand, which is very injurious to them; therefore you ſhould conſtantly keep them clear from Weeds, and as the Shoots are produced, lay them in their true Order, ſo as not to croſs or intangle with each other; but by no means ſhould you ſtop them, as is too often practiſed, which occaſions their putting forth a greater number of Shoots; but then they are the weaker, and ſo there is a Confuſion of Vine, but thoſe not ſtrong enough to produce any conſiderable Fruit, nor will the firſt *Melons*, which appear upon ſuch Vines, remain, but, on the contrary, fall away, and come to nothing.

Theſe Plants ſhould be often refreſh'd with Water, but you muſt be careful not to give them too much; and when the Vines have grown off from the little Hill upon which they were planted, you ſhould water them gently all over their Leaves, which will greatly refreſh them; but you ſhould be careful not to do this in the Heat of the Day, leſt the Sun, by immediately exhauſting the Moiſture, ſhould ſcorch the Leaves of the Plants; nor ſhould it be done late in the Evening; for the Glaſſes being then put down cloſe, and cover'd with Mats or Straw, the Moiſture which always ariſes after ſuch Waterings, where there is a Warmth in the Beds, being pent in, will become rancid, and mixing with the Air, will occaſion its being hurtful to the Plants; therefore the beſt Time is about Seven or Eight of the Clock in the Morning, according to the Seaſon of the Year; and when you find the Sun ſhines hot upon the Glaſſes, you ſhould raiſe them, to let the Steam paſs off, and in the Middle of the Day, in very hot Weather, the Glaſſes ſhould be ſhaded with Mats or Straw, which will prevent their ſcorching, and preſerve a gentle Moiſture in the Bed, which is abſolutely neceſſary for the Growth of Plants.

When your Fruit begins to appear, you will at the ſame time perceive a great Number of Male Flowers, (which the Gardeners call falſe Bloſſoms, and are eaſily diſtinguiſh'd from the fruitful ones, by their being produced upon a ſlender Pedicle; whereas the fruitful ones are always faſten'd to the Top of the young Fruit) theſe are by many Perſons carefully pick'd off, as ſuppoſing that they weaken the Plants, and are injurious to the young Fruit; but this is a very great Miſtake, (as I have more than once experienced) for they are abſolutely neceſſary to impregnate the Ovary of the fruitful Flower: which when done, the Fruit will ſoon ſwell and grow large; but if this be obſtructed, they ſeldom come to any thing, but on the contrary, change yellow, and fall off: therefore I would caution every one againſt the nice pruning of *Melons*, in which they are ſo liable to commit Miſtakes; whereas on the contrary, when they never do any thing more but only ſtop the firſt leading Shoots, to encourage their producing ſtrong Runners, there is no Danger of miſcarrying, if the Vines are but kept clear from Weeds, and not tumbled or bruiſed, but carefully attended with Water, *&c.* then the natural Growth of the Plants not being obſtructed, you need not fear Succeſs.

During the Growth of the *Melons* you ſhould conſtantly attend them with Water, being cautious not to give them too much; but when the Fruit is arriv'd to a conſiderable Bigneſs, you ſhould intirely forbear watering them, or at leaſt do it very ſparingly; for the Water which is then given them, does but contribute to the making them large and ill-taſted, which ſhould always be avoided; for a middle-ſized well-taſted Fruit is far preferable to the moſt monſtrous, watery, green, ill-taſted *Melon* that was ever produced.

When the Fruit begins to ripen, (which you may know by the changing its Colour, and emitting an Odour when cloſely ſmell'd to) you ſhould turn it every Day, that every Side of the *Melon* may be expoſed to the Sun, that it may be equally ripen'd on all Sides: and if you intend to eat it ſoon after it is gather'd, you ſhould let it remain upon the Vines until it changes pretty yellow, and the Stalks ſeem to ſeparate from the Fruit; then you ſhould cut it off in the Morning before the Sun is too hot, obſerving to preſerve two Inches of the Stalk to the Fruit, otherwiſe it will loſe of its Richneſs: But when the Fruit is to be ſent to any Diſtance, ſo that it will be two or three Days before it is eaten, then you muſt obſerve not to let it be too ripe before it be cut; for it will be little worth, after being kept two or three Days.

If the above-mention'd Directions be duly obſerved, you will not have Occaſion to pull off the Leaves from the Vines, to admit the Sun to the Fruit, as is often practiſed, tho' very abſurdly; for the Fruit will always thrive much better where it has a gentle Coverture of Leaves, than when it is too much expoſed to the Sun, which hardens the outer Skin, and prevents its kindly Growth, whereby it is render'd tough and ill-taſted.

But notwithſtanding I have adviſed the planting out the *Melon* Plants upon the Hills in the Middle of each Light, yet if any Perſon is very curious to have early Fruit, the beſt Method is to plant them in Baſkets, (in the Manner as was directed for *Cucumbers*, under which Head you will find proper Inſtructions how they are to be managed, until they are ridged out into the Frames for good, which ſhould not be done till the Flowers begin to appear;) after which the Management muſt be the ſame as hath been before inſerted, both as to Pruning, Watering, *&c.* therefore I ſhall forbear repeating either of thoſe Articles in this Place, but ſhall now proceed to the Method practiſed by the moſt ſkilful Gardeners, for the ſecond or general Crop of *Melons*, which are raiſed commonly under Bell or Hand-glaſſes.

The Seaſon for ſowing the Seed for this Crop, is (as I before mention'd) about the Beginning of *March*, and may be put into the Upper-ſide of the Hot-beds, where your early *Melons* or *Cucumbers* are planted; in which Place they will ſoon come up, and may then be taken up and tranſplanted into a new Hot-bed, and cover'd either with Hand-glaſſes or Frames, (according as you have Conveniency) obſerving to refreſh them with Water, as alſo to ſhade them, until they have taken Root; after which you muſt let them have a great Share of freſh Air when the Weather is good, that the Plants may grow ſhort and ſtrong; and obſerve to earth up their Stems, as they advance, with light Earth, which will greatly encourage the Plants.

About the Beginning of *April* the Plants will put out their rough Leaves; at which Time you ſhould be provided with a Quantity of new Dung, in proportion to the Number of Holes intended, (always allowing a good Load of Dung to five Holes, which is the common *Quantum*) which ſhould be caſt into a Heap for ſix or ſeven Days, mixing therewith a few Sea-coal Aſhes; and when the Dung is in a proper Temper for uſing, you muſt dig a Trench, the Length whereof ſhould be according to the Number of Glaſſes you intend in each Row, allowing them three Feet Diſtance, and in Width two Feet and an half: But the Depth muſt be proportion'd to the Moiſture or Dryneſs of the Soil; in a dry one it ſhould be ten Inches deep, but in a moiſt Soil two or three Inches will be enough; then you muſt wheel the Dung therein, obſerving to ſhake and work every Part of it equally, and to lay it of an equal Thickneſs, as alſo to make the Sides ſtrait: Then having laid the Dung even, you muſt mark out the Places intended for the Holes, at each of which you muſt lay a Baſket full of freſh light rich Earth, thruſting in a Stick about two Feet long into the Middle, which muſt remain for a Mark where the Hole is to be made; then cover the Dung all over, both Top and Sides, with the Earth that came out of the Trench, laying it exactly ſmooth and even, about three Inches thick, or ſomewhat more: Then put the Glaſſes on over each Stick, letting them remain cloſe down two Days, by which time the Dung will have warm'd the Earth ſufficiently to receive the Plants: You ſhould therefore draw out the Sticks, and with your Hand level the Top of the Hill, breaking the Clods, and laying it hollow like a Diſh, to retain the Water given to them; then take the Plants up carefully from the other Bed, and put two ſtrong ones into each Hole, obſerving to water and ſhade them until they have taken Root.

Thus having made one Ridge, you may continue to make as many more as you have Glaſſes for, allowing ſix Feet between each Ridge, for a Path to go between them; which, at the firſt making the Ridges, may ſeem a great deal; yet after the Vines have run, and the Sides of the Ridges made up, to ſupport them, there will not be above two Feet left for a Path, which is as little as can well be allow'd.

Your Plants having made new Roots, and put out a fourth Leaf, you ſhould nip off the Top of each, to force out Runners from the Bottom, (as was before directed for thoſe in Frames) and as the Weather increaſes warm, ſo you ſhould always raiſe up the Glaſſes on the South Side with Stones, in the Middle of the Day, to give them Air, which will cauſe them to be very ſtrong; and alſo give them a little Water twice a Week, if the Weather be good; but don't give them too much at each Time, leſt you thereby canker and rot their Roots.

About the Middle of *May*, or ſooner, (according as your Plants have thriven) their Runners will have grown ſo as to cruſh againſt the Glaſſes on every Side; therefore you ſhould place three Bricks under each Glaſs at right Angles, upon which the Glaſſes ſhould be ſet, ſo that there may be a Hollow under each of about two Inches, or leſs, which will be ſufficient to admit the Runners out; then you ſhould gently lead them from under the Glaſſes, putting each into its right Poſition, ſo that they may not croſs or intangle with each other; to prevent which, you ſhould have ſome ſmall forked Sticks, (ſuch as are commonly uſed in laying *Carnations*) with which you ſhould gently peg down each ſtrong Runner, which will prevent their being diſplaced by the Wind, or any other Accident. But you muſt obſerve, if the Nights prove cold, after they are let out from under the Glaſſes, to cover them with Mats; otherwiſe the Ends of the Shoots will ſuffer by the Cold, to the no ſmall Injury of the Plants: you muſt alſo obſerve to refreſh them with Water, (as before) but forbear all other pruning or handling them, for the Reaſons before laid down.

When the Vines have extended themſelves to the Sides of the Ridges, you ſhould dig up the Ground on each Side about two Feet wide, laying therein ſome old rotten Horſe-dung, covering it with the Earth, ſo as to raiſe it even with the Top of the Ridges, whereby they will be widen'd near four Feet; and ſo the Vines will have Room to run on each Side, without hanging down from the Ridges; and the old Dung which was laid on each Side will be of great Service to the Roots. After having made up the Ridges in this Manner, you muſt gently lay out the Shoots thereon, being careful that you do not bruiſe or break the Leaves with your Hands; and then ſet the Glaſſes on again over the Roots, where they may remain unremoved during the Continuance of the Plants: for after this, all the Water which is given to them muſt be gently ſprinkled all over the Plants; and it is no matter whether any of it falls cloſe to the Stems: But, on the contrary, the drier they are preſerved, the greater Vigour they will have; for the Roots, which are the chief Support of them, are at this Time at a much greater Diſtance from the Hole, and will receive the Benefit of the Water much better, when given all over the Top of the Ridges.

When your *Melons* begin to appear upon the Vines, if the Seaſon ſhould be very hot and dry, you ſhould pour down the Water in the Paths between the Ridges, which will ſoak in, and ſupply the Roots with Moiſture; and at that Seaſon, the Water which is given all over the Plants ſhould be but little, and given to them very gently, leſt by the Violence of the Water you injure the tender Fruit: But after they are grown as large as your Thumb, they will be almoſt out of Danger, tho' then it will be adviſeable to give them but gentle Refreſhings over the Vines; but this may be repeated two or three times a Week, according to the Heat of the Seaſon, obſerving always to do it in the Evening, that it may have Time to ſoak in before the Sun comes on to exhale the Moiſture. As to the pruning of them, I would (as I before ſaid) adviſe never to be *buſy* in that, ſince the more exact you are in that, the more likely you are to do hurt; therefore you need do no more than keep the Vines clear from Weeds, and train them in regular Order.

When the Fruit is about the Bigneſs of a Tennis-Ball, you ſhould place a thin Piece of Tile under each, to raiſe them from the Ground, otherwiſe they are very apt to rot, (eſpecially if the Seaſon ſhould prove moiſt) or, at leaſt to receive Damage on the Underſide; and when the *Melons* are full grown, you ſhould forbear watering them; and if the Weather be cold, you ſhould place Glaſſes over them, which will greatly accelerate their Ripening, and cauſe them to be better taſted: you ſhould alſo turn the Fruit two or three times as it is ripening, that every Part may be equally ripen'd; and in cutting them, you ſhould obſerve the Directions before laid down.

In ſaving the Seeds, you ſhould be careful to take them from ſuch Fruit as are well ripen'd, of a firm Fleſh, and well-taſted, ſuffering it to lie in the Pulp ſpread upon a Paper four or five Days before it be waſh'd out; then you muſt dry it, and put it up for Uſe, always obſerving to title each Sort, and add the Year it was ſaved.

The beſt Sorts for Frames, are the *Black Galloway*, and the *Small Portugal Melons*, which ripen early, and do not produce ſo ſtrong Vines as the larger Sorts, which require more Room than can be allow'd them in Frames.

There hath of late Years been a very great Variety of Melons, introduced into the Gardens of the Curious, which are much higher flavour'd, than moſt of the old Sorts; but they are not quite ſo hardy, nor do the Fruit of theſe new Sorts ever grow to ſo large Size as ſome of the old ones, which is the Reaſon of their not being more common. However, as they are much preferable for the Table, I ſhall juſt mention the Names of ſome of the principal Sorts, for the Satisfaction of the Curious.

1. The ZATTE MELON: This is a ſmall rough-coated Fruit, which ſeldom grows much larger than a Man's Fiſt, is very red within, and the Fleſh is very delicate.

2. The SUCADO MELON: This is larger than the former, of an oblong Shape, more wrought on the Outſide, is very red within, and the Fleſh is firm, and of a vinous Flavour.

3. The CANTALEUPT MELON: This is a longer Fruit than either of the former, is pretty much wrought on the Outſide, the Fleſh is not quite ſo red as of either of them, but is of a rich vinous Flavour.

4. The ROMANETTO MELON: This is a middle-ſized Fruit, of an oblong Shape; the outer Coat is greener than either of the former, and not very much wrought; the Fleſh is very red, and of a delicate Flavour.

Theſe Sorts are the beſt worth cultivating for private Families, who eſteem a Fruit for its delicate Flavour, more than for the Size: But thoſe who raiſe them to ſupply the Markets, muſt have regard to the Size of the Fruit, being paid for them according to their Magnitude. The Seeds of theſe Sorts are only to be procured from Perſons who are very careful to ſave them diſtinctly; for if they are purchaſed from the common Venders of Seeds, they are not much to be depended on.

Of late Years there has been a Method of raiſing the general Crop of Melons under oiled Paper, inſtead of Bell or Hand-Glaſſes; which has ſucceeded ſo well, as to be now very commonly practiſed in the Gardens near *London*. The Perſon who firſt practiſed this Method, was Mr. *John Howard* Gardener, at *St. Leonard's Hill* in *Windſor Foreſt*, who continued it for many Years with great Succeſs, and was not followed in it by any other Perſon, until his Son, who was Gardener to his Grace the *Duke of Chandos*, practiſed it at *Cannons*; and then it became more generally known, and has ſince been conſtantly practiſed by many Gardeners. But this Method being at preſent unknown to Perſons who reſide in the Country, I ſhall inſert it in this Place. The Manner of raiſing the Plants, as alſo of making the Ridges, being the ſame as for Hand-Glaſſes, I ſhall not repeat either, but proceed to give Directions for preparing the Papers. You muſt provide yourſelf with a Quantity of ſtrong Cap-paper, nine Sheets of which muſt be allowed to each Hole of Melons. Theſe nine Sheets of Paper muſt be joined together with Paſte (which when done will ſpread the Width of a common Mat which is uſed for Covering). When the Paſte is dry, the Paper ſhould be ſpread on a Board, or hung againſt a Wall, and with a Bruſh ſhould be rubbed over with Oil, which need be done but on one Side; for the Oil will ſink thro' the Paper, if it be only lightly bruſhed over; then the Papers ſhould hang out till they are dry, after which they may be uſed for covering your Melon-Plants. Theſe Papers ſhould be prepared, before you plant out your Plants into the Holes, that they may be ready to cover them, which may be performed in the following Manner; *viz.* After the Ridges are made, you muſt procure ſome ſmall Hoops, or ſlender Withies, which ſhould be thruſt into the Ground on each Side of the Ridge, and arched over in the ſame Manner as is practiſed for covering Flower-beds; then the Papers may be laid over the Hoops, *&c.* and faſtened down at each End with a Cord, or a few large Stones or Bricks laid upon their Ends, to prevent the Winds from blowing them off. Theſe Papers ſhould be kept cloſe over the Plants, while they are young, or in bad Weather; but when the Plants have obtained Strength, and the Weather is favourable, they ſhould be raiſed on one Side to admit Air to the Plants, and in ſoft Rains they ſhould be taken quite off, that the Plants may enjoy the Benefit thereof. Theſe Papers may continue over the Plants throughout the Seaſon, obſerving only to take them off in ſoft Rains, and admit Air under them in warm Weather to the Plants, as was before directed. The Plants will thrive much better under theſe than under Glaſſes; for the Rays of Light will be more equally admitted thro' the Paper when oiled, than thro' a Glaſs, which collects the Rays, and thereby occaſions too great a Heat in Summer under them, more than moſt Plants can endure. So that Plants under Glaſſes are ſubject to Danger, from the great Inequality of Heat; whereas thoſe under Papers enjoy a more equal Degree, and hereby the Plants are continued much longer in Vigour; as I have always obſerved thoſe under Papers in great Health, when thoſe under Glaſſes have been decayed, tho' they were in the ſame Situation, and under the ſame Management. The only Danger of theſe Plants miſcarrying is, when the Papers are kept too cloſe over them, which will cauſe the Plants to grow weak, and of a pale ſickly Complexion; whenever this is the Caſe, there cannot be much good Fruit expected from them.

Tho' I have directed the making of the Ridges after the ſame Manner as for Hand-Glaſſes, yet there are ſome Perſons who only dig Holes in the Ground at proper Diſtances, into each of which they put two Barrows-full of hot Dung, covering it over with the Earth taken out of the Holes, into which they plant their Melon-plants; then arch over each Hole with a few ſlender Wands, covering them with the Papers, and managing them as hath been directed; in which Method I have obſerved they have had a prodigious Crop of Melons, with a much leſs Expence than uſual.

N. B. Theſe oiled Papers will laſt one whole Seaſon very well; ſo that the Expence of Paper and Oil will amount to Three-pence Half-penny for each Hole.

Theſe Oil Papers have been uſed by ſeveral Perſons, to cover tender exotick Plants in Summer, with great Succeſs, as alſo to cover Beds of Cuttings of tender Plants, for which Purpoſe there is no other Covering ſo proper. They are alſo uſed to cover the Flowers of large Carnations, in order to ſcreen them from the violent Heat of the Sun, and to preſerve them dry, without which many of the largeſt Flowers would not blow to Advantage. The Method uſed by Mr. *Samuel Brewer* to cover his Flowers with oiled Paper, is, to make a Frame of Wire, juſt in the ſame Form as the Glaſs-covers, which are uſed for this Purpoſe, over which he paſtes the oiled Paper; which if carefully done, will laſt ſeveral Years, and are much preferable to Glaſſes.

MELOCACTUS, [ſo call'd of Μῆλον, a *Melon*, and Κάκτος, a *Thiſtle*, becauſe it reſembles a *Melon*: and it is alſo call'd *Echinomelocactus*, becauſe it reſembles a *Hedge-hog* by its Prickles.] Melon-Thiſtle.

The *Characters* are;

The whole Plant hath a ſingular Appearance, is very ſucculent, and hath many Angles, which are beſet with ſharp Thorns; the Flower conſiſts of one Leaf, is tubuloſe and Bell-ſhaped, divided into ſeveral Parts at the Top, and hath many Stamina or Threads; the Ovary becomes a ſoft fleſhy Fruit, containing many ſmall Seeds.

The *Species* are;

1. Melocactus *Indiæ Occidentalis. C. B. P.* The common or large Melon-Thiſtle, *commonly call'd* Turk-cap or Pope's-head in the *Weſt-Indies.*
2. Melocactus *Americana, minor. Boerh. Ind.* The leſſer Melon-Thiſtle, or ſmall Turk's-head.
3. Melocactus *Americanus major, ſpinis albis longiſſimis recurvis.* The greater *American* Melon-Thiſtle, with very long white crooked Spines.
4. Melocactus *Americanus major, ſtriis in ſpiram intortis, ſpinis brevibus aduncis.* Greater *American* Melon-Thiſtle, with ſpiral Ribs, and ſhort crooked Spines.
5. Melocactus *Americanus major, ſpinis tenuibus flaveſcentibus.* Greater Melon-Thiſtle, with ſlender yellowiſh Spines.
6. Melocactus *Mexicanus, ſpinis creberrimis corallinis latis & recurvis. Houſt.* Melon-Thiſtle of *Mexico*, with broad flat crooked Spines.

The two firſt Plants are Natives of the Rocks in the *Weſt-Indies*, where they are thruſt out from the Apertures thereof, and can receive but little Nouriſhment from the Soil; nor will they thrive when tranſplanted into another Situation, tho' it be in the ſame Degree of Heat, unleſs the Place be raiſed above the Level of the Ground with Stones and Rubbiſh.

The great Sort (which is very plenty in *Jamaica*, and the other Iſlands in the *Weſt-Indies*) is brought into *England* very often; but it rarely happens that they arrive here in perfect Health; for the People who bring them over, ſuppoſe they can't live without Moiſture, which they ſeldom fail to ſupply all the Plants they bring over with, whereby they are rotted and deſtroy'd; and altho' theſe Plants do not preſently ſhew the Damage they have ſuſtain'd in their Paſſage, yet they ſeldom continue long before they periſh: Therefore the beſt Method to bring them over, is to take them up intire from their Places of Growth, and pack them up in a large Box, with dry Hay or Straw, ſo that they may not wound each other in their Paſſage, obſerving to place them where neither Moiſture nor Vermin can come to them, in which Way they will arrive in perfect Health; but the Perſons who get them, ſhould never chuſe the oldeſt Plants, but rather ſuch as are young and thriving, which are the moſt likely to continue any Time with us.

But if they are brought over planted in Tubs, then the beſt Method is to fill the Tubs with Rubbiſh, and ſet the Plants therein, obſerving never to give them any Water during their Paſſage, nor ſuffer them to receive Wet, which will certainly damage them: and when they arrive in *England*, they ſhould immediately be taken out of the Tubs, and planted into Pots filled with Lime-Rubbiſh and Sea-ſand intermix'd, and the Pots plunged into a Hot-bed of Tanners-bark, to facilitate their taking Root: In which Bed they ſhould remain until the Beginning of *October*, when they muſt be removed into the Stove, obſerving to place them in the warmeſt Situation, and be very careful not to let them have the leaſt Moiſture during the Winter-ſeaſon, which will infallibly rot them. In the Spring of the Year, they may be removed out of the Stove into the Bark-bed again, at the ſame Seaſons when the *Anana's* are taken out, and ſhould be placed in ſuch a Frame where they will only require a little Air in very hot Weather, but ſhould not be water'd; for the Moiſture which ariſes from the Tanners-bark will be ſufficient for them.

This Plant is not very eaſy to increaſe in this Country, tho' I have ſeen ſome young ones that were produced from Seeds which ripen'd in *England:* Theſe Seeds were ſown upon a Pot of Lime-rubbiſh, and but gently cover'd with the ſame Mixture of Lime-rubbiſh and Sand, (as was before order'd for theſe Plants) and the Pots plunged into a Hot-bed of Tanners-bark, where the young ones began to appear in about ten Weeks after ſowing and by careful Management were preſerved: But theſe Plants being of very ſlow Growth, do not arrive to any Magnitude in leſs than four or five Years, which renders this Method very tedious, and as it is not a very ſure one, ſo it is ſeldom practiſed in *England.* I have alſo made Uſe of another Method, which has ſucceeded very well; *i. e.* when the Cap or Crown, which is produced on the Top of the Plant, has been injured, it occaſions the Plant to ſend out many Side-heads, ſeveral of which I have taken off, and planted in Pots fill'd with Lime-rubbiſh and Sea-ſand, plunging the Pots into a Hot-bed, and they have taken Root very well, and in one Year's Time have made very handſome Plants; but theſe Heads ſhould not be planted immediately after they are taken from the old ones; for the wounded Part will be apt to rot; therefore you ſhould lay them by in a warm Part of the Stove for about a Fortnight; in which Time the wounded Part will heal over, and they may then be planted without Danger: But you muſt obſerve to keep them very dry, otherwiſe they will rot in a ſhort Time.

The ſmaller Sort is not ſo common in *England*, which is occaſion'd by its being very rare in our *American* Settlements, this being originally brought from the *Spaniſh Weſt-Indies*, where are a great Number of other very ſtrange Sorts.

This is only propagated by Seed, which is produced in great Plenty every Year from old Plants. The Fruit of this Kind is not thruſt out from the Top of the Plant, as in the larger Sort, but is produced from the Hollows between the Protuberances of the Plant, and are preceded by a white Cottony Subſtance, which ſurrounds the Flowers. Theſe Fruit are nearly as large, and of the ſame Shape and Colour with thoſe of the large Sort, and are as full of Seeds.

Theſe Seeds muſt be ſown in the ſame Manner as the former, and the Plants preſerved both Winter and Summer in the ſame Situation, and ſhould have but little Moiſture in very hot Weather; tho' in Winter they muſt not have any Water given them; for at that Seaſon they are very apt to rot, if they receive any Moiſture.

Theſe Plants are preſerved with great Care by ſuch as are curious in Exoticks, they being of the moſt uncommon and wonderful Structure, greatly differing from any Thing in the Vegetable Kingdom, of *European* Growth, inſomuch that many Perſons at the firſt Sight of theſe Plants, have ſuppoſed them not natural Productions, but rather ſome artful Contrivance to amuſe People, until they have more maturely conſider'd their Parts.

The Fruit of both Sorts are eaten in the *Weſt-Indies*: They have a very grateful Acidity in their Taſte, which is extremely agreeable to the Inhabitants of thoſe warm Countries: But I don't know any farther Uſe of the Plants.

The third, fourth, and fifth Sorts I have received from the *Engliſh* Settlements in *America*, where I doubt not there are ſeveral other Varieties, if they were examined by Perſons ſkilful in Botany. Theſe are generally older before they put out their Caps on their Tops, than the common Sort; for I have had two of the Sorts five or ſix Years in *England*, which have increaſed in their Magnitude greatly ſince I received them; but neither of them has any Tendency to put out Caps, tho' ſome of the common Sort, not near ſo large, have produced large Caps, and have ripened their Fruit. So that I am in Doubt whether ſome of theſe Sorts ever produce Caps in the natural Places of their Growth; for they may produce their Fruit, either from the Sides of the Plant, as the ſmall *American* Sort doth, or round the Center of the Head, as I have ſeen ſome of them repreſented in Figures.

The ſixth Sort was brought from *Mexico*, by the late Dr. *William Houſtoun*; but being a long Time in the Paſſage, and the Plants receiving ſome Wet, they all of them were decayed before they arrived in *England*. This is one of the moſt ſtrange Plants of this Genus I ever ſaw; the Spines, which are produced very cloſely all over the Plant, are two Inches or more in Length, and near a Quarter of an Inch broad at their Baſe; are extremely ſtrong, and of a browniſh red Colour; theſe the Inhabitants of *Mexico* make uſe of to pick their Teeth, from whence they give the Name of *Viſnaga*, i. e. Tooth-pick, to theſe Plants.

As theſe Plants are eſteemed by the Curious, for their ſingular Structure being ſo very different from all the *European* Plants; ſo moſt People who have the Conveniency of Stoves to preſerve them, are extremely curious to obtain them from Abroad; but the Perſons who have the Care of bringing them, for want of Judgment, generally deſtroy them with Water, before they arrive in *England:* for altho' they often arrive in ſeeming Health, yet the Moiſture which they have imbibed in their Paſſage, will rot them in a little Time after they are planted. Therefore, whenever theſe Plants are brought over planted in Tubs, the beſt Way is to take them up as ſoon as they arrive, and ſet them upon the Flues in the Stove to dry; where (if they arrive early in the Summer) they may remain two Months before they are planted; but when they come late in the Year, they ſhould remain on the Flues all the Winter; and about the Beginning of *April*, they may be planted in *Lime-rubbiſh*, as is above directed; and theſe Plants will more certainly ſucceed, than thoſe which are planted ſoon after they arrive, as I have ſeveral Times experienced. Some of theſe Plants I have kept dry out of Earth, on the Flues or in ſome dry warm Part of the Stove, nine Months, and have then planted them, and they ſucceeded better than thoſe which were planted ſoon after I received them, tho' they were to Appearance not near ſo likely to live. So that if thoſe Gentlemen who bring over theſe Plants, would take them out of the Ground, and hang them up in a dry warm Part of the Ship, where they might not be bruiſed or eaten by Vermin; they will more certainly ſucceed, than thoſe Plants which are brought over in Tubs of Earth.

The ſmaller Melon Thiſtle, which was ſome Years ſince very rare in *England*, is now become pretty common in the Gardens of the Curious: for as they produce a great many Fruit annually, ſo they may be propagated in great Quantities by Seed; nay, if the Seeds are permitted to fall on the Earth, in the Pots where the old Plants are growing, the young Plants will come up in great Abundance, ſo that a Perſon may ſoon be ſtocked with them.

MELOCARDUUS. *Vide* Melocactus.

MELON. *Vide* Melo.

MELONGENA, Mad-Apple.

The *Characters* are;

The Flower conſiſts of one Leaf, ſhaped like a Wheel, and cut into many Segments: From the Flower-cup ariſes the Ovary, which becomes a fleſhy Fruit, full of Kidney-ſhaped Seeds.

The *Species* are;

1. MELONGENA *fructu oblongo violaceo. Tourn.* Mad-Apple, with an oblong Violet-colour'd Fruit.
2. MELONGENA *fructu oblongo albo. Tourn.* Mad-Apple, with an oblong white Fruit.
3. MELONGENA *ſpinoſa fructu rotundo croceo. Tourn.* Prickly Mad-Apple, with a round Saffron-colour'd Fruit.
4. MELONGENA *fructu rotundo, cum ſpinis violaceis. Tourn.* Mad-Apple, with a round Fruit, and Violet-coloured Prickles.

There are ſeveral other Varieties of this Plant, which differ in the Size, Form, or Colour of the Fruit, or in the Shape of their Leaves; but thoſe here méntion'd, are all that I have obſerv'd in the *Engliſh* Gardens.

Theſe Plants are greatly cultivated in the Gardens of *Italy*, *Spain*, and *Barbary*; in which Places the Inhabitants eat the Fruit of them boil'd with fat Fleſh, putting thereto ſome ſcraped Cheeſe, which they preſerve in Vinegar, Honey or Salt-pickle all Winter, to provoke a Venereal Appetite: But in Summer, when the Fruit is juſt ripe, they uſually gather them, and make them up into Puddings with ſeveral Sorts of Spices, and other Ingredients: Which Diſh the *Italians* are very fond of.

They are propagated by Seeds, which muſt be ſown upon a moderate Hot-bed in *March*; and when the Plants come up, they muſt be tranſplanted into another Hot-bed about four Inches aſunder, obſerving to water and ſhade them until they have taken Root: After which you muſt give them a great Share of Air when the Weather is warm, otherwiſe they will draw up very weak: They muſt alſo be frequently water'd, without which they will make but a very indifferent Progreſs: But when they are grown ſo ſtrong as to fill the Frame (which will be by the Middle of *May*) you muſt tranſplant them out into a rich Spot of Ground at two Feet Diſtance, obſerving to preſerve as much Earth to the Roots as poſſible when you take them up, otherwiſe they are ſubject to miſcarry. You muſt obſerve to water them plentifully until they have taken Root, after which they will require but very little Care more than to keep them clear from Weeds, and in very dry Weather to give them ſome Water.

About the Middle of *June*, the Fruit will appear; at which Time, if the Weather be very dry, you muſt often water them, which will cauſe the Fruit to grow very large, and increaſe their Number: Toward the latter End of *July* their Fruit will ripen, when you muſt preſerve the Seeds of each Kind ſeparate.

Theſe Plants are only preſerv'd as Curioſities in the *Engliſh* Gardens, the Fruit being never us'd in this Country, except by ſome *Italians* or *Spaniards*, who have been accuſtom'd to eat of them in their own Countries.

MELOPEPO; [this Plant is ſo call'd of μῆλον, an *Apple* or *Melon*, becauſe its Fruit comes near to the Size of a *Melon*; and *Pepo* a *Pompion*; becauſe it participates of the Nature of a *Pompion*] The Squaſh.

The *Characters* are;

It hath the whole Appearance of a Pompkin *or* Gourd; *from which this differs in its Fruit, which is roundiſh, fleſhy, ſtreaked, angular, and for the moſt Part divided into five Partitions, incloſing flat Seeds adhering to a ſpongy Placenta.*

The *Species* are;

1. MELOPEPO *compreſſus. C. B. P.* The common *or* flat Squaſh.
2. MELOPEPO *fructu maximo albo. Tourn.* The large white Squaſh, *commonly call'd*, The white flat Pumkin.
3. MELOPEPO *fructu citriformi. Tourn.* The Citron-ſhaped Squaſh.
4. MELOPEPO *verrucoſus. Tourn.* The warted Squaſh.
5. MELOPEPO *verrucoſus, fructu & ſemine albis. Tourn.* Warted Squaſh, with white Fruit and Seed.
6. MELOPEPO *flaveſcens, folio aſpero. Tourn.* Yellowiſh Squaſh, with a rough Leaf.

There are ſeveral other Varieties of this Plant in the *Weſt-Indies*, where they greatly abound, moſt of which are ſeminal Variations, and ſeldom continue long to produce the ſame Kinds from Seeds, at leaſt with us they never do continue three Years together the ſame, but do vary moſt extraordinarily; for the Seeds ſav'd from ſuch Plants which grew upright, and did not produce Runners (as the more ordinary Sorts) the ſucceeding Year, were as luxuriant as any of other Kinds, and the Fruit was of a different Shape from thoſe which the Seeds were taken from.

Theſe are all propagated by ſowing their Seeds in *March* upon a moderate Hot-bed; and when the Plants come up, they ſhould have a great Share of Air, otherwiſe they will draw up ſo weak, as to be good for little; You muſt alſo gently refreſh them with Water, as you ſhall find they require it. In *April* they muſt be tranſplanted out where they are deſigned to remain (which in *England* is moſt commonly upon old Dunghills, over which the Vines will ſpread, and produce a great Quantity of Fruit:) If you plant them in an open Spot of Ground, you ſhould dig Holes at about fourteen Feet ſquare, into each of which you ſhould lay a Barrow full of hot Dung, making a Hollow in the Middle to receive the Plants, which muſt be fill'd with good rich Earth; then cover the Dung all over, Top and Sides, with the Earth that came out of the Hole, placing a Glaſs over the Middle; in which Manner it ſhould remain until the Earth in the Holes begins to warm, (which is commonly in twenty-four Hours after making) when you muſt take them up out of the Seed-bed, and plant two of 'em into each Hole, obſerving to water and ſhade them until they have taken Root: After which you muſt let them have much free Air; and when they begin to ſend forth their Shoots, you muſt take off the Glaſſes and permit them to run, obſerving only to clear them from Weeds, and in very dry Weather to refreſh them now and then with a little Water.

In *July* theſe Plants will produce a great Quantity of Fruit, which ſome People are very fond of: Theſe they will gather while young, and boil them with Meat inſtead of Turnips: But notwithſtanding what ſome Perſons have advanc'd concerning the Goodneſs of this Fruit, yet, from ſeveral Trials which I have made, I could not bring my Palate to reliſh them, for they have a very great Flatulency in their Taſte, which is agreeable to very few Perſons: But in the *Weſt-Indies*, where there is a Scarcity of Garden Roots and Plants, theſe and many other Sorts are eſteemed Delicacies.

MELONRY, or MELON-GROUND, is an Apartment in the Kitchen-Garden for the Propagation of *Melons*.

This Spot of Ground ſhould be open to the South-Eaſt Sun, but ſhelter'd from the Weſt, North-Weſt, and North-Eaſt Winds, by Walls, Pales, or Hedges; it ſhould alſo be upon a dry Soil, for nothing is more injurious to theſe Plants than much Wet: And in the Spring it often proves very wet Weather; when if the Soil be very wet, there will be no making the Ridges until it is very late. You ſhould alſo contrive to place it as near to the Dung as poſſible, which will ſave a great deal of Labour in wheeling the Dung; and, if poſſible, you ſhould contrive to have a Pond of Water near it, which in very dry Weather will be very uſeful to water the *Melons*.

As to the Size of the Ground, that muſt be proportion'd to the Quantity of Ridges intended, which you may eaſily calculate by allowing eight Feet and a half for every Ridge, and the Holes placed at about three Feet aſunder; but it is the beſt Way to allow Room enough where you are not ſtraiten'd for it.

This Ground ſhould be incloſ'd with a Reed-Fence, and kept conſtantly lock'd up during the Time that the *Melons* are growing, for if they are expoſ'd to every Perſon that walks in the Garden (moſt of whom have a Curioſity to handle the Vines, and look after the Fruit) it will be of ill Conſequence, nothing being more injurious to theſe Plants than frequent tumbling or diſturbing their Leaves.

The common Practice in moſt Gentlemen's Gardens, is, to incloſe a Spot of Ground either with Walls or Pales, which they conſtantly appropriate to this Purpoſe: But this is by no means a good Method; for it rarely happens that theſe ſucceed well, longer than two Years in the ſame Place, unleſs the Soil be removed, and freſh brought in, which is very expenſive; therefore the beſt Way is, to have a ſufficient Parcel of Reeds made into Pannels, which may be annually moved from Place to Place, ſo that you need not continue your Ridges longer than one Year in the ſame Place. And if you have a Piece of Ground which is large enough to divide into four ſuch Places, the Fence may be every Year remov'd forward, till the whole has been occupy'd; after which you may return to the Spot where you began, which, by that Time, will be as good as freſh Earth: And hereby, without much Trouble, you may remove them every Year; for as one of the Sides will remain unremov'd every Time the Fence is carried forward, ſo the Labour will not be ſo great as if it were wholly remov'd to ſome Diſtance; and theſe Reed-Fences are much preferable to either Walls or Pales for this Purpoſe.

MENISPERMUM, Moon-ſeed.

The *Characters* are;

It hath a roſaceous Flower, conſiſting of ſeveral ſmall Leaves, which are placed round the Embryo in a circular Order. The Pointal, which is divided into three Parts at the Top, afterward becomes the Fruit or Berry, in which is included one flat Seed, which is, when ripe, hollowed like the Appearance of the Moon.

The *Species* are;

1. MENISPERMUM *Canadenſe ſcandens, hederaceo folio. Acad. Reg. Scien.* 1706. Climbing Canady Moon-ſeed, with an Ivy-leaf.
2. MENISPERMUM *Canadenſe ſcandens, umbilicato folio. Acad. Reg. Scien.* 1706. Climbing Canady Moon-ſeed, with an umbilicated Leaf.
3. MENISPERMUM *folio hederaceo. Hort. Elth.* Ivy-leaved Moon-ſeed.

The firſt and ſecond Sorts have been long Inhabitants of the *European* Gardens. Theſe produce flexible woody Shoots from their Roots, which twiſt round whatever Plants ſtand near them, and will grow to the Height of ten or twelve Feet, and produce their Flowers in Autumn, but they rarely perfect their Seed in this Country.

Theſe Plants are Natives of *Virginia*, and moſt of the Northern Parts of *America*, from whence they were many Years ſince brought into *Europe*, and were preſerved in the Green-houſes in Winter, as tender Plants; but of late Years they have been planted in the full Ground, where they endure the Winter's Cold extremely well without any Shelter. They may be eaſily propagated by the Suckers, which are produced in Plenty from their Roots: theſe ſhould be taken off with ſome Fibres adhering to them, in the Spring, before the Plants make new Shoots; and may be planted where they are deſigned to remain, obſerving to water them, if the Seaſon ſhould prove dry, until they have taken Root; after which Time they will require no farther Care, but to keep them clear from Weeds, and to ſupport them with Stakes, unleſs they are planted near Trees, round which they may faſten themſelves; for if they trail on the Ground, they will not thrive.

The third Sort was brought from *Carolina* by Mr. *Catesby*. This is a Plant of humbler Growth than either of the former, ſeldom riſing above four or five Feet high in this Country, and the Stems do not become woody. The Leaves are alſo much ſmaller than either of the other Sorts. This Plant will endure the Cold of ordinary Winters very well in the open Air, provided it is planted in a warm Soil, and a ſheltered Situation. It may be propagated by Suckers from the Root, as the two former Sorts, which are alſo produced in as great Plenty.

The two former Sorts were by Dr. *Plukenet* ranged amongſt the Ivies, from ſome Similitude in the outward Appearance of the Plants to the Ivy. So, from his Name, they were commonly called in the Gardens, Ivy with a bind-weed Leaf.

MENTHA, [Μίνθη, according to the Ancients, a *Goddeſs*, and alſo according to the Poets. The Ancients alſo gave it the Name of *Sweet-ſmelling*; and where this Word is found, this Plant is underſtood. *Mentha* is likewiſe ſo call'd of *Mens*, Lat. the *Mind*, becauſe this Plant ſtrengthens the Mind: It hath the ſame Smell and Taſte, and is much the ſame in all the Plants of this Genus] Mint.

The *Characters* are;

It is a verticillate Plant, with a labiated Flower conſiſting of one Leaf, whoſe Upper-lip is arched, and the Under-lip is divided into three Parts; but both of them are ſo cut, that the Flower ſeems to be divided into four Parts, the two Lips ſcarcely appearing; theſe Flowers are collected into thick Whorles in ſome Species; but in others they grow in a Spike; each Flower having four Seeds ſucceeding it, which are incloſ'd in the Flower-cup: To which may be added, It hath a creeping Root, and the whole Plant has a ſtrong aromatick or balſamick Scent.

The *Species* are;

1. MENTHA *anguſtifolia ſpicata. C. B. P.* Common Spik'd-mint, *uſually call'd* Spear-mint.
2. MENTHA *ſpicis brevioribus & habitioribus, foliis menthæ fuſcæ, ſapore fervido piperis. Raii Syn.* Pepper-mint.
3. MENTHA *ſylveſtris, folio longiore. C. B. P.* Long-leav'd Horſe-mint, *or* Mentaſtrum.
4. MENTHA *arvenſis verticillata hirſuta. J. B.* Water-mint with whorled Coronets, *commonly call'd* Water Calamint.
5. MENTHA *aquatica, ſeu Siſymbrium. J. B.* Water-mint.
6. MENTHA *Siſymbrium dicta, hirſuta, glomerulis ac foliis minoribus ac rotundioribus. Raii Syn.* Orange-mint.
7. MENTHA *ſpicata, folio variegato. C. B. P.* Spear-mint, with a variegated Leaf.
8. MENTHA *rotundifolia, paluſtris ſeu aquatica major, folio variegato. Tourn.* The Great Round-leaf'd Water-mint, with a variegated Leaf.
9. MENTHA *anguſtifolia ſpicata glabra, folio rugoſiore, odore graviore. Raii Syn.* Spear-mint, with a rugged Leaf, and ſtrong Scent.
10. MENTHA *Chalepenſis anguſtifolia, raro florens. Boerh. Ind.* Narrow-leav'd Aleppo-mint, which rarely flowers.

There are ſeveral other Sorts of *Mint*, which are preſerv'd in ſome curious Botanick Gardens, many of which are Natives of *England*; but as they are not cultivated for Uſe, ſo I ſhall omit them in this Place, thoſe above-mention'd being the Sorts which are commonly propagated for Kitchen or Medicinal Uſes.

The firſt Sort is the moſt commonly cultivated in the *Engliſh* Gardens, both for the Uſe of the Kitchen and Medicine; but the ſecond Sort is by ſome greatly eſteem'd for its Heat, to make a ſimple Water: This, at preſent, is not very common in the Gardens, but has been found growing wild in ſeveral Parts of *England*. The third Sort is alſo us'd in Medicine, but is rarely cultivated in Gardens, being found in great Plenty in ſeveral Places near *London*. The fourth and fifth Sorts are very common by the Sides of Ponds, and on moiſt Soils, in divers Parts of *England*, and are rarely cultivated in Gardens: Theſe are both us'd in Medicine, but the Markets are ſupply'd with them from the Fields. The ſeventh and eighth Sorts are preſerv'd in Gardens, for the Beauty of their variegated Leaves: As are the ninth and tenth Sorts, for their Oddneſs; the one having curl'd Leaves, and the other being very white, but ſeldom produces Flowers in *England*.

All the Sorts of *Mint* are eaſily propagated by parting the Roots in the Spring, or by planting Cuttings during any of the Summer Months; but ſhould have a moiſt Soil: And after planting, if the Seaſon ſhould prove dry, they muſt be often water'd, until they have taken Root; after which, they will require no farther Care but only to keep them clear from Weeds: They ſhould be planted in Beds about four Feet wide, allowing a Path two Feet wide, to go between the Beds to water, weed, and cut the Plants. The Diſtance they ſhoul be ſet is about four or five Inches, or more, becauſe they ſpread very much at their Roots; for which Reaſon the Bed ſhould not ſtand longer than three Years before you plant freſh for by that Time the Roots will be matted ſo cloſely, as t rot and decay each other, if permitted to ſtand longer. Ther are ſome People who are very fond of *Mint-Sallet* in Winte and Spring; in order to obtain which, they take up the Roo before *Chriſtmas*, and plant them upon a moderate Hot-be pretty cloſe, covering them with fine Earth about an Inc thick, and cover the Bed either with Mats, or Frames of Glaſs in theſe Beds the *Mint* will come up in a Month's Time, an be ſoon fit to cut for that Purpoſe.

Whe

When the Herb is cut for Medicinal Uſe, it ſhould be done in a very dry Seaſon, juſt when it is in Flower; for if it ſtand longer, it will not be near ſo handſome, nor ſo well-taſted; and if it be cut when it is wet, it will change black, and be little worth: This ſhould be hung up to dry in a ſhady Place, where it may remain until it be uſed.

If the Soil be good in which theſe Plants are to be ſet, they will afford three Crops every Spring: But after *July* they ſeldom prove good; therefore what Shoots are produc'd after that Time, ſhould be permitted to remain till *Michaelmas*, when you muſt cut them down cloſe; and after having clear'd the Beds from Weeds, you ſhould ſpread a little fine rich Earth all over them, which will greatly encourage the Roots againſt the ſucceeding Spring.

MENTHA CATARIA. *Vide* Cataria.

MENTZELIA.

The *Characters* are;

It hath roſe-ſhaped Flower, conſiſting of ſeveral Leaves, which are placed in a circular Order, and reſt on the Flower-cup, which afterwards becomes a membranaceous tubulous Fruit, containing many ſmall Seeds.

We know but one *Species* of this Plant at preſent; *(viz.)*

MENTZELIA *foliis & fructibus aſperis. Plum. Nov. Gen.* Mentzelia with rough Leaves and Fruit.

The Name was given to this Plant by Father *Plumier*, who diſcovered it in the *French* Settlements in *America*, in Honour to Dr. *Mentzelius*, who was Phyſician to the Elector of *Brandenburgh*, and who publiſhed an Index of Plants, in *Latin, Greek* and *High Dutch*.

This Plant grows plentifully in the Iſland of *Jamaica*, from whence the Seeds were ſent to *England* by the late Dr. *William Houſtoun*, which have ſucceeded in the Phyſic-Garden at *Chelſea*.

It is an annual Plant, which periſhes ſoon after the Seeds are ripe; ſo muſt be ſown on a Hot-bed early in the Spring, that the Plants may be brought forward early in the Seaſon, otherwiſe they will not produce ripe Seed in this Country. When the Plants are come up about an Inch high, they ſhould be each tranſplanted into a ſeparate Half-penny-pot, filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, being careful to ſhade them from the Sun, until they have taken new Root; after which Time they muſt be conſtantly watered every other Day, in warm Weather, and ſhould have freſh Air every Day admitted to them, in proportion to the Warmth of the Seaſon, and the Heat of the Bed in which they are plunged. In about ſix Weeks or two Months after tranſplanting, if the Plants have made a good Progreſs, they will have filled the Pots with their Roots; when they ſhould be ſhifted into larger Pots, which muſt be filled with light rich Earth, and then plunged into the Bark-bed in the Stove, that they may have Room to grow in Height, obſerving, as before, to water them duly, as alſo to admit freſh Air to them every Day in warm Weather; with which Management the Plants will riſe to the Height of three Feet, and will produce ripe Seeds the latter End of *Auguſt*, or the Beginning of *September*. Theſe Plants are cloſely beſet all over with ſmall crooked Spines, by which they will faſten themſelves to whatever touches them, ſo ſtrongly, that by a Perſon's going near them, they will ſtick to the Cloaths, and the Branches of the Plant will ſeparate and adhere to the Cloaths in like Manner as the Seeds of *Clivers* or *Gooſegraſs*.

MENYANTHES, *is* Trifolium Paluſtre, *or* Bog-bean.

This Plant is common upon boggy Places in divers Parts of *England*; but is never cultivated in Gardens, for which Reaſon I ſhall not trouble the Reader with any farther Account of it.

MERCURIALIS: [This Plant takes its Name from *Mercury*, becauſe the Ancients had a Notion, that the God *Mercury* brought this Plant into Uſe] Mercury.

The *Characters* are;

The Leaves are crenated, and grow by Pairs oppoſite; the Cup of the Flower conſiſts of one Leaf, which expands, and is cut into three Segments; theſe are Male and Female in different Plants; the Flowers of the Male grow in long Spikes, and conſiſt of many Stamina *and* Apices, *which are loaded with* Farina; *the Ovary of the Female Plant becomes a teſticulated Fruit, having a ſingle round Seed in each Cell.*

The *Species* are;

1. MERCURIALIS *teſticulata, ſive mas Dioſcoridis & Plinii. C. B. P.* The teſticulated Mercury, *vulgarly call'd*, The Male French Mercury.
2. MERCURIALIS *ſpicata, ſive fœmina Dioſcoridis & Plinii. C. B. P.* The ſpiked French Mercury.
3. MERCURIALIS *montana teſticulata. C. B. P.* Teſticulated Mountain Mercury, *commonly call'd* Dogs Mercury.
4. MERCURIALIS *montana ſpicata. C. B. P.* Spiked Mountain, *or* Dogs Mercury.
5. MERCURIALIS *fruticoſa incana mas. Boerh. Ind.* Hoary Shrubby Male Mercury.
6. MERCULIALIS *fruticoſa incana teſticulata. Tourn.* Shrubby hoary teſticulated Mercury.

The two firſt Sorts are annual Plants, which grow wild in divers Parts of *England*, and are rarely propagated in Gardens: The Seeds thereof being ſown, produce the two Sorts promiſcuouſly, and are both gather'd indifferently for Medicinal Uſe. Theſe Seeds ſhould be ſown as ſoon as they are ripe by thoſe who would cultivate it: They will grow upon any Soil or Situation.

The third and fourth Sorts grow wild in ſhady Lanes in divers Parts of *England*, where they ſpread greatly at the Roots: Theſe are never us'd in Medicine.

The fifth and ſixth Sorts are not Natives of this Country, but are preſerv'd in curious Botanick Gardens for Variety: Theſe may be propagated by ſowing the Seeds ſoon after they are ripe in a Bed of freſh Earth, where, if the Seeds are good, the Plants will come up the ſucceeding Spring, and endure the Cold of our ordinary Winters very well: But if the Plants from which the Seeds are taken, have not had ſome of the Male Plants, growing amongſt them, the Seeds will not grow, as I have ſeveral times experienc'd.

MESPILUS; [Μέσπιλος] The Medlar.

The *Characters* are;

The Leaves are either whole, and ſhap'd like thoſe of the Laurel, *as in the manur'd Sorts, or laciniated, as in the wild Sorts; the Flower conſiſts of five Leaves, which expand in Form of a* Roſe; *the Fruit is umbilicated, and are not eatable till they decay, and have for the moſt part five hard Seeds in each.*

The *Species* are;

1. MESPILUS *Germanica, folio laurino non ſerrato, ſive Meſpilus ſylveſtris. C. B. P.* The Common Medlar, *commonly call'd*, The Nottingham Medlar.
2. MESPILUS *folio laurino, major. C. B. P.* The large Dutch Medlar.
3. MESPILUS *apii folio, ſylveſtris ſpinoſa, ſive oxyacantha. C. B. P.* The common Hawthorn.
4. MESPILUS *ſpinoſa, ſive oxyacantha, flore pleno. Tourn.* The Double-flowering Hawthorn.
5. MESPILUS *apii folio laciniato. C. B. P.* The Azarola *or* Neapolitan Medlar.
6. MESPILUS *ſpinoſa, pyri folio. H. L.* The Pyracantha *or* Evergreen Thorn.
7. MESPILUS *ſeu ſpina acuta, biflora Britannica. Park. Theat.* The Glaſtenbury Thorn.
8. MESPILUS *ſpinoſa, ſive oxyacantha Virginiana. H. L.* The Cockſpur or *Virginian* Hawthorn.
9. MESPILUS *aculeata pyrifolia denticulata ſplendens, fructu inſigni rutilo Virginienſis. Pluk. Phyt.* The Virginian Medlar, with ſhining Leaves, and very red Fruit, *commonly call'd* The Virginian Azarol with red Fruit.
10. MESPILUS *Virginiana, apii folio, vulgari ſimilis major, grandioribus ſpinis. Pluk. Phyt.* Virginian Hawthorn, with long ſtrong Thorns.
11. MESPILUS *prunifolia Virginiana non ſpinoſa, fructu nigricante. Pluk. Phyt.* Virginian Hawthorn, with a Plum-leaf and black Fruit.
12. MESPILUS *folio ſubrotundo, fructu rubro. Tourn.* The Dwarf Medlar, with red Fruit.
13. MESPILUS, *folio rotundiore, fructu nigro ſubdulci. Tourn.* Dwarf Medlar, with black Fruit.
14. MESPILUS *apii folio, ſylveſtris ſpinoſa, ſive oxyacantha, fructu albo. Cat. Plant. Hort.* The common Hawthorn, with white Fruit.
15. MESPILUS *Americana non ſpinoſa, fructu luteo.* The American Haw, with yellow Fruit.

The firſt of theſe *Medlars* was formerly more common in the Gardens and Nurſeries than at preſent, for ſince the *Dutch Medlar* has been introduc'd, it hath obtain'd the Preference, the Fruit of this being much larger and better flavour'd than the old one, which hath occaſion'd their being cultivated in greater Plenty.

Both theſe Sorts may be propagated by budding or grafting 'em upon the *Hawthorn*, or the *Pear-ſtock*, upon either of which they will take very well ; and may be afterwards tranſplanted into the Fruit-Garden, either in Standards or train'd againſt an Eſpalier, in both which Methods they will ſucceed very well ; but if the larger Sort be train'd on an Eſpalier, the Fruit will be much larger : But you muſt be careful in pruning, not to ſhorten their bearing Branches, for the Fruit being, for the moſt part, produc'd at the Extremity thereof ; if they are ſhorten'd, it will be cut away.

Theſe Plants will grow upon almoſt any Soil ; but the Fruit will be much larger upon a ſtrong Soil, rather moiſt than dry ; though upon a middling Soil they are generally beſt flavour'd.

Theſe Fruits are permitted to remain upon the Trees till *October*, when they will begin to fall ; at which time they muſt be gather'd, when dry, and laid by in a dry Place, until they become ſoft, and begin to decay, which is commonly about a Month after they are gather'd ; when they will be fit to be eaten ; before which they are ſo very harſh, that it is almoſt impoſſible to eat them.

The third Sort is ſo very common in *England*, that it would be to little Purpoſe to ſpend much Time in treating of it, ſince the great Uſe to which it is apply'd in *England*, is to make Fences, the manner of doing which is already deſcribed under the Article of *Fences* and *Hedges* ; but I would only mention in this Place, that there are two or three Varieties of this Plant, commonly obſerved in the Hedges near *London*, which differ in the Size of their Leaves and Fruit ; but that Sort which produces the ſmalleſt Leaves is the beſt worth cultivating for Hedges, becauſe their Branches always grow cloſe together, ſo that the Hedge will clip much cloſer, and appear more beautiful : for it is a common Obſervation, That the Branches of all Sorts of Trees grow in a proportionable Diſtance to the Size of their Leaves.

The fourth Sort is a Variety of the third, from which it differs in having fair double Flowers. This is propagated by being budded or grafted upon the common Sort, and may be train'd up with regular Stems to the Height of twelve or fourteen Feet, and when planted in Wilderneſſes or other Plantations of Trees, being intermix'd with other flowering Trees of the ſame Growth, makes a very fine Appearance, during the Seaſon of its Flowering, which is commonly moſt part of *May* ; the Flowers being produced in large Cluſters, as in the common Sort, but are very double : This Tree is pretty common in the Nurſeries near *London*.

The *Azarola* or *Neapolitan Medlar*, has been introduced from *Italy*, where the Fruit is greatly eſteemed. This is alſo propagated by budding or grafting it upon Stocks of the common *Hawthorn*, and ſhould be tranſplanted into a moiſt Soil and a warm Situation, where it will produce great Quantities of Fruit annually in *England*, which are ſhap'd like thoſe of the common *Hawthorn*, but much larger, and muſt be preſerv'd till they begin to decay before they are eaten, as the common *Medlar*.

I have obſerv'd theſe Trees in many Places planted againſt warm Walls, as ſuppoſing them too tender to produce Fruit in this Climate, without ſuch Aſſiſtance ; which is a very great Miſtake, for I have ſeen much more Fruit upon Standard-Trees than were upon thoſe againſt Walls, and they ripen'd well and were better taſted.

The *Pyracantha* or *Evergreen Thorn*, was formerly in greater Eſteem than at preſent ; it is commonly planted againſt Walls or Buildings, where it affords an agreeable Proſpect in Winter, (eſpecially if it has Plenty of Fruit) the Fruit being at that Seaſon of a beautiful red Colour, and are commonly produced in very large Cluſters, which, together with its evergreen Leaves, renders it worthy of a Place in every good Garden. But in order to have Fruit upon every Part of the Tree, in which its greateſt Beauty conſiſts, there ſhould always be a Succeſſion of young Branches train'd in ; for the Fruit is always produced upon the ſecond and third Years Wood ; and all thoſe Branches which are older, never produce any : for want of rightly obſerving this Method, moſt of the Trees of this Kind ſeldom have any Fruit but toward their extreme Parts ; which is one Reaſon theſe Trees have been ſo much neglected of late Years.

The Branches of this Tree are very flexible, ſo that it cannot be train'd up to a Standard, but muſt always have the Aſſiſtance of a Wall, or ſome other Building, to ſupport it. It is very hardy, and will grow in almoſt any Soil or Situation ; but it agrees beſt with a dry Soil, in which it will always produce a greater quantity of Fruit.

This may be propagated by laying down the tender Shoots, which are commonly two Years before they will be rooted enough to tranſplant ; (but notwithſtanding this, it is a more expeditious Method than to raiſe them from Seeds, which rarely come up until the ſecond Year, and are but of ſlow Growth the two ſucceeding Years) then they may be either planted where they are to remain, or into a Nurſery for two or three Years, where you may train them, according to the Places where they are deſigned to be planted. It is commonly three Years after they are planted out, before they begin to produce Fruit.

The *Glaſtenbury Thorn* is preſerved in many Gardens as a Curioſity : this often produces ſome Bunches of Flowers in Winter, and afterwards flowers again at the Seaſon with the common Sort ; but doth in no other reſpect differ from the common *Hawthorn* : the fabulous Story of its budding on *Chriſtmas-day* in the Morning, flowering at Noon, and decaying at Night, is now with good Reaſon disbelieved ; for altho' it may ſometimes happen, that there may be ſome Bunches of Flowers open on that Day, yet for the moſt part it is later in the Year before they appear ; but this in a great meaſure depends on the mildneſs of the Seaſon. This Sort may be propagated by budding or grafting it upon the common *Hawthorn*, and ſhould be planted in a warm Situation, which will greatly promote the Flowering in the Winter ; for if they are too much expoſed to cold Winds, the Flower-buds will decay without opening, tho' in other reſpects the Plant is equally as hardy as the common Sort, and may be treated in the ſame Manner.

The *Cockſpur Hawthorn* is of larger Growth than any of the former, and is very hardy : this may be propagated by ſowing the Seeds, in the ſame Manner as the common *Hawthorn*, and they commonly abide in the Ground till the ſecond Year, as they do ; therefore the moſt expeditious Way to increaſe this Plant is to bud or graft it upon the common *Hawthorn* ; tho' I muſt confeſs, that the Trees thus propagated will not arrive to the Magnitude as thoſe generally do which are propagated from Seeds, but will produce Fruit much ſooner ; but where a Perſon intends to have them in Perfection, they ſhould always be propagated from Seeds. This Sort will grow to the Height of eighteen or twenty Feet, and may be train'd up with regular Stems and Heads, and when planted amongſt other Trees of the ſame Growth, they make an agreeable Variety ; for in the Spring, when they are in Bloſſom, they are very pleaſing, the Flowers being very large, and are produced in great Bunches at the Extremity of their Branches ; and in Autumn, when the Fruit is ripe, which is very large, and grows in great Cluſters, they have a beautiful Appearance, and are eſteem'd very good Feed for Deer.

The ninth, tenth, and eleventh Sorts were brought from *Virginia* ſeveral Years ſince, and are preſerved as Curioſities, by ſuch Perſons as are Lovers of Trees. Theſe may be propagated from Seeds, as the other Sorts, or by budding or grafting them upon the common *Hawthorn* ; and may afterwards be tranſplanted into Wilderneſs Quarters amongſt other Trees of the ſame Growth, where they will afford an agreeable Variety.

The ninth Sort will grow larger than the other two, and if raiſed from Seeds, will equal the *Cockſpur Hawthorn* ; and the Flowers and Fruit are full as large as thoſe ; ſo that it is very proper to be intermix'd therewith.

The tenth and eleventh Sorts commonly grow to the Size of our common *Hawthorn*, with which they may be intermix'd, for Variety, in Wilderneſs Plantations. The Fruit of theſe two Kinds are hardly ſo large as thoſe of the common *Hawthorn* ; but whether any of theſe Fruits are eatable, I don't at preſent know ; tho' I believe they are much the ſame as the common Sort.

The fourteenth Sort is a Variety of the common *Hawthorn*, which was obſerved ſome Years ſince in *Hertfordſhire* ; but whether the Seeds of this Kind will produce the ſame again, is what I can't at preſent determine : however, it may be propagated by budding or grafting it upon the common *Hawthorn*, which is the only ſure Method to preſerve the Variety ; tho' there is nothing more in it, than that it is uncommon.

The fifteenth Sort has been lately introduced among us from *America* : this is different from the other Sorts in the Shape of the Leaves, and hath no Thorns upon the Branches ; but whether the Fruit will continue of the ſame Colour as the Original, can't as yet be determined ; ſince there are no Plants in *England* large enough to produce Fruit, that I know of. This may be propagated by budding or grafting it upon the common *Hawthorn*, and is worthy of a Place in all curious Collections of Trees.

The twelfth and thirteenth Sorts are of humbler Growth, ſeldom riſing above five or ſix Feet high, and are proper to intermix with Shrubs of the ſame Growth, where, by the Variety of their woolly Leaves, together with their Flowers and Fruit, in their Seaſons, they add greatly to the Variety of ſuch Plantations: they may be eaſily propagated by laying down their tender Branches, which, in one Year, will be rooted ſufficiently to tranſplant; when they may be placed where they are to remain, or planted into a Nurſery, and train'd up to regular Heads; by which Method they will be leſs liable to miſcarry, than if they were placed to remain in the Wilderneſs immediately.

The twelfth Sort produces great Quantities of Suckers from the Roots, which may be taken off in the Spring, and tranſplanted into a Nurſery two or three Years, until they have acquired Strength enough to tranſplant for good where they are to remain; by which Method they may be greatly increaſed: but the Plants thus raiſed will be more ſubject to produce a great number of Suckers from their Roots, which, if not yearly taken off, will grow up into a Confuſion, and ſtarve the old ones.

They produce their Flowers in *April* and *May*, and their Fruits are commonly ripe in *Auguſt*; but theſe are of no Uſe, except to propagate the Plants; which being a tedious Method, and the Layers taking Root ſo freely, renders it not worth practiſing; tho' it may happen that ſome Varieties may be obtain'd this Way, as is often found in many other Trees and Shrubs.

METHONICA, the Superb Lily; *vulgo.*

The *Characters* are;

It hath a fleſhy Root in Form of a ſtrait Ruler, which is venomous: The Stalk is climbing: The Leaves grow alternately, and ſhaped like thoſe of the Lily, *but have a Claſper at the End: The Flower is naked, conſiſting of ſix Leaves, which are elegantly ſinuated, feather'd, and reflex'd back, with ſix* Stamina, *(or Threads); in the Center of which is the Ovary, which becomes an oval Fruit, divided into three Cells, containing ſeveral round Seeds.*

There is but one *Species* of this Plant, at preſent known which is;

METHONICA *Malabarorum. H. L. Malabar* Methonica, or the Superb Lily of *Ceylon*.

This beautiful Plant is propagated by parting the Roots in *Auguſt* (when the green Leaves are decay'd); which ſhould be planted into Pots fill'd with light ſandy Earth, and may be expoſed to the open Air for about a Fortnight or three Weeks after, placing the Pots where they may have the Morning Sun till Eleven o' Clock; and if the Seaſon ſhould prove very dry, you muſt now and then gently refreſh them with Water; but you muſt avoid giving them too much, (eſpecially while the Roots are unactive) which will rot them in a ſhort Time.

Toward the End of *Auguſt* or the Beginning of *September*, you muſt remove the Pots into the Stove, placing them where they may have free Air, but ſo as to have a warm Situation; obſerving, as was before directed, to refreſh them gently with Water, but not to give them much until they appear above Ground, which is commonly in *November*, provided they have Warmth enough, otherwiſe they will not come up till after *Chriſtmas*: When the Leaves begin to appear above Ground, you muſt increaſe the Quantity of Water before given them, and place a Stick down by the Root, to which the Stem ſhould be faſten'd, to ſupport it, otherwiſe it will trail upon the Ground: You ſhould alſo obſerve to place the Pots ſo that they may not ſtand too near any large growing Plants, which may hang over them, whereby theſe Plants will be drawn up, which will prevent their flowering; but they muſt, at this Seaſon, be kept pretty warm, in order to encourage them to flower. The Heat with which they thrive beſt, is about ten Degrees above temperate, (as mark'd on Mr. *Fowler's Botanical Thermometers*) but you muſt never let them have a leſs than temperate Heat, leſt the Roots ſhould periſh.

The Off-ſets taken from the old Roots are commonly two or three Years before they flower; during which Time they ſhould not be tranſplanted, but the Earth in the upper Part of the Pots ſhould be taken out, and freſh put in every Year, to encourage the Roots; being very careful in doing this not to injure or diſturb the ſame. In *July* and *Auguſt* the Pots may be expoſed to the open Air, if the Seaſon be warm; but all the other Part of the Year they muſt be continued in the Stove.

MEUM, [of Μεῖον, *leſs*, becauſe the Leaves of this Plant are very ſmall] Spignel.

The *Characters* are;

It is an umbelliferous Plant, with very narrow Leaves: The Seeds are large, oblong, and ſtriated: To which may be added, it hath a perennial Root.

This Plant is propagated in the *Phyſick-Gardens*, for Medicinal Uſe; but is very ſeldom found in other Gardens. It may be propagated by Seeds, which ſhould be ſown in Autumn, ſoon after they are ripe; and in the Spring the Plants will appear, when they ſhould be carefully clear'd from Weeds; and in very dry Weather muſt be refreſh'd with Water. In this Place the Plants may remain until the Autumn following, when they may be tranſplanted into a ſhady Border, about a Foot aſunder, where they may remain for Uſe. They may alſo be propagated by parting their Roots in Autumn, which is the moſt expeditious Method.

MEZEREON. *Vide* Thymelea.

MICROSCOPE, a Dioptrical Inſtrument, by means of which, very minute or ſmall Objects are repreſented very large, and capable of being view'd very diſtinctly, according to the Laws of Refraction.

This Inſtrument may be of ſingular Uſe to a curious Inquirer into the Operation of Vegetative Nature, by viewing nicely the ſeveral minute Veſſels and Parts of Vegetables, in order to diſcover their various Uſes, and how the Buſineſs of Vegetation is carried on.

MILDEW, is a Diſeaſe that happens to Plants, and is cauſed by a dewy Moiſture which falls on them, and continuing, for want of the Sun's Heat, to draw it up, by its Acrimony corrodes, gnaws, and ſpoils the inmoſt Subſtance of the Plant, and hinders the Circulation of the nutritive Sap, upon which the Leaves begin to fade, and the Bloſſoms and Fruit are much prejudiced. Or,

Mildew is rather a concrete Subſtance, which exſudes thro' the Pores of the Leaves.

What the Gardeners commonly call *Mildew*, is an Inſect, which is frequently found in great Plenty, preying upon this Exſudation.

Others ſay, That *Mildew* is a thick clammy Vapour, exhaled in the Spring and Summer from Plants, Bloſſoms, and even the Earth itſelf, in cloſe ſtill Weather, where there is neither Sun enough to draw it upwards to any conſiderable Height, nor Wind of Force ſtrong enough to diſperſe it; and that, hanging in the lower Regions, when the Cold of the Evening comes on, it condenſes and falls on Plants, and with its thick clammy Subſtance ſtops the Pores, and by that means prevents Perſpiration, and hinders the Sap from aſcending to nouriſh the Flowers, Shoots, *&c.*

Others ſay, That *Mildew* is a corroſive or nipping *Dew*, proceeding from the Vapours that are exhaled by the Earth, which being drawn up, and falling down again on the tender opening Buds, infects them by its Acrimony, and hinders the Circulation of the nutritious Sap in the proper Veſſels; upon which the Leaves begin to fade, and the Bloſſoms and Fruit receive a very great Prejudice.

Some make this Obſervation, That the Places moſt liable to *Mildew* are incloſed Grounds and Vallies, and thoſe that lie tending to the Eaſt; and the Reaſons that they give why thoſe Grounds which lie from the Horizon to the Eaſt are moſt ſubject to *Mildew* and *Blaſtings*, may be by the Sun's attracting thoſe Vapours towards it, after the Manner that a great Fire in a Room draws the Air to it: So the Sun having ſet theſe in Motion, and not having Strength enough to draw them into the middle Region, to form them into a Cloud, he does yet draw them till he is below our Horizon, and then theſe *Dews* tend to the Earth, from whence they were exhaled, and in Motion to the Weſt, do, as it were, fall upon that Ground which lies Eaſtward, at right Angles, and therefore is moſt offenſive to them.

But I take the true Cauſe of the *Mildew* appearing moſt upon Plants which are expoſed to the Eaſt, to proceed from a dry Temperature in the Air when the Wind blows from that Point, which ſtops the Pores of Plants, and prevents their Perſpiration, whereby the Juices of the Plants are concreted upon the Surface of their Leaves, which being of a ſweetiſh Nature, Inſects are inticed thereto, where finding proper Nutriment, they depoſite their Eggs, and multiply ſo faſt as to cover the whole Surfaces of Plants, and by their corroding the Veſſels, prevent the Motions of their Sap; and it is very probable, that the Excrements of theſe Inſects may enter the Veſſels of Plants, and by mixing with their Juices may ſpread the Infection all over them: For it is obſervable, that whenever a Tree has been greatly affected by this *Mildew*, it ſeldom recovers it in two or three Years, and many Times, never is intirely clear from it after.

Others ſuppoſe, that the Reaſon why Vallies afford more Moiſture than Hills, is becauſe of the *Dew* which is attracted from the Earth and Herbs as before; and that they do afford more Moiſture than Hills (they ſay) is often ſeen by the Miſts, which are more frequent on them than on Hills: This being drawn by the Sun in the Day-time, and wanting Wind to aſſiſt its Motion, hangs in the lower Region, and when the Sun ſets, it falls upon the Plants with its thick clammy Subſtance, and hinders the Sap of the Plant or Tree from aſcending to nouriſh its Flowers or Shoots in thoſe whoſe Bark is tender and young, and the Pores open with the Heat of the Seaſon.

This *Dew* has been obſerved in the great-leav'd *Cherries*, ſuch as the *Black Heart*, the *White Heart*, &c. to fall upon them at the Top, juſt at the Beginning of the Midſummer-ſhoot, which has ſo ſtopp'd the Shoot that it has ſhot forth in other Places below; and that on the Top of theſe Shoots there have been many ſmall Flies feeding on this *Dew*, and that it may plainly be ſeen and taſted on the Leaves of Oak and Maple.

Some are of Opinion, that *Mildews* and *Blights* are the ſame Thing: But others again, that *Mildew* is quite another Thing than *Blaſtings*. They ſay, *Mildews* are cauſed from the Condenſation of a fat and moiſt Exhalation in a hot and dry Summer, from the Bloſſoms and Vegetables of the Earth, and alſo from the Earth itſelf, which is condenſed into a fat glutinous Matter by the Coolneſs and Serenity of the Air, and falls down on the Earth again; Part of which reſts upon the Leaves of the Oak and other Trees, whoſe Leaves are ſmooth, and for that Reaſon do not ſo eaſily admit the Moiſture into them, as the Elm and other rougher Leaves do.

Other Parts of *Mildew* reſt upon the Ears and Stalks of *Wheat*, beſpotting the ſame with a different Colour from what is natural, being of a glutinous Subſtance, by the Heat of the Sun, and binds up ſo cloſe the tender Ears of *Wheat*, that it prevents the Growth, and occaſions it to be very light in the Harveſt.

Some are of Opinion, that *Mildews* are the principal Food of *Bees*, it being ſweet, and eaſily convertible into Honey.

MILIUM, [ſo call'd of *Mille*, Lat. a *Thouſand*, becauſe of the Multitude of its Grains] Millet.

The *Characters* are;

It hath a looſe divided Panicle; and each ſingle Flower hath a Calyx, conſiſting of two Leaves, which are inſtead of Petals, to protect the Stamina *and* Piſtillum *of the Flower, which afterwards becomes an oval ſhining Seed.*

The *Species* are;

1. **Milium** *ſemine luteo. C. B. P.* Yellow *or* common Millet.

2. **Milium** *ſemine albo. C. B. P.* Millet, with a white Seed.

3. **Milium** *ſemine nigro. C. B. P.* Millet, with a black Seed.

4. **Milium** *arundinaceum, ſubrotundo ſemine, Sorgo nominatum. C. B. P.* Reed-like Millet, with roundiſh Seeds, *commonly call'd* Sorgo *or* Guiney Corn.

There are ſome other Varieties of theſe Plants, which chiefly differ in the Colour of their Seeds, which will be to little Purpoſe to enumerate in this Place, thoſe here mention'd being the principal Sorts which I have obſerved growing in *England*.

The three firſt Sorts are Varieties of each other, and only differ in the Colour of their Seeds; which Difference will ariſe from the ſame Seeds very often; but the Yellow is always preferr'd, tho' the White is no Way inferior to it; but the Black Sort is eſteem'd little worth.

Theſe Plants were originally brought from the Eaſtern Countries, where they are ſtill greatly cultivated, from whence we are furniſhed annually with this Grain, which is by many Perſons greatly eſteem'd for Puddings, *&c.* Theſe are never cultivated in *England*, but by Way of Curioſity in ſmall Gardens, where the Seeds do generally ripen very well.

They muſt be ſown the Beginning of *April*, upon a warm dry Soil, but not too thick, becauſe theſe Plants divide into ſeveral Branches, and ſhould have much Room; and when they come up, they ſhould be clear'd from Weeds, after which they will, in a ſhort Time, get the better of them, and prevent their future Growth. In *Auguſt* theſe Seeds will ripen, when it muſt be cut down, and beaten out, as is practiſed for other Grain.

The *Guiney Corn* ariſes commonly to be ten or twelve Feet high, and has jointed Stalks like the Reed; upon the Tops of which the Panicles are produced, which are very large, as are alſo the Grains. This Sort will come up very well, if ſown as the former, but ſeldom perfects its Seeds with us, except the Seaſon be very warm.

MILLEFOLIUM, [ſo call'd, as if the Leaves had a thouſand Inciſions. *Pliny* relates, that *Achilles* having been inſtructed by *Chiron* in Phyſick and the Art of curing Wounds, cured *Telephus*, wounded by his own Sword, with this Plant; and hence it was call'd *Achillea*. It is alſo call'd *Stratiotes*, of Στρατὸς, an *Army*, becauſe this Plant is uſeful in curing the Wounds of Soldiers in an Army] Yarrow, Milfoil, *or* Noſe-bleed.

There are ſeveral Sorts of this Plant, which are cultivated in Botanick Gardens for Variety; but as they are rarely propagated for Uſe, I ſhall paſs them over without naming them, and only obſerve, that the common Sort, which grows in great Plenty upon dry Banks, in moſt Parts of *England*, is that which is order'd for Medicinal Uſe.

MILLERIA.

The *Characters* are;

It hath a compound Flower, conſiſting of ſeveral Florets, and one half Floret, contained in one common Flower-cup; but theſe Florets are barren, and the half Floret, which is fruitful, is ſucceeded by one Seed, which is ſurrounded by the Flower-cup.

The *Species* are;

1. **Milleria** *annua erecta major, foliis conjugatis, floribus ſpicatis luteis. Houſt.* Greater upright annual Milleria, with Leaves growing oppoſite, and yellow Flowers growing in a Spike.

2. **Milleria** *annua erecta minor, foliis parietariæ, floribus ex foliorum alis. Houſt.* Leſſer upright annual Milleria, with pellitory Leaves, and the Flowers growing from the Wings of the Leaves.

3. **Milleria** *annua erecta ramoſior, foliis maculatis, profundius ſerratis. Martyn. Cent.* 1. Upright branching annual Milleria, with ſpotted Leaves, which are deeply ſawed.

4. **Milleria** *annua erecta minor, folio parietariæ longiori, floribus ex foliorum alis.* Leſſer upright annual Milleria, with a longer pellitory Leaf, and the Flowers growing from the Wings of the Leaves.

The two firſt Sorts were diſcovered by the late Dr. *William Houſtoun* at *Campechy* in the Year 1731, who conſtituted this Genus, on finding the Characters differing from all the Genus's which were before eſtabliſhed. The Seeds of both theſe Sorts he ſent to ſeveral curious Perſons in *England* and *Holland*, where they have ſucceeded very well.

The other two Sorts were diſcovered by Mr. *Robert Millar*, Surgeon, at *Campechy* in the Year 1734, from whence he ſent their Seeds into *England*, where they have alſo ſucceeded very well. The third Sort nearly reſembles the firſt in its Leaves, Flowers and Growth; but branches a little more than that doth, and the Leaves are ſpotted with Black; the Flowers alſo are a little larger. The fourth Sort, which is ſomewhat like the ſecond, grows taller, and doth not branch from the Bottom as the ſecond doth; the Leaves are alſo much longer, but there appears no Difference in their Flowers.

The Seeds of theſe Plants ſhould be ſown early in th Spring, on a moderate Hot-bed; and when the Plants ar come up about two Inches, they ſhould be each tranſplante into a ſeparate Pot, filled with light rich Earth, and the plunged into a moderate Hot-bed of Tanners Bark, bein careful to ſhade them from the Sun until they have taken Root as alſo to water them frequently. After the Plants are roote they ſhould have a large Share of free Air admitted to them by raiſing of the Glaſſes of the Hot-bed every Day when th Weather is fair; and they muſt be conſtantly watered ever Day in hot Weather, for they are very thirſty Plants. Wi this Management, the Plants will in a Month after tranſplan ing riſe to a conſiderable Height; therefore they ſhould ſhifted into larger Pots, and placed in the Stove, plungi them into the Bark-bed, where they may have Room to gro

eſpecial

eſpecially the firſt and third Sorts, which uſually grow eight or nine Feet high, where they are well managed. But the ſecond and fourth Sorts ſeldom riſe above three Feet high, and do not ſpread their Branches very far, ſo theſe may be allowed leſs Room.

In the Middle of *July* theſe Plants will begin to flower, and the Seeds will be ripe ſoon after; therefore they muſt be gathered as ſoon as they change of a dark brown Colour, otherwiſe they will ſoon fall off, eſpecially thoſe of the two large Kinds, which will drop on the leaſt Touch when they are ripe. Theſe Plants will continue flowering till *Michaelmas* or later, if the Seaſon proves favourable; but when the Cold of the Autumn comes on, they will ſoon decay.

MIMOSA, The Senſitive Plant.

The *Characters* are;

The Flower conſiſts of one Leaf, which is ſhaped like a Funnel, having many Stamina *in the Center: theſe Flowers are collected into a round Head; from the Bottom of the Flower riſes the* Piſtillum, *which afterwards becomes an oblong, flat, jointed Pod, which opens both Ways, and contains in each Partition one roundiſh Seed.*

The *Species* are;

1. MIMOSA *ſeu frutex ſenſibilis. Tourn.* The common Senſitive Plant.
2. MIMOSA *humilis, fruteſcens, & ſpinoſa, ſiliquis conglobatis. Plum.* Dwarf ſhrubby Humble Plant, having Thorns, and the Pods growing together in Bunches.
3. MIMOSA *ſpinis horridiuſcula, & ſenſitiva magis. H. R. Par.* Greater Senſitive or Humble Plant, with very ſharp Thorns.
4. MIMOSA *latifolia, ſiliculis in orbem glomeratis. Tourn.* Broad-leaved or common Humble Plant.
5. MIMOSA *ſpuria de Pernambucq, dicta Mimoſa Italica. Zan.* The ſlothful Senſitive Plant: *vulgo.*
6. MIMOSA *herbacea procumbens & ſpinoſa, caule quadrangula, ſiliquis quadrivalvibus. Houſt.* Trailing herbaceous prickly Senſitive Plant, with ſquare Stalks, and Pods having four Cells.
7. MIMOSA *fruticoſa ſpinoſa, ſiliquis latis hirſutis & articulatis. Houſt.* Prickly ſhrubby Senſitive Plant, with broad hairy jointed Pods.
8. MIMOSA *non ſpinoſa, paluſtris & herbacea, procumbens, flore luteo pleno. Houſt.* Smooth marſh herbaceous trailing Senſitive Plant, with full yellow Flowers.
9. MIMOSA *fruteſcens ſpinoſa & hirſuta, tenuibus acaciæ foliis, ſiliquis articulatis. Houſt.* Shrubby prickly and hairy Senſitive Plant, with narrow Leaves like the Acacia, and jointed Pods.
10. MIMOSA *humilis fruteſcens & ſpinoſa, foliis acaciæ latioribus, ſiliquis conglobatis.* Dwarf ſhrubby and prickly Senſitive Plant, with broad Acacia Leaves, and Pods growing in Cluſters.
11. MIMOSA *herbacea non ſpinoſa minima repens. Sloan. Cat. Jam.* The leaſt creeping herbaceous Senſitive Plant, without Spines, commonly called Senſitive Graſs.

The firſt Sort is commonly known by the Name of *Senſitive Plant*, to diſtinguiſh it from the others, which are generally call'd *Humble Plants*, becauſe upon being touch'd, the Pedicle of their Leaves falls downward; whereas the Leaves of the other Sort are only contracted upon the Touch.

Theſe Plants are all propagated from Seeds, which muſt be ſown upon a Hot-bed early in the Spring; and when the Plants come up, they muſt be tranſplanted into ſmall Pots fill'd with light rich Earth, and plunged into a freſh Hot-bed, obſerving to water and ſhade them until they have taken Root: after which you muſt often refreſh them with Water, and let them have Air in proportion to the Warmth of the Seaſon, always obſerving to keep the Bed in a good Temper for Heat, as alſo to cover the Glaſſes every Night with Mats, which will greatly facilitate their Growth.

With this Management, in about a Month's Time, the Plants will have greatly advanced, and their Roots will fill the Pots; therefore you muſt remove them into larger Pots, by ſhaking them out of thoſe they are in, together with the Earth, which ſhould be preſerved to their Roots; and (after having pared off the Roots which were matted round the Outſide of the Ball of Earth) you muſt place the Plants into the larger Pots, filling them up with the like rich Earth; then plunge them into the Hot-bed, obſerving to water them well until they have taken Root; and if you ſee the Plants inclinable to droop, when the Sun ſhines warm upon the Glaſſes, you muſt ſhade them until they have recover'd, and are able to endure the Heat.

You muſt alſo obſerve to give them a greater Share of Air, as the Seaſon advances in Warmth; but you muſt never expoſe them to the open Air, which will not only retard their Growth, but alſo deſtroy the ſenſitive Quality; ſo that I have ſeen ſome Plants of theſe Kinds, which, after having been expoſed to the open Air a few Days, have intirely loſt their Motion.

The firſt of theſe Sorts, if duly water'd and preſerved in a kindly Warmth, will grow, in the Compaſs of one Seaſon, to the Height of eight or nine Feet, and produce great Quantities of Flowers; but unleſs the Autumn proves very favourable, the Seeds do ſeldom ripen, and the Plant being much tenderer than the other Sorts, is rarely preſerved thro' the Winter, tho' placed in the warmeſt Stoves; ſo that we are obliged to procure the Seeds from Abroad.

The ſecond Sort is of much humbler Growth, ſeldom riſing above two Feet high, but branches out very much, and is beſet with Thorns: This will abide two or three Years, if preſerved in a good Stove, and generally produces Seeds every Year; ſo that it is now become very common in the *Engliſh* Gardens, being the eaſieſt to preſerve, and the moſt plentiful in ſeeding of all the Sorts.

The third Sort hath very broad Leaves, and is greatly beſet with ſharp Thorns: This will riſe to the Height of five or ſix Feet, but has generally very ſlender Branches, and is tenderer than the laſt-mention'd: It rarely produces Seeds in this Country, but may be preſerved thro' the Winter in a very good Stove.

The fourth Sort has the quickeſt Motion of all the Kinds at preſent in *England:* This is ſomewhat like the third in Appearance, but grows more erect, and hath fewer Spines, and the Flowers are of a different Colour. The Seeds of this Kind are frequently brought over from *Barbadoes*, where, by the Plenty of Seeds brought over, it ſeems to be the moſt common in that Country.

The fifth Sort is preſerved in Botanick Gardens for Variety, but is a Plant of no great Curioſity: It hath ſomewhat the Appearance of the firſt Sort, and will grow erect to the Height of five or ſix Feet, and produce great Quantities of Seeds; but it having no Motion upon being touch'd, renders it leſs valuable than the others.

The ſixth, ſeventh and eighth Sorts were diſcovered by the late Dr. *William Houſtoun* at *La Vera Cruz*, from whence he ſent their Seeds into *England*, from which many Plants were raiſed. The ſixth Sort riſes to the Height of three Feet, and hath ſlender ſquare Stalks, which are ſtrongly armed with Spines. This is a perennial Plant, which creeps at the Root; ſo that it may be propagated by the Suckers, which are produced pretty plentifully. This hath not as yet produced any Flowers in *England*, for the Shoots generally die to the Root in Winter, and riſe again the following Spring. The Leaves of this Sort do not only cloſe on being touched, but alſo fall downward, ſo that it is ranked amongſt thoſe Kinds which are commonly called humble Plants.

The ſeventh Sort riſes to the Height of ſix or ſeven Feet, and hath a woody Stem, which is ſtrongly armed with crooked Spines. The Leaves conſiſt of ſeveral Wings, which have very narrow *Pinnæ*; theſe Leaves are alſo beſet on their under Side with ſharp crooked Spines all along the Midrib, ſo that it is troubleſome to go amongſt the Plants in the natural Place of their Growth. The Flowers of this Kind are of a bright purple Colour, which are ſucceeded by flat hairy jointed Pods, in which are included the Seeds. This Sort grows very plentifully in moiſt rich Places about *La Vera Cruz*, in the *Spaniſh Weſt-Indies.*

This Plant hath produced Flowers in *England*, but hath not perfected Seed, tho' it hath lived over the Winter, and has grown to a large Size. The Leaves of this Sort cloſe very ſoon on the Touch, but they fall downward very ſlowly, ſo that it is not ranged amongſt the humble Plants.

The eighth Sort grows plentifully in ſtanding Waters near *La Vera Cruz*, where the Branches float on the Water, in like Manner as do the Pond-weeds in this Country: But where the Water dries up, and leaves the Plants while they are young, they will grow more erect; and thoſe of them which have grown in *England*, have riſen to the Height of four or five Feet; but they ſpread themſelves on every Side, and required ſome Support, when they were full-grown. This Sort hath produced Flowers in *England*, but hath not perfected Seed; and being an annual Plant, is at preſent loſt in *Europe*. This is one of thoſe commonly called Senſitive Plants, for the Leaves do not fall on being touched. The ninth and tenth Sorts were diſcovered by Mr. *Robert Millar*, Surgeon, at *Carthagena*, from whence he ſent their Seeds into *England*, which have ſucceeded in ſeveral Gardens of the Curious. Theſe are both of them of the humble Kind, their Leaves falling on the ſlighteſt Touch. They will both of them live thro' the Winter, if they are placed in a very warm Stove.

The eleventh Sort is very common in *Jamaica*, where it creeps to the Ground, and grows in ſhort thick Tufts: This is very quick in its Motion; for, on drawing a Stick over the Plants, they will immediately contract, and leave the Impreſſion for ſome Time, till the Plants recover.

Theſe Plants were moſt of them thought to be Annuals formerly, becauſe upon the firſt Approach of cold Weather they were deſtroy'd; but ſince the modern Invention of Bark-ſtoves, moſt of theſe Sorts have been preſerved two or three Years, and do produce Seeds very well.

The Stove in which theſe Plants are placed in Winter, ſhould be kept to *Anana*'s Heat, (as mark'd on Mr. *Fowler's Thermometers*); and during that Seaſon they ſhould be frequently refreſh'd with Water, which muſt be placed in the Stove at leaſt twenty-four Hours before it be uſed, that it may have nearly an equal Warmth to the Air of the Stove; but you muſt not give it to them in large Quantities, which will rot their Roots, and cauſe them to decay: You muſt alſo obſerve to pick off all decay'd Leaves which may appear at that Seaſon; which, if not taken off, will harbour Inſects, to the great Prejudice of the Plants.

But where there is not the Conveniency of a good Stove to preſerve theſe Plants thro' the Winter, their Seeds may be annually procured, and a few Plants raiſed, which may be kept in a Hot-bed under Glaſſes, where they will continue until the Cold approaches in Autumn, and, being a great Curioſity, are worthy of Care in every good Garden.

The Philoſophical Reaſon of the ſudden Motion of this Plant, upon its being touch'd, has not, that I know of, been explain'd by any Perſon; but I ſhall here inſert what has been advanced on that Head.

The Phænomenon thereof is worthy Admiration, that not only in the Evening, or towards Night, but at all Hours of the Day, with the leaſt Touch of a Stick, or gentle one with the Hand, the Leaves, juſt like a Tree a dying, droop, and complicate themſelves with all the Quickneſs imaginable, and preſently after erect and recover themſelves, returning to their former Poſition; ſo that a Perſon would be induced to think they were really endow'd with the Senſe of Feeling.

This ſeem'd ſo hard to be diſcover'd, that a curious *Malabarian* Philoſopher, upon his obſerving the Nature of this Plant, ran mad; juſt as *Ariſtotle* is ſaid to have flung himſelf headlong into the Sea, becauſe he could not comprehend the Ebbing and Flowing thereof.

The Reaſon of theſe Plants thus drooping and reviving again ſo ſoon, may be accounted for as follows:

It is occaſion'd by the Structure of their Muſcles or Fibres, their Nerves, their Valves, and their Pores.

Firſt, By reaſon that the interior Nerves which belong to their ſuperior Muſcles or Fibres of the Leaves being wider than thoſe exterior which belong to the inferior; and therefore the Vapour aſcending out of the Earth thro' the inferior Nerves, as they are pretty broad, having a large Influence on the upper Fibres of the Leaf, and by reaſon of the Situation of the Valves croſs-wiſe, not being able to return to the Earth, dilate themſelves with reſpect to their Latitude, and abbreviate them in Longitude, and ſo erect the Leaves on which theſe Fibres are inſerted, to ſuch a Height, as their Articulation or Flexibility will permit.

Hence it is, that by the Inflation of the ſuperior Muſcles, and the Erection of the Leaves, the Breath which is in the inferior Muſcles or Fibres of the Leaves, ſo preſſed and ſo forced to open the Valves and Pores out of the narrower Nerves loooking into the broader or wider, and then to croſs over with the other Spirits in the wider Nerves into the ſuperior Muſcles of the Leaves, and raiſe them upwards; and that ſo much the more, becauſe the inferior Valves, by their Situation croſs-wiſe, hinder the Deſcent of the Fumes again into the Ground.

The Spirits then aſcending out of the Earth in pretty large Quantities, and pretty ſtrong, thro' the interior and wider Nerves, do not ſuffer the Valves, out of the wider Nerves, entering into the narrower, to be open'd, or the Fumes to croſs thro' theſe out of the wider Nerves into the narrower. When therefore the ſuperior Part of the Leaves are touch'd with the Hand, then the Spirits in thoſe upper Parts of the Leaves being driven more vehemently by that Touch, tend downwards, thro' the interior and wider Nerves, and by that means open the Valves and Pores, which look from the wider and inward Nerves into the outward and narrower, and, by reaſon of the Stoppage of the Valves croſs-wiſe, being not able to deſcend, they aſcend thro' them, and, by their Aſcent, ſhut up the Valves looking from the narrower Nerves into the broader, and ſo neceſſarily deſcend into the inferior Muſcles or Fibres of the Leaves, and by inflating them, and abbreviating them as to their Length, bend thoſe lower Leaves as much as their Articulation or Flexibility will allow of.

Then, after thoſe Leaves have been ſo preſs'd downwards, and the Hand removed from the Plant, the Exhalations out of the Earth aſcend into the Stalk in greater Quantities thro' the inward and wider Nerves, and thro' the Valves that go croſs them thro' the exterior and narrower, and by that means firſt ſhut thoſe Valves which come from the wider and inward Nerves into the exterior, and then proceeding forward, (*i. e.* the Exhalations) croſs over to the ſuperior Muſcles of the Leaves; and by inflating thoſe, they ſomewhat raiſe the Leaves which were depreſs'd; and by that ſmall Sublatation of the Leaves, preſs the Exhalations, which the inferior Muſcles of the Leaves are full of; and thoſe being preſs'd, they open the Valves in the narrower Nerves, out of the exterior Nerves into the interior, and ſo croſs over to the wider and inner Nerves; and there, by reaſon of the Vehemency of Fumes in great Quantities exhaling out of the Earth into them, and cloſing thoſe Valves, which go into the narrower Nerves, they can neither deſcend nor croſs over to the Sides, but are neceſſarily terminated in the ſuperior Muſcles of the Leaves, by Exhalations perpetually aſcending out of the Earth, thro' the wider Nerves; which Leaves, as their upper Parts are full of copious Exhalations, ſo they are thereby dilated.

MINT. *Vide* Mentha.

MIRABILIS PERUVIANA. *Vide* Jalapa.

MISLETOE. *Vide* Viſcum in the Appendix.

MITELLA, [ſo call'd of *Mitella*, Lat. a *little Mitre*, becauſe the Seed-veſſel of this Plant reſembles a Biſhop's Mitre] Baſtard *American* Sanicle.

The *Characters* are;

It hath a perennial Root: The Cup of the Flower conſiſts of one Leaf, and is divided into five Parts: The Flower conſiſts of five Leaves, which expand in form of a Roſe: *The Ovary becomes a roundiſh Fruit, which terminates in a Point, gaping at the Top, in form of a Biſhop's Mitre, and full of roundiſh Seeds.*

The *Species* are;

1. MITELLA *Americana, florum petalis integris.* Tourn. *American* Mitella, whoſe Flower-leaves are intire.
2. MITELLA *Americana, florum petalis fimbriatis.* Tourn. *American* Mitella, with fringed Flower-leaves.
3. MITELLA *Americana, flore ſquallide purpureo, villoſo. Boerh. Ind. American* Mitella, with hairy Flowers of a dirty purple Colour.
4. MITELLA *Americana maxima tinctoria. Inſt.* R. H. The Arnotto or Anotto.

The firſt three Sorts are preſerved in curious Botanick Gardens for Variety; but there being very little Beauty in their Flowers, they are ſeldom propagated in Gardens for Pleaſure. They are very hardy, and will thrive in almoſt any Soil or Situation, and may be propagated either from Seeds, or by parting their Roots, which may be done either in Spring or Autumn, in the Manner as is practiſed for *Polyanthus's*, &c. and being planted in a ſhady Situation, will grow very vigorouſly; ſo that, for the ſake of Variety, a few Roots may be admitted in ſhady Borders where few better Plants will thrive.

The fourth Sort riſes to the Height of ten or twelve Feet, and hath a woody Stem, which is beſet with many Branches at the Top, which are furniſhed with broad Leaves, ſhaped ſomewhat like a Heart; from theſe Branches the Flowers come out in ſmall Cluſters, which conſiſt of ſeveral Leaves, and expand in form of a Roſe; theſe are of a pale Fleſh-colour. The Flowers are ſucceeded by brown Pods, ſhaped like a *Mitre*, and are echinated on the Outſide in the ſam Manner as the Cheſnut; in which Pods are contained many irregular Seeds, which are of a red Colour.

The Seeds of this Plant are uſed to make a Dye, by the Inhabitants of *America*. The Manner of preparing it is as follows: They ſteep the Seeds in Water, until the outwar red Part is diſſolved intirely from them; then they boil th Water which is impregnated, ſeveral Times, (after the ſam manner as they do the Juice of the *Sugar Cane*) until it becomes of a pretty thick Conſiſtence; then they put it int Canvaſs, which is ſpread over a Fire of hot Aſhes, which dot not flame, to bring it to a farther Conſiſtence, when they mak it up into Balls, which are ſent into *Europe*, where it is uſ in Dying.

The *Indians* make uſe of this Colour to paint their Bodies eſpecially when they go to War, in order, as ſome ſuppoſe, t prevent their diſcovering the Blood when they are wounded

bein

being almoſt of the ſame Colour, ſo is ſuppoſed to make them courageous. But the chief Uſe of it is to prevent the *Muſketa's* and Flies from annoying them. This Dye is alſo mix'd with Chocolate to give it a Colour.

It grows in the warmeſt Parts of *America*, from whence the Seeds are pretty frequently ſent into *England*. Theſe Seeds ſhould be ſown early in the Spring of the Year, in ſmall Pots filled with light rich Earth, which ſhould be plunged into a moderate Hot-bed of Tanner's-bark, and the Earth ſhould be frequently watered, to forward the Vegetation of the Seed. When the Plants are come up two Inches high, they ſhould be carefully tranſplanted, each into a ſeparate ſmall Pot; filled with light rich Earth, and then plunged again into the Tanners-bark, obſerving to ſhade them from the Sun, until they have taken new Root; after which Time they muſt be frequently refreſhed with Water, and in hot Weather the Glaſſes of the Hot-bed ſhould be raiſed every Day, to admit freſh Air to the Plants. With this Management the Plants will grow to be a Foot high by the Middle of *July*, and will have filled the Pots with their Roots; therefore they ſhould then be ſhaken out of the Pots, and their Roots carefully trimmed, and then put into Pots a little larger, and plunged again into the Hot-bed, and managed as before. Theſe Plants may remain in the Hot-bed until toward *Michaelmas*, when the Nights begin to be cold, at which Time they muſt be removed into the Stove, and plunged into the Bark-bed, where they may enjoy a good Share of Warmth in the Winter-ſeaſon, otherwiſe they cannot be preſerved in this Country: they muſt be frequently refreſhed with Water during the Winter-ſeaſon, but they ſhould not have too much given to them each Time, eſpecially if they ſhould caſt their Leaves, which they frequently do toward the Spring. As theſe Plants are very tender, ſo they ſhould conſtantly remain in the Stove, obſerving in the Summer-ſeaſon, when the Weather is warm, to admit a large Share of freſh Air to the Plants, as alſo to water them frequently, but in cold Weather they muſt be kept very warm. When theſe Rules are duly obſerved, the Plants will thrive very faſt, and grow to the ſame Height which they uſually do in their native Soil.

MOLDAVICA, [this Plant is ſo call'd of *Moldavia*, becauſe it was brought to us from that Country, where it grows without Culture] Turkey Balm.

The *Characters* are;

It is a Plant with a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is arched, cut into two Parts, and reflex'd: The under Lip is alſo divided into two Parts, both ending in border'd Jaws: The Flower-cup is hollow, and generally cut into two unequal Lips, out of which ariſes the Pointal, attended with four Embryo's, which afterwards become ſo many oblong Seeds.

The *Species* are;

1. Moldavica *betonicæ folio, flore cæruleo. Tourn.* Turkey Balm, with a Betony Leaf, and a blue Flower.
2. Moldavica *betonicæ folio, flore albo. Tourn.* Turkey Balm, with a Betony Leaf, and a white Flower.
3. Moldavica *betonicæ folio, flore purpuro-cæruleo. Tourn.* Turkey Balm, with a Betony Leaf, and a purpliſh blue Flower.
4. Moldaviga *orientalis, betonicæ folio, flore magno violaceo. T. Cor.* Eaſtern Moldavica, with a Betony Leaf, and a large Violet-colour'd Flower.
5. Moldavica *orientalis, betonicæ folio, flore parvo cæruleo. T. Cor.* Eaſtern Moldavica, with a Betony Leaf, and a large whitiſh Flower.
6. Moldavica *orientalis, ſalicis folio, flore parvo cæruleo. T. Cor.* Eaſtern Moldavica, with a Willow Leaf, and a ſmall blue Flower.
7. Moldavica *orientalis, ſalicis folio, flore parvo albo. T. Cor.* Eaſtern Moldavica, with a Willow Leaf, and a ſmall white Flower.
8. Moldavica *Americana, trifolia, odore gravi. Tourn.* Three-leav'd *American* Moldavica, with a ſtrong Scent, *commonly call'd*, The Balm of Gilead.

The ſeven firſt Species are annual Plants, which periſh ſoon after they have perfected their Seeds: theſe may be propagated by ſowing their Seeds in *March*, upon a Bed of freſh light Earth, in a warm Situation; and when the Plants are come up about two Inches high, they ſhould be tranſplanted into the Borders of the Pleaſure-Garden, obſerving to water them until they have taken Root: after which they will require no farther Care, but to keep them clear from Weeds; and if they grow pretty tall, to ſupport them with Sticks, to prevent their being broken by Winds.

In *June* and *July* they will produce their Flowers; and in *Auguſt* their Seeds will be perfected, when they muſt be gather'd, and preſerved dry for the ſucceeding Spring.

The Seeds may alſo be ſown upon a warm Border in *Auguſt*, where the Plants will come up ſoon after, and will endure the Cold of our ordinary Winters very well, provided they have a dry Soil, and a warm Situation.

In the Spring they may be tranſplanted out into the Borders where they are deſigned to be continued, where they will flower early, and produce good Seeds; whereas it ſometimes happens, that if the Seaſon proves cold and wet, thoſe Plants which are ſown in the Spring do not perfect their Seeds.

There is no very great Beauty in theſe Plants; but as they require little Culture, ſo they may be admitted into large Borders of the Flower-Garden, where being intermix'd with other Plants, they afford an agreeable Variety. The moſt valuable Sorts are the two Oriental Kinds with large Flowers; theſe commonly grow about eighteen Inches high, and divide into ſeveral Branches, but do not take up much Room; and being annual Plants, there will be no Danger of their injuring others that may grow near them. *

The eighth Sort is an abiding Plant, which may be eaſily propagated by planting Cuttings, during any of the Summer Months, in a Border of rich Earth, obſerving to water and ſhade them until they have taken Root, which they do commonly in about three Weeks Time; after which they will require no farther Care than only to keep them clear from Weeds, till they have made a conſiderable Progreſs, when they ſhould be taken up, preſerving a Ball of Earth to each Plant, and ſet into Pots fill'd with freſh light Earth, placing them in a ſhady Situation until they have taken freſh Root; after which, they may be expoſed to the open Air until the Middle or latter End of *October*, when they muſt be removed into Shelter, otherwiſe they will be liable to ſuffer by hard Froſts; tho' they ſhould be placed where they may enjoy as much free Air as poſſible in mild Weather, and only require to be protected from ſevere Cold; for in moderate Winters I have had them endure abroad very well, when planted under a warm Wall.

They will require frequently to be water'd, when planted in Pots; but in the Winter you ſhould not let them have it in great Quantities, which will be apt to rot their Roots, and deſtroy them. This laſt Species is preſerved in ſeveral Gardens, for its Oddneſs; and the ſtrong Balſamick Scent which the Leaves emit, upon being bruiſed, which gave occaſion to many Perſons formerly to ſuppoſe the *Balm of Gilead* was taken from this Plant.

MOLLE, The *Indian* Molle *or* Maſtick-Tree.

The *Characters* are;

It hath pinnated Leaves, like thoſe of the Lentiſcus, *but are terminated by an odd Lobe; the Flower expands in the form of a Roſe; and the Fruit reſembles a Grain of Pepper.*

We have but one *Species* of this Tree in *England*; which is,

Molle, *Cluſ. in Monard.* The Arbor Molle *or Indian* Maſtick-Tree.

This Tree is preſerved in many curious Gardens in *England*, but rarely produces any Flowers in this Country.

It may be propagated by laying down the tender Branches, which in two Years will take Root, when they may be taken off from the old Plants, and planted into Pots fill'd with freſh light Earth, obſerving to water and ſhade them until they have taken Root.

But as it is very difficult to make this Tree grow from Layers, ſo it will be neceſſary to ſlit the Branches when laid, which will facilitate their Rooting; and when you cut them off from the old Plants, (which ſhould be done in *April*) if you place the Pots upon a moderate Hot-bed, it will cauſe them to take Root much ſooner, provided you water and ſhade them carefully; but you muſt obſerve to let them have Air in Proportion to the Warmth of the Seaſon; and when they have taken freſh Root, you muſt inure them to the open Air by degrees, into which they ſhould be removed toward the latter End of *May*, placing them in a Situation where they may be defended from violent Winds, in which they may remain until the *October* following, when they muſt be removed into the Green-houſe, placing them where they may have a great Share of free Air in mild Weather; for they only require to be protected from ſevere Cold.

This Tree will grow to the Height of ſeven or eight Feet, but commonly produces its Shoots very irregular, ſo that it is very difficult to form it to a regular Head; for which Reaſon it is not ſo much eſteem'd, (except by the Curious in *Botany*) as the *Lentiſcus*; but for Variety it may have a Place in all curious Green-houſes.

MOLUCCA, [this Plant takes its Name of the *Molucca* Iſlands, becauſe it was found there] *Molucca* Balm.

The *Characters* are;

It is a verticillate Plant with a labiated Flower, conſiſting of one Leaf, whoſe upper Lip is hollow, like a Spoon, but the under Lip is cut into three Segments; out of the Flower-cup ariſes the Pointal, attended, as it were, by four Embryo's, which afterwards turn to ſo many angular Seeds, which are incloſed in the Bell-ſhaped Calyx.

The *Species* are;

1. MOLUCCA *lævis*. *Dod.* Smooth *Molucca* Balm.
2. MOLUCCA *ſpinoſa*. *Dod.* Prickly *Molucca* Balm.

Theſe Plants are annual, ſeldom abiding after they have perfected their Seeds. They are preſerved only in ſuch Gardens where a great Variety of Plants are maintain'd, being Plants of no great Beauty or Uſe. Theſe may be propagated by ſowing their Seeds in *March*, upon a Bed of freſh light Earth, in an open Situation, where the Plants will come up ſoon after; and when they are about two Inches high, they muſt be tranſplanted out, either into freſh Beds of light Earth, or in the Borders of the Pleaſure-Garden, placing them at two Feet Diſtance; for their Branches will extend pretty far, if the Soil be rich; and when they have taken Root, they will require no farther Care, but only to keep them clear from Weeds, and faſten them to Sticks, to prevent their being broke by Winds when they advance.

In *July* theſe Plants will flower, and if the Seaſon proves warm, their Seeds will be perfected in *September*, but if the Seaſon be cold and moiſt, they commonly periſh without producing good Seeds in this Country; for which Reaſon theſe Plants ſhould be raiſed in Autumn, and preſerved thro' the Winter under a common Frame, and in the Spring tranſplanted out, as before, when they will flower early, and produce good Seeds.

MOLY, [this Plant is ſo named of μωλύω, to *grieve* or *be in Pain*, becauſe *Homer* repreſents it as good to expel Poiſon] Wild Garlick.

The *Characters* are;

It agrees in every reſpect with the Garlick, *but hath, for the moſt part, a ſweet Scent; and the Flowers are produced in an Umbel.*

The *Species* are;

1. MOLY *latifolium, liliflorum*. *C. B. P.* Broad-leav'd Moly of *Theophraſtus*.
2. MOLY *latifolium Indicum*. *C. B. P.* Broad-leav'd *Indian* Moly.
3. MOLY *latifolium Hiſpanicum*. *C. B. P.* Broad-leav'd *Spaniſh* Moly, with purple Flowers.
4. MOLY *latifolium, flavo flore*. *H. Eyſt.* Broad-leav'd yellow Moly.
5. MOLY *anguſtifolium, umbellatum*. *C. B. P.* Narrow-leav'd Moly, *commonly call'd*, *Homer*'s or *Dioſcorides*'s Moly.
6. MOLY *anguſtifolium, foliis reflexis*. *C. B. P.* Narrow-leav'd Moly, with reflex'd Leaves, *commonly call'd*, The Serpent Moly.
7. MOLY *moſchatum, capillaceo folio*. *C. B. P.* The ſweet Moly of *Montpelier*, *vulgo*.

There are ſome other Varieties of this Plant, which are preſerv'd in curious botanick Gardens abroad, but thoſe here mention'd are what I have obſerved in the *Engliſh* Gardens.

They are all very hardy Plants, and may be eaſily multiplied by their Off-ſets, which they ſend forth in great Plenty: The beſt Seaſon to tranſplant them is in *Auguſt* or *September*, juſt after their Leaves decay; for if they are permitted to remain long after, and the Seaſon ſhould prove moiſt, they will ſend forth freſh Fibres, when it will be too late to remove 'em, unleſs they are taken up with Balls of Earth.

They will grow in almoſt any Soil or Situation, but will thrive beſt in a light, ſandy Soil, and an open Expoſure.

They commonly produce their Flowers in *May* and *June*, except the *ſweet-ſcented Montpelier* Kind, which ſeldom flowers till *Auguſt*, and are pretty Varieties in the large Borders of the Pleaſure-Garden, where, being intermix'd with other bulbous-rooted Flowers, they afford an agreeable Variety; but they ſhould not be permitted to remain longer than two Years before they are tranſplanted, becauſe they produce a great Number of Off-ſets, (eſpecially *Homer*'s *Moly*) which, if not taken from the old Roots, will ſtarve 'em and cauſe their Flowers to be very weak.

MOMORDICA, [The Origin of the Name is unknown] Male Balſam-Apple.

The *Characters* are;

The Flower conſiſts of one Leaf, is of the expanded, bell-ſhap'd Kind, but ſo deeply cut, as to appear compos'd of five diſtinct Leaves; theſe Flowers are ſome Male (or barren), others Female, growing upon the Top of the Embryo, which is afterwards chang'd into a Fruit, which is fleſhy, and ſometimes more or leſs tapering, and hollow; and when ripe, uſually burſts, and caſts forth the Seeds with an Elaſticity; which Seeds are wrapped up in a membranous Covering, and are, for the moſt part, indented on their Edges.

The *Species* are;

1. MOMORDICA *vulgaris*. *Tourn.* The common Male Balſam-Apple.
2. MOMORDICA *Zeylanica, pampinea fronde, fructu breviori*. *Tourn.* Male Balſam-Apple of Ceylon, with Vine-leaves and a ſhort Fruit.
3. MOMORDICA *Zeylanica, pampinea fronde, fructu longiori*. *Tourn.* Male Balſam-Apple of Ceylon, with Vine-leaves and a longer Fruit.
4. MOMORDICA *Americana, fructu reticulato ſicco*. *Com. Rar.* Male Balſam-Apple, of America, with a dry netted Fruit.

Theſe Plants are all annual, their Seeds muſt be ſown on a Hot-bed the Beginning of *March*, and when the Plants come up, they ſhould be tranſplanted out into a freſh Hot-bed, after the Manner of *Cucumbers* or *Melons*, putting two Plants of the ſame Kind, under each Light, and the Plants water'd and ſhaded until they have taken Root; after which they muſt be treated as *Cucumbers*, permitting their Branches to extend upon the Ground in the ſame Manner, and obſerve to keep them clear from Weeds.

With this Management (provided you do not let them have too much Wet, or expoſe 'em too much to the open Air) they will produce their Fruit in *July*, and their Seeds will ripen in *Auguſt*, when you muſt obſerve to gather it as ſoon as you ſee the Fruit open, otherwiſe it will be caſt abroad, and with Difficulty gather'd up again.

Theſe Plants are preſerv'd in curious Gardens for the Oddneſs of their Fruit; but as they take up a great deal of Room in the Hot-beds, requiring frequent Attendance, and being of little Beauty or Uſe, ſo they are not much cultivated in *England*, except in *Botanick* Gardens for Variety.

MONBIN, The Hog Plum-tree.

The *Characters* are;

It hath a roſe-ſhaped-Flower, conſiſting of ſeveral Leaves, which are ranged in a circular Order; from whoſe Cup ariſes the Pointal, which afterward becomes an oval fleſhy ſoft Fruit incloſing a hard Stone, in which are contained four Kernels or Seeds.

We have but one Sort of this Tree; *(viz.)*

MONBIN, *arbor, foliis fraxini, fructu luteo racemoſo*. *Plum. Nov. Gen.* The Hog Plum-tree; vulgo.

This Tree is a Native of the warmeſt Parts of *America*, where it grows in the *Savanna*'s and low marſhy Places in great Plenty. It riſes to be forty or fifty Feet high, and divides into a great many crooked Branches, which are beſet with winged Leaves ſomewhat like thoſe of the *Aſh-tree*. The Flowers, which appear in the Spring, are produced in large pyramidal Bunches at the Extremity of the Branches, which are of a white Colour, and are very ſweet. Theſe are ſucceeded by ſeveral yellow oval-ſhaped Plums, growing in Cluſters. The Wood of this Tree being ſoft, is uſed inſtead of Cork, to ſtop Bottles in *America*.

This is a very tender Tree, ſo muſt be conſtantly kept in the Stove, otherwiſe it cannot be preſerved in this Country. It may be propagated by Cuttings (which is the moſt common Method practiſed in *America*); but if theſe are to be brought to *England*, they ſhould be planted pretty cloſe together in Tubs of Earth, and placed in a ſhady Situation, until they have taken good Root, before they are put on Board the Ship; and in their Paſſage they muſt be kept from Salt-water, nor ſhould they be too plentifully ſupplied with freſh; for too much Moiſture hath deſtroyed many of theſe Plants, before they have arrived in *England* ; for if the tender Fibres are rotted, the Bark of the older Shoots will ſoon decay. When they arrive in pretty good Health, they ſhould be carefully taken out of the Tubs, and each planted into a ſeparate Pot, filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving frequently to refreſh them with Water ; but it muſt not be given to them in large Quantities, until they have taken good Root. If they come over in a hot Seaſon, it will be proper to ſhade them from the Sun, until they are rooted ; and at that Seaſon they will require but a very moderate Warmth in the Hot-bed ; for too great Warmth would then be injurious to them. But when they arrive late in the Year, the Bed ſhould have a large Share of Heat, in order to forward their Rooting, before the Winter's Cold comes on ; for if they are not pretty well rooted before Winter, there will be ſmall Hopes of their living till Spring, ſo that they ſhould never be ſent over too late in the Year.

Theſe Plants may alſo be propagated by ſowing of their Stones, which ſhould be brought over as freſh as poſſible. Theſe ſhould be ſown in the Spring of the Year, in ſmall Pots filled with light rich Earth, and then plunged into a Hot-bed of Tanners-bark, where, if the Bed is in a good Temperature for Heat, and the Pots of Earth are duly moiſtened, the Plants will come up in about a Month after Sowing, when they ſhould have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon, and they muſt be frequently refreſhed with Water. In about three Weeks or a Month after the Plants appear above Ground, they will be fit to tranſplant, when each Plant ſhould be planted in a ſeparate ſmall Pot, filled with light rich Earth, and then plunged into the Hot-bed again, where they muſt be ſhaded from the Sun, until they have taken new Root ; after which Time they muſt be duly watered, and have a pretty large Share of freſh Air in warm Weather.

When the Plants have grown ſo large as to have filled the Pots with their Roots, they ſhould be ſhifted into others of a larger Size, being careful not to ſhake the Earth from their Roots, but the Fibres round the Ball of Earth ſhould be trimm'd. They muſt then be plunged into the Hot-bed again, provided the Plants are not too tall to ſtand under the Glaſſes, without Injury to their Leaves ; in which Caſe they muſt be plunged into the Bark-bed in the Stove, where they may have Room to advance in Height. But if they have Room in the Hot-bed, they may remain there till about *Michaelmas*, when the Nights begin to be cold, at which Time they muſt be removed into the Stove, and plunged into the Bark-bed, in the warmeſt Part of the Stove. During the Winter Seaſon they muſt be often refreſhed with Water ; but it muſt not be given to them in large Quantities, when the Seaſon is cold ; eſpecially, if they ſhould caſt their Leaves, which they frequently do toward the Spring, then they muſt have but little Water, until they put out new Leaves ; becauſe too much Moiſture is injurious to them, when they are in almoſt an unactive State.

Theſe Plants are too tender to live in the open Air in *England*, even in the warmeſt Seaſon of the Year ; ſo that they ſhould conſtantly remain in the Bark-ſtove, where they ſhould have a large Share of freſh Air in Summer ; and they will at that Seaſon require to be plentifully watered, for they naturally grow in low moiſt Places ; but in Winter they muſt be kept very warm : with this Management, the Plants will thrive very faſt, and in few Years will produce their Fruit.

MONTIA.

The *Characters* are ;

It hath a funnel-ſhaped Flower, conſiſting of one Leaf, whoſe under Part is tubulous, but the upper Part is expanded, and cut into five Parts ; the Fruit which ſucceeds the Flower, is a bicapſular flat Seed-veſſel, which is ſurrounded on the Borders with a Plume, which expands like Rays.

We have but one Plant of this Genus ; *(viz.)*

MONTIA *arboreſcens, abutili folio ſerrato, fructu racemoſo. Houſt.* Tree-like Montia with a ſawed abutilon Leaf, and the Fruit growing in Bunches.

This Plant was diſcovered by the late Dr. *William Houſtoun*, near old *La Vera Cruz* in *New Spain*, who gave this Name to it in Honour to Dr. *Monti*, Profeſſor of *Botany* at *Bononia*.

It grows about ſixteen or eighteen Feet high, and hath a woody Stem, which divides into ſeveral Branches ; theſe are beſet with Leaves ſomewhat like thoſe of the yellow *Mallow*, which are five Inches long, and four broad, ending in a Point ; theſe are ſawed round the Edges, and have a Down on their under Sides. The Flowers are of a greeniſh yellow Colour, and are produced in Bunches. The Seaſon of its Flowering is in *January*, in the native Place of its Growth, and the Seeds are ripe in *March*.

This Plant is propagated by Seed, which ſhould be ſown early in the Spring on a Hot-bed ; and when the Plants are come up about two Inches high, they ſhould be each tranſplanted into a ſeparate ſmall Pot, filled with light freſh Earth, and plunged into a moderate Hot-bed, being careful to ſhade them from the Sun until they have taken Root ; after which Time they muſt have a large Share of freſh Air admitted to them in warm Weather, and they muſt be duly watered. In this Hot-bed the Plants may remain till Autumn, when they muſt be removed into the Stove ; and the firſt Year, while the Plants are young, it will be proper to plunge them in the Bark-bed ; but the following Winters they will do very well in the dry Stove, which ſhould be kept up to temperate Heat. And in the middle of the Summer, they will bear to be expoſed for near three Months, provided they are placed in a warm Situation. In hot Weather theſe Plants muſt be frequently watered, and as they advance in their Growth, ſo they ſhould be ſhifted into larger Pots, filled with light freſh Earth. With this Management the Plants will thrive very well, and in two or three Years will produce Flowers.

MORINA.

The *Characters* are ;

It hath a tubulous anomalous perſonated Flower, conſiſting of one Leaf, which is divided into two Lips : the upper Lip is again divided into two Parts, but the under Lip is divided into three. From the Flower-cup, which is for the moſt part bifid, ariſes the Pointal, fixed like a Nail in the hinder Part of the Flower ; but is barren, for the Flower-cup reſts on the Embryo, and is ſurrounded by another Cup as a Sheath, in which are many roundiſh and angular Seeds.

We have but one Sort of this Plant, *(viz.)*

MORINA *Orientalis, carlinæ folio. Tourn. Cor.* Eaſtern Morina, with a Leaf of the Carline Thiſtle.

This Plant was diſcovered by Dr. *Tournefort* in his Travels in the *Levant*, who gave it this Name in Honour to Dr. *Morin* a Phyſician at *Paris*.

This Plant is propagated by Seed, which ſhould be ſown ſoon after it is ripe in the Autumn, otherwiſe the Plants will not come up the following Summer ; for I have ſeveral times obſerved, where the Seeds have been ſown in the Spring, they have remain'd in the Ground fourteen or fifteen Months, before the Plants have appeared. Theſe Seeds ſhould be ſown in the Places where the Plants are to remain, becauſe they ſend forth tap Roots, which run very deep into the Ground ; and when theſe are broken or injured in tranſplanting, the Plants ſeldom thrive after. They may be ſown in open Beds or Borders of light freſh Earth, being careful to mark the Places, that the Ground may not be diſturbed, for it frequently happens, that the Seeds do not come up the firſt Year, when they are ſown in Autumn ; but when they are ſown in the Spring, they never come up the ſame Year. The Ground where the Seeds are ſown, muſt be kept clear from Weeds, which is all that is neceſſary to be done until the Plants come up, when, if the Seaſon ſhould prove dry, it will be proper to refreſh them two or three times a Week with Water ; and where they come up too cloſe together, they ſhould be thinned ſo as to leave them near eighteen Inches apart ; after which Time they will require no other Culture, but to keep them conſtantly clear from Weeds ; and in the Spring, juſt before the Plants put out new Leaves, to ſtir the Ground gently between them, and lay a little freſh Earth over the Surface of the Bed, to encourage the Plants.

In Autumn theſe Plants decay to the Ground, and ſend forth new Leaves the following Spring ; but it will be three Years from the Time of the Plants firſt coming up, to their Flowering ; but after that Time, they will flower every Seaſon, and the Roots will continue many Years, provided they are not diſturbed. Theſe Plants, when in Flower, make an agreeable Diverſity, when mixed with other hardy flowering perrennial Plants ; and as they do not require much Care to cultivate them, ſo they deſerve Room in every good Flower-Garden.

MORUS, [of μαυρὸς, *black*, becauſe its Fruit is ordinarily ſo] The Mulberry-tree.

The *Characters* are ;

It hath large, rough, roundiſh Leaves ; the Male Flowers (or Katkins, which have a Calyx conſiſting of four Leaves) are *ſometimes produced upon ſeparate Trees, at other times at remote Diſtances from the Fruit on the ſame Tree, the Fruit is compoſed of ſeveral Protuberances, to each of which adhere four ſmall Leaves; the Seeds are roundiſh, growing ſingly in each Protuberance.*

The *Species* are;

1. MORUS *fructu nigro.* *C. B. P.* The common Black Mulberry.
2. MORUS *fructu albo.* *C. B. P.* The White Mulberry.
3. MORUS *fructu nigro minori, foliis eleganter laciniatis.* *Tourn.* The leſſer Black Mulberry, with Leaves neatly jagged.
4. MORUS *fructu albo minori, ex albo purpuraſcente.* *Tourn.* The ſmall purpliſh White Mulberry.
5. MORUS *Virginiana, foliis latiſſimis ſcabris, fructu rubro longiori.* *Cat. Plant. Hort.* The broad-leav'd Virginian Mulberry, with long red Fruit.
6. MORUS *Virginienſis arbor, loti arboris inſtar ramoſa, foliis ampliſſimis.* *Pluk. Phyt.* The large-leav'd Virginian Mulberry, with blackiſh Shoots, ſomewhat like thoſe of the Lote *or* Nettle-tree.

The firſt of theſe Sorts is very common in moſt Gardens, being planted for the Delicacy of its Fruit: It may be propagated by ſowing the Seeds, or by laying down the tender Branches, which in two Years will take Root, and may then be tranſplanted into the Places where they are to remain. Thoſe Plants which are propagated from Seeds are commonly the moſt vigorous, and generally make the ſtraiteſt Stems, but then there is a very great Hazard of their being fruitful; for it often happens, that ſuch Plants are, for the moſt part, of the *Male* Kind, which produce *Katkins*, but ſeldom have much Fruit; for which Reaſon, thoſe who are deſirous to have fruitful Trees, ſhould always propagate them by Layers from ſuch Trees as do produce Plenty of good Fruit. But as the Trees thus rais'd are ſubject to have crooked, unſightly Stems, ſo there ſhould be Care taken in the Choice of ſtrait Shoots to make Layers; and when they are tranſplanted out, they ſhould have ſtrait Stakes fix'd down by each, to which they ſhould be faſten'd as the Shoot is extended, until it comes to the Height you deſign the Stem; then you may ſuffer the Branches to extend as they are inclinable, for this Tree ſhould not be often prun'd, but only ſuch Branches ſhould be cut off which ſhoot croſs, and bruiſe themſelves by rubbing againſt each other, and ſuch as decay ſhould alſo be cut off.

This Tree delights in a light Soil, not too wet nor over dry, and ſhould have an open Expoſure; for if it be planted too near to other Trees or Buildings, ſo as to be ſhaded thereby, the Fruit ſeldom ripens well; though if they are planted in a Situation where they may be defended from the violent *Weſt* and *South-Weſt* Winds, which very often blow down and deſtroy great Quantities of the Fruit, it will be of great Advantage; but they ſhould always be open to the *Eaſt* and *South-Eaſt* Sun, which is of great Service in drying up the Moiſture which lodges upon the Surface of their Leaves in the Night, and not only retards the Fruit, but renders it ill-taſted and watry.

The Soil under theſe Trees ſhould alſo be every Year well dug and manured, tho' there will ſcarce any Sort of Plants grow under them; but it is of great Advantage to the Fruit, notwithſtanding what may have been ſaid to the contrary.

The *White Mulberry* is commonly cultivated for its Leaves, to feed *Silk-worms*, in *France*, *Italy*, &c. tho' the *Perſians* always make uſe of the common *Black Mulberry* for that Purpoſe; and I have been aſſured by a Gentleman of Honour, who hath made Trial of both Sorts of Leaves, that the Worms fed with thoſe of the Black Sort, produce much better Silk than thoſe fed with the White; but he obſerves, that the Leaves of the Black Sort ſhould never be given to the Worms, after they have eaten for ſome Time of the White, leſt the Worms ſhould burſt, which is often the Caſe when they are thus treated.

The Trees which are deſign'd to feed Silk-worms, ſhould never be ſuffer'd to grow tall, but rather kept in a Sort of Hedge, and inſtead of pulling off the Leaves ſingly, they ſhould be ſhear'd off together with their young Branches, which is much ſooner done, and not ſo injurious to the Tree.

This white Sort may be propagated either from Seeds or Layers, as the *Black Mulberry*, and is equally as hardy: There are two or three Varieties of this Tree, which differ in the Shape of their Leaves, Size, and Colour of their Fruit; but as they are of no other Uſe than for their Leaves, ſo the ſtrongeſt ſhooting and the largeſt-leav'd Sort ſhould be preferr'd.

The *Large-leav'd Virginian* Sort, with long red Fruit, is at preſent very ſcarce in *England*, tho' it ſeems to be the common Sort, which grows ſpontaneouſly in the Woods of *America*: This may be propagated from Seeds, or by laying down the Branches, as the common Sort; it is very hardy, and will endure the Cold of our Winters in the open Air very well. The Leaves of this Kind are very large, and ſeem to be as proper for feeding of Silk-worms as thoſe of the common Sort; ſo that if ever the Project of eſtabliſhing a *Silk Manufactory* in the *Weſt-Indies* ſhould be ſet on foot, there would be no Occaſion of their ſending over for *Mulberry-trees*, as hath been by ſome propos'd, ſince they will find a ſufficient Quantity in all the Woods of that Country.

The *Large-leav'd Virginian Mulberry* with black Shoots, is ſtill more uncommon than any of the former: There is a large Plant of this Kind growing in the Gardens of the Biſhop of *London* at *Fulham*, which has been ſeveral Years an Inhabitant of that Garden, but has never produced any Fruit, that I could learn, but hath ſome Years a great Number of *Katkins*, much like thoſe of the *Hazel-Nut*, which occaſion'd Mr. *Ray* to give it the Name of *Corylus*; but it may be one of the Male Trees, which never produces Fruit, as it ſometimes happens in the common Sorts of *Mulberries*, the Leaves being very like thoſe of the *Black Mulberry*, but ſomewhat larger and rougher.

This Tree has not been propagated yet in this Country, for tho' it has been budded and grafted upon both the *Black* and *White Mulberries*, yet I can't hear that it hath ſucceeded upon either; and the Tree, being pretty tall, can't be laid down, which is the moſt likely Method to propagate it: This is very hardy, and will endure the Cold of our Climate in the open Air very well, and is coveted as a Curioſity by ſuch who delight in the Variety of Trees and Shrubs.

MOSCHATELLINA, Tuberous Moſchatel.

The *Characters* are;

It hath a Flower conſiſting of one Leaf, which is divided at the Brim into many Parts, from whoſe Cup ariſes the Pointal, fixed like a Nail in the Middle of the Flower, which afterward becomes a ſoft ſucculent Berry, in which are contained many flat Seeds.

We have but one Sort of this Plant, *(viz.)*

MOSCHATELLINA *foliis fumariæ bulboſæ.* *J. B.* Moſchatel with Leaves like thoſe of the bulbous Fumitory.

This Plant grows wild in ſhady moiſt Places in ſeveral Parts of *England*; it flowers the Latter-end of *March*, or the Beginning of *April*, and the Leaves decay about the Middle of *June*, when the Roots may be taken up and tranſplanted. Theſe ſhould have a pretty ſtrong Soil, and if they are planted under Thickets of Shrubs, they will thrive much better than in an open Expoſure. The Flowers are of a greeniſh white Colour, ſo are not very beautiful, but as the Plants will thrive under Trees, and require no Care in their Culture, ſo they may have a Place in Gardens for the ſake of Variety.

MOSS. *Vide* Muſcus.

MOTHERWORT. *Vide* Cardiaca.

MOULD, the Goodneſs of which may be known by the Sight, Smell, and Touch.

Firſt, by the *Sight*. Thoſe *Moulds* that are of a bright *Cheſnut* or *Hazelly* Colour are accounted the beſt; of this Colour are the beſt Loams, and alſo the beſt natural Earth; and this will be the better yet, if it cut like Butter, and does not ſtick obſtinately, but is ſhort, tolerably light, breaking into ſmall Clods, is ſweet, will be tempered without cruſting or chapping in dry Weather, or turning to Mortar in wet.

The next to that, the dark-grey and ruſſet *Moulds* are accounted the beſt, the light and dark Aſh Colour are reckon'd the worſt, ſuch as are uſually found on common or heathy Ground; the clear tawney is by no means to be approved but that of a yellowiſh red Colour is accounted the worſt o all; this is commonly found in wild and waſte Parts of th Country, and, for the moſt part, produce nothing but *Goſs*, *Furz*, and *Fern*, according as their Bottoms are more or leſ of a light and ſandy, or of a ſpewy Gravel or clayey Nature.

Secondly, by the *Smell*. All Lands that are good and wholeſome, will, after Rain or breaking up by the Spade, emit good Smell.

Thirdly, by the *Touch*. By this Means we may diſcove whether it conſiſts of Substances intirely arenaceous or clam my, or, according as it is expreſs'd by Mr. *Evelyn*, whether it be tender, fatty, deterſive, or ſlippery, or more harſh, gritty, porous, or friable.

That being always the beſt that is between the two Extreams, and does not contain the two different Qualities of ſoft and hard mix'd, of moiſt and dry, of churliſh and mild; that is, neither too unctuous or too lean, but ſuch as will eaſily diſſolve, of a juſt Conſiſtence, between Sand and Clay, and ſuch as will not ſtick to the Spade or Fingers upon every Flaſh of Rain.

A *Loam* or *Brick Mould* is not to be diſapprov'd, as requiring little Help or Improvement but the Spade, and is eſteemed both by the Gardener and Floriſt.

MUCILAGE, is a viſcous, clammy Subſtance about Seeds, *&c.*

MUCILAGINOUS, ſignifies endow'd with a clammy viſcous Matter.

MULBERRY. *Vide* Morus.

MULLEIN. *Vide* Verbaſcum.

MULTISILIQUOUS Plants, are ſuch as have after each Flower many diſtinct, long, ſlender, and, many times, crooked Caſes or *Siliquæ*, in which their Seed is contain'd; and which, when they ripen, open of themſelves, and let their Seeds drop. Of this Kind is the *Bear's-foot*, *Columbines*, common *Houſe-leek*, *Navel-wort*, *Orpine*, &c.

MUMMY, a ſort of Grafting-wax, made of one Pound of common Black Pitch, and a quarter of a Pound of common Turpentine, put into an earthen Pot and ſet on the Fire in the open Air; in doing this you ought to hold a Cover in your Hand, ready to cover it, in order to quench it, by putting it thereon, which is to be done ſeveral times, ſetting it on the Fire again, that the nitrous and volatile Parts may be evaporated. The Way to know when it is enough, is, by pouring a little of it upon a Pewter Plate, and if it be ſo, it will coagulate preſently; then this melted Pitch is to be poured into another Pot, and a little common Wax is to be added to it, mixing them well together; and then to be kept for Uſe.

Dr. *Agricola* directs the uſing this *Mummy* as follows:

When you would dreſs Roots with this Wax, you muſt melt it, and afterwards let it cool a little, then dip in the Ends of the Pieces of the Roots you would plant (for he propoſes it for the planting of Pieces of Roots of Trees, *&c.*) one after the other, but not too deep, and afterwards to put them in Water, and to plant them in the Earth, the ſmall End downwards, ſo that the larger End may appear a little Way out thereof, and have the Benefit of the Air; and then to preſs the Earth very hard down about them, that they may not receive too much Wet, becauſe that would rot them.

Mummy for Exotick Plants: The ſame Author directs the making it as follows:

Take half a Pound of Gum-Copal, beat it very fine, and ſearſe it; take three Pounds of *Venice* Turpentine, and melt it over a ſlow Fire in a ſtrong earthen Pot; when the Turpentine is melted and liquidated, put the ſifted Gum into it, keep it continually ſtirring with a little Stick, augmenting the Fire gradually, and it will all diſſolve inſenſibly; afterwards let the Turpentine evaporate well, and it will thicken; and when it is become of a ſufficient Conſiſtence, you may make it up into little Rolls, like Sealing Wax, and keep it for Uſe.

This *Mummy*, he ſays, is an excellent Vulnerary for Plants, it being ſubject to no Corruption, as other gummy Things are; it hinders any Rottenneſs between the Stock and the Root, by means of which the *Callus* is form'd the ſooner, and ſpreads over all the Parts, and the Stock becomes intirely connected with the Root. It alſo gives Strength and Vigour to the Root, and likewiſe facilitates it.

Vegetable Mummy: The ſame Author directs the making of this as follows:

Fill a large Kettle or earthen Pot about a third Part full of common Black Pitch, and add to it a little fine Roſin, or ſulphurated Pitch, and a little yellow Wax; melt theſe together till they become liquid, then take them off the Fire, and let them ſtand till they have done ſmoaking, and when cool, you may, with a Bruſh, plaiſter the Inciſions which are made for Inoculation, Grafting, *&c.*

Garden or *Foreſt Mummy:* The ſame Author directs the making it as follows:

Take three Pounds of common Turpentine, and four Pounds of common Pitch, melt the Turpentine over the Fire, and having beaten the Pitch to a Powder, throw it in; when they are well mix'd together, and grown pretty thick, take it off and keep it for Uſe.

This Compoſition may be either made up into little Sticks, like thoſe of Sealing-Wax, to be made uſe of on little Trees, or it may be kept in little Pots, and melted over a ſlow Fire, when there is Occaſion to uſe it; and dipping a little Bruſh in it you may plaiſter the Graft.

The *Noble Mummy*, or *Grafting Wax:* To make this the ſame Author directs:

Take two Pounds of pure Pitch, ſuch as is call'd at *Ratiſbonne*, *Virgin Pitch*, and add to it half a Pound of good Turpentine; put them together in an earthen Pot, and ſet them over the Fire, that the volatile Part of the Turpentine may evaporate, otherwiſe it would be very prejudicial to Trees and Roots: Prove it as you did the former, to know when it is enough, then add to it half a Pound of Virgin-Wax, and half an Ounce of pounded Myrrh and Aloes; when theſe are well mix'd, make it up into little Rolls, or Plaiſters; or elſe it may be kept in Gally-pots.

The Time he directs when the Operation of the Roots is to be performed, is in the Months of *September*, *October*, and *November*; tho' it may ſucceed well at any Time of the Year, yet thoſe Months are the moſt proper Seaſons for it. The only Difference, he ſays, is, what is planted in the Spring will ſhoot out in *June* or *July*, and what is planted in Autumn comes not forth till the Month of *April*.

The aforeſaid Author mentions great Performances by uſing theſe *Mummies*; thoſe who have a mind to be ſatisfied may peruſe his Treatiſe.

MUNTINGIA.

The *Characters* are;

It hath a Roſe-ſhaped Flower, conſiſting of ſeveral Leaves, which are placed in a circular Order, from whoſe Cup ariſes the Pointal, which afterward becomes a globular ſoft fleſhy umbilicated Fruit, in which are contained many ſmall Seeds.

The *Species* are;

1. MUNTINGIA *folio ſericeo, molli fructu majori. Plum. Nov. Gen.* Muntingia with a ſoft ſilky Leaf, and a larger Fruit.
2. MUNTINGIA *folio ulmi aſpero, fructu minimo glomerato. Plum. Nov. Gen.* Muntingia with a rough Elm-leaf, and the leaſt Fruit growing in Cluſters.
3. MUNTINGIA *folio corni, fructu minore. Plum. Nov. Gen.* Muntingia with a cornel Leaf, and a leſſer Fruit.

Theſe Plants all of them grow in *Jamaica*, and ſeveral other Parts of *America*. They were diſcovered by Father *Plumier*, who gave them the Name from Dr. *Muntingius*, who was Profeſſor of *Botany* at *Groningen* in *Holland*, ſo that we have no *Engliſh* Name for them.

They may be propagated by Seeds, which ſhould be ſown in Pots filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners Bark, where they ſhould be duly watered, and in warm Weather the Glaſſes ſhould be raiſed to admit freſh Air. Theſe Seeds will often remain in the Ground a whole Year, before the Plants will appear; in which Caſe the Pots muſt be kept conſtantly clear from Weeds, and ſhould remain in the Hot-bed till after *Michaelmas*, when they may be removed into the Stove, and plunged into the Bark-bed, between other Pots of tall Plants, under which they will ſtand very well, ſo may be crowded in where Plants will not thrive. During the Winter Seaſon, the Pots ſhould be now and then watered, when the Earth appears dry; and in the Beginning of *March*, the Pots ſhould be removed out of the Stove, and placed into a freſh Bark-bed under Frames, which will bring up the Plants in a ſhort Time after.

When the Plants are come up about two Inches high, they ſhould be carefully taken out of the Pots, and each planted into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to ſhade them from the Sun, until they have taken new Root, after which Time they ſhould be duly watered, and in warm Weather muſt have a large Share of freſh Air. In this Hot-bed the Plants may remain until the Autumn, when the Nights begin to be cold, when they ſhould be removed into the Stove, and plunged into the Bark-bed. During the Winter-ſeaſon theſe Plants muſt be kept warm, (eſpecially while they are young) and they muſt be frequently refreſhed with Water; but it muſt not be given to them in large Quantities at this Seaſon, leſt it rot the tender

Fibres of their Roots. It will be proper to continue theſe Plants in the Stove all the Year; but in warm Weather they ſhould have a large Share of Air, and Plenty of Water; but as the Plants grow in Strength, ſo they will be more hardy, and may be more expoſed in Summer, and in Winter will live in a dry Stove, if kept in a moderate Degree of Heat.

The firſt of theſe Plants riſeth to the Height of thirty Feet or more in the Places of its natural Growth, and divides into many Branches at the Top; the Flowers are white, having ſeveral yellow Threads in each; the Fruit is about the Size of a Cherry, and ſhaped like a Pomegranate, and, when ripe, of a brown Colour.

The other two Sorts ſeldom grow above twelve or fourteen Feet high, and put out many Branches on their Sides. The Fruit of theſe are ſmall, and of an Orange Colour.

MURUCUIA.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of ſeveral Leaves, which are placed in a circular Order, which is incloſed in a many-leav'd Cup. The Middle of the Flower is occupied by a Tube, ſhaped like the Trunk of a Cone; out of which ariſes the Pointal, with the Embryo on the Top, on which reſt three Clubs or Nails, and under them the Stamina. The Embryo afterward becomes a fleſhy oval Fruit, having one Cell, which is filled with Seeds, which are covered with a Hood or Veil.

There is but one *Species* of MURUCUIA, which is;

MURUCUIA *folio lunato. Inſt. R. H.* Murucuia with a horned Leaf.

This Plant is very nearly allied to the Paſſion-flower, and is by ſome Authors ranged with them; but as it differs from them in the Structure of the Flower, having a large Trunk in the Center of the Flower, which the Paſſion-flowers have not, ſo Dr. *Tournefort* has ſeparated it from them, and applied this Name to it, which is the *American* Name given to ſeveral Sorts of Paſſion-flowers.

It grows in *Jamaica*, and ſeveral other Places in the hotteſt Parts of *America*, from whence the Seeds may be procured. Theſe Seeds ſhould be ſown early in the Spring of the Year, on a moderate Hot-bed; and when the Plants are come up, they muſt be tranſplanted each into a ſeparate ſmall Pot, and plunged into a Hot-bed of Tanners-bark, and then managed in the ſame Manner as hath been directed for the tender Sorts of Paſſion-flowers, with which this Plant will thrive, and produce its beautiful Flowers every Year in Plenty.

MUSA, The Plantain-Tree.

The *Characters* are;

Muſa *is a Kind of Plant with a polypetalous, anomalous Flower; the upper Petal is excavated or hollowed like a little Boat, and divided into three at the Summit; the hither one is concave, but the inward one pellated, or in the Form of a Creſcent or Half-moon Shield, and accompanied with two little narrow-pointed Leaves; the Calyx paſſes into a Cucumber-ſhaped Fruit, that is ſoft, fleſhy, covered with a Skin, divided, as it were, into three Loculaments, in which there appear, as it were, ſome Rudiments of Seeds.*

The *Species* are;

1. MUSA *fructu cucumerino longiori. Plum. Nov. Gen.* The Plantain-tree, *vulgo*.
2. MUSA *caudice maculato, fructu recto rotundo breviore odorato. Sloan. Cat.* The Banana-tree, *vulgo*.

Theſe Plants are very common in the *Eaſt* and *Weſt-Indies*, as alſo in moſt hot Countries of the World. They are carefully cultivated by the Planters in the *Weſt-Indies*, who plant 'em in low, rich Ground, by the Sides of Gullies, where they produce Fruit moſt Parts of the Year. In *England* they are only preſerved as Curioſities, where they muſt be conſtantly kept in a Bark-Stove; for tho' they may be kept alive in another warm Stove, yet they will make very little Progreſs therein, and do not appear half ſo beautiful, their chief Ornament being the Largeneſs of their Leaves, which are ſometimes ſix Feet long, and near two Feet broad; but as theſe Plants take up a great deal of Room in the Stove, eſpecially when they arrive to a conſiderable Size, ſo it is not convenient to keep more than one Plant of each Kind.

During the Summer-ſeaſon theſe Plants muſt be plentifully water'd, for the Surface of their Leaves being large, occaſions a great Conſumption of Moiſture, by Perſpiration, in hot Weather; but in the Winter they muſt be water'd more ſparingly, tho' at that Seaſon they muſt be often refreſh'd, but it muſt not be given 'em in ſuch Quantities.

The Pots in which theſe Plants are placed ſhould be large, in proportion to the Size of the Plants, for their Roots generally extend pretty far; and the Earth ſhould be rich and light. The Degree of Heat with which theſe Plants thrive beſt, is much the ſame with the *Anana* or *Pine-Apple*.

Theſe Plants are eaſily propagated, by cutting off an old Plant near the Ground, which will occaſion their ſhooting out ſeveral young ones from the Root; which is the manner they are propagated in the hot Countries; ſo that after a Spot of Ground is once planted with 'em, they will continue ſeveral Years; for the old Plant producing one large Bunch of Fruit from the Center, when that is ripe and cut off, the whole Plant decays, and ſeveral young ones ſpring up from the Roots, which being produced one after another, ſucceſſively, affords the Inhabitants Plants of various Size and Age, which produce their Fruit ſucceſſively, in like manner.

It is the firſt of theſe Species which is chiefly cultivated in the *Weſt-Indies*; that, producing a much larger Bunch of Fruit, is by the Inhabitants greatly preferr'd to the other, which is accounted a very pleaſant Fruit, when ripe, and is by many Perſons greatly coveted by way of Deſert, being ſofter and more luſcious to the Taſte, but is not ſo much eſteem'd for Food.

Theſe Plants do riſe to be fifteen or twenty Feet high in the *Weſt-Indies*, to which Height they generally arrive in about ten Months from their firſt planting, ſoon after which they produce their Fruit and then decay: They are of the quickeſt Growth of any Vegetable yet known. Sir *Hans Sloane* ſays, one may almoſt ſee them grow; he cut a young Tree even at the Top with a Knife, which immediately grew up diſcernably, and in an Hour's Time the middle Leaves, which were wrapped up within the others, were advanced above them half an Inch.

There have been lately ſeveral of theſe Plants in Flower and Fruit, in ſeveral Parts of *Europe*. The firſt of theſe Kinds, which produced Fruit in *England*, was in the Garden of Sir *Joſeph Ayloffe*, Bart. near *Harrow*: Which was of that Sort with longer Fruit, commonly called the *Plantain-Tree*. This Plant grew above twenty Feet high, and at fourteen Feet from the Surface of the Bark-bed, was produced the Bunch of Fruit from between the Leaves, which was about four Feet in Length, and weighed above forty Pounds. Theſe Fruit grew to a large Size, and became of a pale yellow Colour in Autumn, which is the Sign of Ripeneſs; but it was an ill-flavoured Fruit, as I am informed it is in the native Places of its Growth.

Since this there have been ſome other of theſe Plants in Fruit in *England*; one was at Mr. *Blackbourn*'s in *Lancaſhire*; and two Plants; one of each Kind hath produced Fruit in the *Phyſick-Garden* at *Chelſea*. The moſt ſure Method to have theſe Plants fruit in *England*, is, after they have grown for ſome Time in Pots, ſo as to have made good Roots, to ſhake them out of the Pots with the Ball of Earth to their Roots, and plant them into the Tan-bed in the Stove, obſerving to lay a little old Tan near the Roots, for their Fibres to ſtrike into; and in few Months the Roots of theſe Plants will extend themſelves many Feet each Way in the Bark, and theſe Plants will thrive a great deal faſter, than thoſe which are confined in Pots or Tubs. When the Bark-bed wants to be renewed with freſh Tan, there ſhould be great Care taken of the Roots of theſe Plants, not to cut or break them, as alſo to leave a large Quantity of the old Tan about them, becauſe, if the new Tan is laid too near them, it will ſcorch their Roots, and injure them. Theſe Plants muſt be plentifully ſupplied with Water, otherwiſe they will not thrive; in Winter they ſhould be watered every other Day, giving at leaſt a Gallon to each Plant; but in Summer they muſt be watered every Day, and double the Quantity given to them each Time. If the Plants puſh out their Flower-ſtems in the Spring, there will be Hopes of their perfecting their Fruit; but when they come out late in the Year, the Plants will decay before the Fruit is ripe. The Stoves in which theſe Plants are placed, ſhould be at leaſt twenty-four Feet in Height; otherwiſe there will not be room for their Leaves to expand: For when the Plants are in Vigour, the Leaves are often eight Feet in Length, and near three Feet broad; ſo that if the Stems grow to be ſixteen Feet, to the Diviſion of the Leaves, if the Houſe is not twenty-four Feet high, the Leaves will be cramp'd, which will retard the Growth of the Plants.

MUSCARI, Muſk, *or* Grape Hyacinth, *vulgo*.

The *Characters* are;

It hath a bulbous Root, the Leaves are long and narrow, the

Flower is hermaphroditical, conſiſting of one Leaf, and ſhaped like a Pitcher, and cut at Top into ſix Segments which are reflex'd; the Ovary becomes a triangular Fruit, divided into three Cells, which are full of round Seeds.

The *Species* are;

1. Muscari *arvenſe, juncifolium minus cæruleum. Tourn.* Common leſſer blue Grape-flower, or Muſcary.
2. Muscari *arvenſe, juncifolium exalbidum minus. Tourn.* Leſſer whitiſh Grape-flower, or Muſcary.
3. Muscari *obſoletiore, flore ex purpura virente. Cluſ.* Muſk Hyacinth or Grape-flower, of a worn-out purple-greeniſh Colour.
4. Muscari *cæruleum majus. Tourn.* Greater blue Muſcary or Grape-flower.
5. Muscari *arvenſe, latifolium purpuraſcens. Tourn.* Broad-leav'd Muſcary or Grape-flower, with a purpliſh Flower.
6. Muscari *panicula comoſa purpuro-violacea. Boerh. Ind.* The feather'd Hyacinth, *vulgo.*

There are ſome other Varieties of this Plant which are preſerv'd in the curious Flower-Gardens in *Holland* and *Flanders*, but thoſe here mention'd are what I have obſerv'd in the *Engliſh* Gardens.

The firſt Sort is very common in moſt old Gardens, where, by its plentiful Increaſe, it is become ſo troubleſome as to render it little eſteem'd; for when once theſe Roots have taken Poſſeſſion of a Garden, they are ſcarcely ever eradicated afterward; the ſmalleſt Off-ſets growing, altho' they are buried a Foot under the Surface of the Ground. This produces its Flowers in *April* and *May*, and if permitted to remain, will produce ripe Seeds in *June*.

The ſecond Sort is leſs common than the firſt, and is preſerved by ſuch who are curious in Flowers, tho' it is a Plant of no great Beauty; this is propagated by Off-ſets, as the common *Hyacinth*, and will thrive in almoſt any Soil or Situation, but beſt in that which is warm and dry.

The third Sort is a very deſpicable Flower, to Appearance, but is chiefly preſerv'd for its uncommon Sweetneſs; this is alſo increas'd, as the former, and produces its Flowers much about the ſame Seaſon.

The fourth, fifth, and ſixth Sorts are alſo preſerved in curious Gardens for Variety, but neither of theſe have much Sweetneſs in their Flowers; theſe are alſo propagated by Off-ſets as the former, but produce their Flowers later in the Seaſon.

The proper Seaſon for taking up the Roots of theſe Flowers is in *June*, when their Leaves are decay'd; at which Time they ſhould be ſpread upon Mats, in a dry Place, for a Fortnight, until their Bulbs be dry'd, when they may be laid up, each Sort by itſelf, until the Beginning of *October*, which is the Seaſon for planting moſt of thoſe bulbous-rooted Flowers; and the various Sorts of theſe may then be intermix'd amongſt other Flowers of the ſame Growth, where, in the Seaſon of their flowering, they afford an agreeable Variety. Theſe Roots ſhould never be permitted to remain longer than two Years unremoved, for they multiply ſo faſt, that the Number of their Off-ſets would greatly weaken the blowing Roots, and cauſe their Flowers to be very ſmall; and the firſt Sort, which increaſes ſo plentifully, would fill the Borders with Off-ſets, ſo as not to be clear'd out again.

MUSCIPULA. *Vide* Lychnis.

MUSCOSE, MUSCOSUS; Moſſy, or abounding with Moſs.

MUSCOSITY; Moſſineſs.

MUSCUS; Moſs.

Theſe, tho' formerly ſuppos'd to be only Excreſcencies produced from the Earth, Trees, *&c.* yet are no leſs perfect Plants than thoſe of greater Magnitude, having Roots, Branches, Flowers, and Seeds, but yet cannot be propagated from the latter by any Art.

The Botaniſts diſtinguiſh theſe into ſeveral *Genera*, under each of which are ſeveral Species; but as they are Plants of no Uſe or Beauty, ſo it would be to no purpoſe to enumerate them in this Place.

Theſe Plants chiefly flouriſh in cold Countries, and in the Winter-ſeaſon, and are many Times very injurious to Fruit-trees, which grow upon cold, barren Soils, or where they are ſo cloſe planted as to exclude the free Acceſs of Air: The only Remedy in ſuch Caſes is to cut down Part of the Trees, and plough up the Ground between thoſe left remaining, and in the Spring of the Year, in moiſt Weather, you ſhould, with an Iron Inſtrument, made a little hollow, the better to ſurround the Branches of the Tree, ſcrape off the Moſs, carrying it off the Place; and by two or three Times thus cleanſing them, together with carefully ſtirring the Ground, it may be entirely deſtroy'd from the Trees: But if you do not cut down part of the Trees, and ſtir the Ground well, the rubbing off the Moſs will ſignify little, for the Cauſe not being remov'd, the Effect will not ceaſe, but the Moſs will, in a ſhort Time, be as troubleſome as ever.

MUSHROOMS; are, by many Perſons, ſuppos'd to be produc'd from the Putrefaction of the Dung, Earth, *&c.* in which they are found; but notwithſtanding this Notion is pretty generally received amongſt the unthinking Part of Mankind, yet, by the curious Naturaliſts, they are eſteem'd perfect Plants, tho' their Flowers and Seeds have not, as yet, been diſcover'd. But ſince they may, and are annually propagated by the Gardeners near *London*, and are (the eſculent Sort of them) greatly eſteem'd, by moſt curious Palates, ſo I ſhall briefly ſet down the Method practis'd by the Gardeners who cultivate them for Sale.

But, firſt, it will not be improper to give a ſhort Deſcription of the true eatable Kind, ſince there are ſeveral unwholeſome Sorts which have been, by unſkilful Perſons, gather'd for the Table.

The true *Champignon*, or *Muſhroom*, appears at firſt of a roundiſh Form, like a Button, the upper Part of which, as alſo the Stalk, is very white, but being open'd, the under Part is of a livid Fleſh-colour, but the fleſhy Part, when broken, is very white: When theſe are ſuffer'd to remain undiſturb'd, they will grow to a large Size, and explicate themſelves almoſt to a Flatneſs, and the red Part underneath will change to a dark Colour.

In order to cultivate them, if you have no Beds in your own, or in neighbouring Gardens, which produce them, you ſhould look abroad in rich Paſtures, during the Months of *Auguſt* and *September*, until you find 'em (that being the Seaſon when they are produced) then you ſhould open the Ground about the Roots of the *Muſhrooms* where you will find the Earth, very often, full of ſmall white Knobs, which are the Off-ſets or young *Muſhrooms*; theſe ſhould be carefully gather'd, preſerving them in Lumps with the Earth about them; then being provided with a Parcel of new Horſe-dung, you ſhould ſhake out the Litter, if there be any amongſt it, and caſt it up into a Heap, for ſeven or eight Days, to heat; then you ſhould dig a Trench about three Feet wide, and in Length, according to the Quantity of *Muſhrooms* required, or the Plenty of Earth you can procure for that Purpoſe, into which you ſhould lay the Dung about a Foot thick, covering it over with light rich Earth, about ſix or eight Inches, into which, on each Side, you ſhould put in ſome of the Knobs of *Muſhroom* Earth, about ſix Inches aſunder.

Then make another Layer of Dung upon this Earth, as before, about eight or ten Inches thick, obſerving to draw in the Sides, ſo as not to bury the Knobs of *Muſhroom* Earth above half an Inch; then put another Laying of Earth, placing ſome Knobs on the Sides, as before, and put a third Laying of Dung thereon, ſtill drawing it in narrower, and cover this with Earth, ſo as to bring it to a Ridge, ſtill placing ſome Knobs of the *Muſhroom* Earth into the Sides, all the Way up; then cover the Bed all over with dry Litter, about half a Foot thick, to prevent the Earth from drying too faſt, as alſo to keep out the Wet, if there ſhould happen to be Rain; and this Litter will retain the moiſt Vapour which ariſes from the Fermentation of the Dung, and is of great Service in promoting the Growth of the *Muſhrooms*; for it is obſerved, that too much Drowth or over Moiſture is deſtructive to them, but a *Medium* between both is abſolutely neceſſary for their Production.

When your Bed has been made a Fortnight, you muſt carefully look over it, (by drawing off the Litter with your Hands) to ſee if the *Muſhrooms* begin to appear; for if they are permitted to remain long in the Bed after they are large enough for Uſe, they will rot, and infect all the young Spawn, or Off-ſets, ſo that all that Part of the Bed where they rot, will be intirely ſpoil'd. After they once begin to produce, the Bed muſt be diligently ſearch'd every Day, during their chief Seaſon of Growth, which is commonly in *Auguſt* and *September*, but at other Times, every other Day, in order to gather all ſuch as are fit for Uſe; in doing of which you ſhould pull them gently out of the Ground, ſo that no Part of their Stems be left behind, which will engender Worms, whereby the young Spawn will be deſtroy'd; but if in pulling them up, there ſhould any of the Spawn adhere to their Roots, that ſhould be gently taken off, being careful not to bruiſe it, and thruſt into the Bed again, where it will ſoon fix.

As the Cold increaſes in Autumn, ſo you ſhould increaſe the Quantity of your Litter over the Beds, to preſerve 'em from that and Wet, which, if not guarded againſt, will ſoon retard the Growth of the *Muſhrooms*, and ſpoil the Beds for a future Crop.

A Bed thus manag'd, if the Spawn takes kindly, will continue good for ſeveral Months, and produce great Quantities of *Muſhrooms*; from theſe Beds you take the Spawn for a freſh Supply, which may be laid up in a dry Place until the proper Seaſon of uſing it, which is toward the latter End of *July* or the Beginning of *Auguſt*, and it will be the better for the Purpoſe, if kept dry three or four Months, as I have experienc'd; nay, I have had it ſucceed extremely well, after having been kept in a warm dry Place above ſix Months.

MUSTARD. *Vide* Sinapi.

MYAGRUM, Gold of Pleaſure.

The *Characters* are;

It hath a Flower conſiſting of four Leaves, which are placed in form of a Croſs, out of whoſe Cup ariſes the Pointal, which afterwards becomes a turbinated Fruit, having one Cell, in which are included an oblong Seed, and two empty Cells at the Point.

The *Species* are;

1. Myagrum *monoſpermum latifolium. C. B. P.* Broad-leaved one-grain'd Gold of Pleaſure.
2. Myagrum *monoſpermum minus. C. B. P.* Leſſer one-grained Gold of Pleaſure.
3. Myagrum *capitulis rotundis. J. B.* Round-podded Gold of Pleaſure.

Theſe are all of them annual Plants, which periſh ſoon after their Seeds are ripe. They grow wild in the Corn-fields, in ſeveral Parts of *Europe*, where if the Seeds are permitted to ſcatter, the Plants will come up and thrive better than thoſe which are ſown with Care; ſo that the beſt Way to continue theſe Species, is to let the Seeds fall in Autumn, or to ſow them ſoon after they are ripe; for when they are ſown in the Spring, they very often miſcarry. When the Plants are come up, they ſhould be cleared from Weeds; and where they are too cloſe together, they ſhould be thinned ſo as to leave them about eight or ten Inches aſunder, which is all the Culture they require.

The Oil of theſe Seeds is much uſed in *Germany*, where the Inhabitants ſow large Fields with the Seed. This Oil is frequently uſed in Medicine, but the poor People eat the Oil in Sallads and Sauces, and the Rich uſe the Oil for their Lamps; but in *England* it is very rarely uſed either Way.

MYOSOTIS: [of μυὸς, a *Mouſe*, and ὦτα, an *Ear*] Mouſe-ear Chickweed.

The *Characters* are;

It hath the whole Appearance of Chickweed; but the Flower is larger, and the Fruit is ſhaped like an Ox's-horn, gaping at the Top, and full of ſmall round Seeds.

The *Species* are;

1. Myosotis *Hiſpanica ſegetum. Tourn.* Spaniſh Corn Mouſe-ear Chickweed.
2. Myosotis *Alpina latifolia. Tourn.* Broad-leav'd Mouſe-ear Chickweed of the *Alps*.
3. Myosotis *orientalis perfoliata, folio lychnidis. Flor.* Eaſtern Thorough-wax, Mouſe-ear Chickweed, with a Campion Leaf.

There are ſeveral other Varieties of this Plant, which are preſerved in curious Botanick Gardens; but as they are of little Beauty or Uſe, ſo I ſhall omit mentioning them in this Place. Theſe may be propagated by ſowing their Seeds in *March*, upon a Bed of light freſh Earth, in an open Situation, where they may remain to flower and ſeed, being careful to clear them from Weeds, as alſo to pull up the Plants, where they come up too thick; but they do not ſucceed well if tranſplanted, ſo that they ſhould always remain where they are ſown.

MYRRHIS; [is ſo call'd, becauſe it has the Scent of *Myrrh*] Sweet Cicely.

The *Characters* are;

It is an umbelliferous Plant, with a Roſe-ſhap'd Flower, conſiſting of ſeveral unequal Petals, or Flower Leaves, that are placed circularly, and reſt upon the Empalement; which turns to a Fruit, compos'd of two Seeds, reſembling a Bird's-bill, channell'd and gibbous on one Side, but plain on the other.

The *Species* are;

1. Myrrhis *magno ſemine longo ſulcato. J. B.* Sweet Cicely, *or* Great ſweet Chervil, and by ſome ſweet Fern.
2. Myrrhis *annua, ſemine ſtriato villoſo incano. M. Umb.* Annual ſweet Cicely, with hairy ſtriated Seeds, by ſome call'd Candy Carrot.
3. Myrrhis *orientalis, folio anguſtiori peucedani ſemine villoſo. Boerh. Ind.* Eaſtern ſweet Cicely, with a narrow ſulphur-wort Leaf and hairy Seeds, *or* the True Candy Carrot.

There are many more Sorts of this Plant preſerved in the Gardens of ſuch as are curious in Botany, but as they are Plants of little Uſe or Beauty, ſo I thought it not neceſſary to enumerate 'em in this Place.

The firſt mention'd is an abiding Plant, which is ſometimes uſed in Medicine: This may be propagated by ſowing the Seeds in *February*, upon a Bed of light rich Earth, in a ſhady Situation; and when the Plants come up they ſhould be tranſplanted out into the like rich Earth, in a moiſt ſhady Situation, at about two Feet aſunder; for they ſpread very wide, and take up much Room, eſpecially if they are permitted to remain two or three Years unremoved); after the Plants have taken Root they will require no further Care, but to keep 'em clear from Weeds, and they will endure ſeveral Years, and produce great Quantities of Seeds, by which, as alſo by parting the old Roots, they may be greatly increas'd.

The Seeds of the ſecond Sort are moſt commonly ſold in the Shops for thoſe of the *Daucus Creticus*; but it is the third Sort which is generally accounted the true *Daucus Creticus*: The Seeds of which are us'd in ſome of the capital Medicines of the Shops.

Theſe may be propagated by ſowing their Seeds in the Spring upon a Border of light Earth, expos'd to the Morning Sun, in which the Plants will riſe in about ſix Weeks after; when they may be tranſplanted out into Beds of light Earth, obſerving to water and ſhade them until they have taken Root; after which they will require no farther Care but only to keep them clear from Weeds: The Summer following theſe Plants will produce Flowers and Seeds; ſoon after which, the ſecond Sort will decay; but the third will ſometimes abide two or three Years, and produce Seeds annually.

MYRTUS; [according to ſome Authors, was ſo call'd on account of the Likeneſs of its Scent to that of *Myrrh*; but others will have it derive its Name of *Myrrha*, an *Athenian* Damſel, with whom *Pallas* being enamour'd, after her Death is ſaid to have transform'd her into this Tree] The Myrtle.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves diſpos'd in a circular Order, which expand in Form of a Roſe; *upon the Top of the Footſtalk is the Ovary, which has a ſhort Star-like Cup, divided at the Top into five Parts, and expanded; the Ovary becomes an oblong umbilicated Fruit, divided into three Cells, which are full of Kidney-ſhap'd Seeds.*

The *Species* are;

1. Myrtus *communis Italica. C. B. P.* Common Myrtle, with pretty large Leaves.
2. Myrtus *latifolia Romana. C. B. P.* Common broad-leav'd Myrtle.
3. Myrtus *minor vulgaris. C. B. P.* Thyme-leav'd Myrtle, *vulgo*.
4. Myrtus *folio Buxi. Schuyl. Boerh. Ind.* Box-leav'd Myrtle, *vulgo*.
5. Myrtus *foliis minimis & mucronatis. C. B. P.* Roſemary-leav'd Myrtle, *vulgo*.
6. Myrtus *flore pleno. Corn.* Double-flowering Myrtle, *vulgo*.
7. Myrtus *foliis odore nucis moſchatæ, cauliculis rubentibus, vulgo odore Citri. Schuyl. Boerh. Ind.* The Nutmeg Myrtle, *vulgo*.
8. Myrtus *Bœtica anguſtifolia. Cluſ.* Narrow-leav'd *Spaniſh* Myrtle, *commonly call'd*, The Upright Myrtle.
9. Myrtus *balſamica, foliis mali granatæ. H. L.* The Pomegranate-leav'd Myrtle.
10. Myrtus *latifolia Bœtica ſecunda, vel foliis laurinis confertim naſcentibus. C. B. P.* The Orange-leav'd Myrtle, *vulgo*.
11. Myrtus *minor, foliis ex albo variegatis.* The ſtriped Thyme-leav'd Myrtle.
12. Myrtus *foliis odore nucis moſchatæ, cauliculis rubentibus,*

bus, foliis ex luteo variegatis. The ſtriped Nutmeg Myrtle, *vulgo.*

13. Myrtus *foliis mucronatis, ex albo & viridi variegatis, floſculis rubro candidis. Boerb. Ind.* The ſtriped Thyme-leav'd Myrtle, *vulgo.*

14. Myrtus *latifolia Romana, foliis ex luteo variegatis.* The broad-leav'd Myrtle, with ſtriped Leaves.

There are ſome other Varieties of theſe Plants which are preſerv'd in the Gardens of the Curious, but thoſe here mention'd are what I have obſerv'd in the Gardens near *London.*

Theſe Plants may be all propagated from Cuttings; the beſt Seaſon for which is in *July*, when you ſhould make Choice of ſome of the ſtraiteſt and moſt vigorous young Shoots, which ſhould be about ſix or eight Inches long, and the Leaves on the Lower Part muſt be ſtripp'd off about two Inches high, and the part twiſted which is to be plac'd in the Ground: Then having fill'd a Parcel of Pots (in Proportion to the Quantity of Cuttings deſign'd) with light rich Earth, you ſhould plant the Cuttings therein at about two Inches Diſtance from each other, obſerving to cloſe the Earth faſt about them, and give them ſome Water to ſettle it to the Cuttings; then place the Pots under a common Hot-bed Frame, plunging them either into ſome old Dung or Tanners-bark, which will prevent the Earth from drying too faſt; but you muſt carefully ſhade them with Mats in the Heat of the Day, and give 'em Air in proportion to the Warmth of the Seaſon, not forgetting to water them every two or three Days, as you ſhall find the Earth in the Pots require it: With this Management, in about a Month's time, the Cuttings will be rooted, and begin to ſhoot; when you muſt inure 'em to the open Air by degrees, into which they ſhould be remov'd towards the latter End of *Auguſt*, placing them in a Situation where they may be ſhelter'd from cold Winds, in which Place they may remain till *October*; when the Pots ſhould be remov'd into the Green-houſe, but ſhould be plac'd in the cooleſt Part thereof, that they may have Air given to them whenever the Weather is mild, for they require only to be protected from ſevere Cold, except the *Orange-leav'd* and the ſtrip'd *Nutmeg Myrtles*, which are ſomewhat tenderer than the reſt, and ſhould have a warmer Situation.

During the Winter-ſeaſon they muſt be frequently water'd, and if any decay'd Leaves appear they ſhould be conſtantly pick'd off, as alſo the Pots kept clear from Weeds, which if permitted to grow, will ſoon overſpread the young Plants and deſtroy them.

The *March* following theſe Plants ſhould be taken out of the Pots very carefully, preſerving a Ball of Earth to the Roots of each of them, and every one ſhould be placed into a ſeparate ſmall Pot fill'd with rich light Earth, obſerving to water them well to ſettle the Earth to their Roots, and place them in the ſhady Part of the Green-houſe until they have taken Root, after which they ſhould be inur'd to the Sun and Air; and in *May* they muſt be expos'd to the open Air, obſerving to place them near Hedges, where they may be defended from ſtrong Winds.

During the Summer-ſeaſon they will require to be plentifully water'd, eſpecially being in ſuch ſmall Pots, which in that Seaſon ſoon dries, therefore you ſhould obſerve to place them where they may have only the Morning-Sun, for when they are too much expos'd to the Sun in the Heat of the Day, the Moiſture contain'd in the Earth of thoſe ſmall Pots will ſoon be exhal'd, and the Plants greatly retarded in their Growth thereby.

In *Auguſt* following you ſhould examine your Pots, to ſee if the Roots of the Plants have not made Way out through the Hole in the Bottom of the Pots; which if you obſerve, you muſt then ſhift them into Pots a Size bigger, filling them up with the like rich Earth, and obſerve to trim the Roots which were matted to the Side of the Pots, as alſo to looſen the Earth from the Outſide of the Ball with your Hands, ſome of which ſhould be taken off, that the Roots may the eaſier find Paſſege into the freſh Earth; then you muſt water them well, and place the Pots in a Situation where they may be defended from ſtrong Winds: And at this time you may trim the Plants, in order to reduce them to a regular Figure; and if they are inclinable to make crooked Stems, you ſhould thruſt down a ſlender ſtrait Stick cloſe by them, to which their Stems ſhould be faſten'd, ſo as to bring 'em upright.

If Care be taken to train them thus while they are young, the Stems afterwards, when they have acquired Strength, will continue ſtrait without any Support, and their Branches may be prun'd, ſo as to form either Balls or Pyramids; which for ſuch Plants as are preſerv'd in the Green-houſe, and require to be kept in ſmall Compaſs, is the beſt Method to have them handſome: But then theſe ſheer'd Plants will not produce any Flowers; for which Reaſon that Sort with double Flowers ſhould not be clipp'd, becauſe the chief Beauty of that conſiſts in its Flowers: But it will be neceſſary to ſuffer a Plant or two of each Kind to grow rude, for the Uſe of their Branches in Noſegays, &c. for it will greatly deface thoſe which have been conſtantly ſheer'd to cut off their Branches.

As theſe Plants advance in Stature, ſo they ſhould annually be remov'd into larger Pots, according to the Size of their Roots, but you muſt be careful not to put them in Pots too large, which will cauſe them to ſhoot weak and ſtraggling, and many times proves the Deſtruction of them; therefore when they are taken out of the former Pots, the Earth about their Roots ſhould be pared off, and that withinſide the Ball muſt be gently looſen'd, that the Roots may not be too cloſely confin'd; and then place them into the ſame Pots again, provided they are not too ſmall, filling up the Sides and Bottom of them with freſh rich Earth, and giving them Plenty of Water to ſettle the Earth to their Roots, which ſhould be frequently repeated, for they require to be often water'd both in Winter and Summer; but in hot Weather they muſt have it in Plenty.

The beſt Seaſon for ſhifting theſe Plants, is either in *April* or *Auguſt*, for if it be done much ſooner in the Spring, the Plants are then in a ſlow growing State, and ſo not capable to ſtrike out freſh Roots again very ſoon: And if it be done later in Autumn, the cold Weather coming on will prevent their taking Root; nor is it adviſeable to do it in the great Heat of Summer, becauſe they will require to be very often water'd, and alſo to be plac'd in the Shade, otherwiſe they will be liable to miſcarry: And that being the Seaſon when theſe Plants ſhould be plac'd amongſt other Exoticks to adorn the ſeveral Parts of the Garden, theſe Plants being then remov'd, could not be expos'd until they have taken Root again, which at that time (if the Seaſon be hot and dry) will be three Weeks or a Month.

In *October*, when the Nights begin to have Froſts, you ſhould remove the Plants into the Green-houſe; but if the Weather proves favourables in *Autumn*, (as it often happens) they may remain abroad until the Beginning of *November*; for if they are carry'd into the Green-houſe too ſoon, and the Autumn ſhould prove warm, they will make freſh Shoots at that Seaſon, which will be weak, and often decay in Winter, if the Weather ſhould be ſevere, whereby they will be greatly defac'd; for which Reaſon they ſhould always be kept as long abroad as the Seaſon will permit, and remov'd out again in the Spring before they ſhoot out; and during the Winter-ſeaſon that they are in the Green-houſe, they ſhould have as much free Air as poſſible when the Weather is mild.

The two firſt mention'd Sorts I have ſeen planted abroad in warm Situations, and upon a dry Soil, where they have endured the Cold of Winters for ſeveral Years very well, with only being cover'd in very hard Froſts with two or three Mats, and the Surface of the Ground about their Roots cover'd with a little Mulch to prevent the Froſt from entering the Ground: But in *Cornwall* and *Devonſhire*, where the Winters are more favourable than in moſt other Parts of *England*, there are large Hedges of *Myrtle* which have been planted ſeveral Years, and are very thriving and vigorous, ſome of which are upward of ſix Feet high; and I believe if the Double-flowering Kind were planted abroad, it would endure the Cold as well as any of the other Sorts, it being a Native of the Southern Parts of *France*. This and the *Orange-leav'd* Kind, are the moſt difficult to take Root from Cuttings; but if they are planted toward the latter end of *July*, making Choice of only ſuch Shoots as are tender, and the Pots be plung'd into an old Bed of Tanners-bark which has loſt moſt of its Heat, and the Glaſſes ſhaded every Day, they will take Root extremely well, as I have more than once experienc'd. The *Orange-leav'd* Sort, and thoſe with variegated Leaves are ſomewhat tenderer than the ordinary Sorts, and ſhould be hous'd a little ſooner in Autumn, and plac'd farther from the Windows of the Green-houſe.

MYRTUS BRABANTICA. *Vide* Gale.

MYXA, The Sebeſten.

The *Characters* are;

It hath a Roſe-ſhaped Flower conſiſting of five Leaves. Theſe grow in Bunches. At the Bottom of the Flower-cup is the Ovary, which afterward becomes a plum-ſhap'd Fruit, including a Nut, which has ſometimes one, and at other times three Cells, in which is contain'd the Seed.

We have but one *Species* of this Plant in *Europe*, which is;

Myxa. *Dod. p.* 806. The Sebeſten Plum.

This Plant is very rare at preſent in *Europe*, being to be found in very few Gardens. It is propagated by Seeds, which do not ripen in *Europe* ; ſo the Seeds ſhould be obtained from the *Eaſt-Indies*, which is the natural Country of their Growth ; but as the Paſſage is long from thence to *Europe*, ſo the Seeds ſeldom come good to *England*. Therefore they ſhould be taken freſh from the Tree, and put into Tubs of Earth or Sand, and Care taken of them in their Paſſage, that the Salt-water do not come to them, nor Vermin deſtroy them. When they arrive, they ſhould be taken out of the Tub, and planted in ſmall Pots, filled with light rich Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving frequently to water the Earth, in order to forward the Vegetation of the Seed. When the Plants come up about two Inches high, they ſhould be each tranſplanted into a ſeparate ſmall Pot filled with light rich Earth, and then plunged into the Hot-bed again, obſerving to ſcreen them from the Sun until they have taken new Root; after which Time they muſt have a large Share of freſh Air in warm Weather, and ſhould be frequently refreſhed with Water. The Plants may remain in the Hot-bed till the Autumn, when they ſhould be removed into the Stove ; and the firſt Year, being young, they ſhould be kept pretty warm ; but as the Plants grow ſtronger, ſo they will bear to be uſed more hardily, tho' they ſhould always be placed in a Stove in Winter, otherwiſe they will not thrive in this Country.

The Fruit of this Tree was formerly uſed in Medicine, but of late Years they have been neglected, ſo that they are rarely brought into *England*.

N A

NAPELLUS. *Vide* Aconitum.

NAPUS ; The Navew *or* French Turnip.

The *Characters* are ;

It agrees in moſt reſpects with the Turnip, but hath a leſſer Root, and ſomewhat warmer to the Taſte.

The *Species* are ;

1. NAPUS *ſativa radice alba. C. B. P.* Garden Navew, with a white Root.
2. NAPUS *ſativa radice nigra. C. B. P.* Garden Navew, with a black Root.
3. NAPUS *ſylveſtris. C. B. P.* Wild Navew.

The two firſt Species of this Plant are cultivated in *France*, *Italy*, and *Germany*, in great Abundance ; in which Places they are much preferr'd to common *Turnips*, being accounted a more delicious Food ; but in *England* they have not yet ſo much obtain'd, being only cultivated by ſome curious Perſons, and are but rarely brought to the Markets.

Theſe Plants may be cultivated by ſowing their Seeds in *June*, *July*, and *Auguſt*, after the ſame manner as is practis'd for common *Turnips* ; and when the Plants are come up, they ſhould be hough'd in the like manner to deſtroy the Weeds, and cut up the Plants where they come up too thick, with this Difference only, *viz.* that theſe may be left cloſer together than common *Turnips*, for neither their Leaves nor Roots do grow near ſo large ; Theſe Plants being thus clear'd from Weeds, and cut up where they are too thick, will require no farther Care until they are fit for Uſe, which (if the Seaſon proves favourable) will be in about two Months after they are ſown, when they muſt be drawn up, and treated as common *Turnips*. The wild Sort is pretty common upon dry Banks in moſt Parts of *England*, where it flowers early in the Spring, but is never cultivated in Gardens ; but in the Iſle of *Ely* it is very much cultivated, it being the Cole Seed from which they draw an Oil : The Seeds of this Kind are us'd in Medicine, and by moſt preferr'd to thoſe of the Garden Sort.

NARCISSO-LEUCOJUM ; [This Plant is ſo call'd becauſe it reſembles both the *Narciſſus* and *Leucojum*] The Snow-drop, *vulgo*.

The *Characters* are ;

The Flower is for the moſt part compos'd of ſix Leaves in form of a Lily, *which are ſometimes equal, and ſometimes unequal and pendulous ; the Empalement becomes a roundiſh Fruit, which is divided into three Cells, and full of roundiſh Seeds : To which may be added, It hath a bulbous Root.*

The *Species* are ;

1. NARCISSO-LEUCOJUM *trifolium minus. Tourn.* Leſſer Bulbous-violet *or* Snow drop.
2. NARCISSO-LEUCOJUM *vulgare. Tourn.* Common Bulbous-violet *or* Snow-drop.
3. NARISSO-LEUCOJUM *trifolium minus, flore pleno. Boerh. Ind.* The double Snow-drop.
4. NARCISSO-LEUCOJUM *trifolium majus. Tourn.* Greater Snow-drop *or* Bulbous-violet.
5. NARCISSO-LEUCOJUM *altiſſimum, flore parvo albo, apicibus viridibus. Boerh. Ind.* The talleſt Snow-drop, with ſmall white Flowers tipp'd with Green.

The firſt of theſe Plants is very common in moſt *Engliſh* Gardens, where it is preſerv'd for its early flowering, which is generally in *January*, when they often appear, tho' the Ground at that Time be cover'd with Snow, and is one of the firſt Uſherers in of the Spring.

This Plant is very eaſily propagated from Off-ſets, which the Roots ſend forth in great Plenty, (eſpecially if they are permitted to remain undiſturb'd for two or three Years) in which Time, from a ſingle Bulb, there will often be ten or twelve flowering Roots, and as many more ſmall Off-ſets.

The beſt Seaſon for tranſplanting the Roots is in *May*, after their Leaves are decay'd, when they muſt be taken up ; and after being dry'd in a ſhady Place, they may be kept out of the Ground until *September* before they need be planted again ; when they ſhould be planted about two Inches deep, and pretty cloſe together, otherwiſe their Flowers being ſmall, will make but a poor Appearance.

They will thrive in almoſt any Soil or Situation, but are commonly planted near Hedges, and by the Sides of large Walks ; where being permitted to remain two or three Years unremov'd, till they have increas'd, and become large Bunches, they make a very good Appearance before any other Flowers come up.

The Double Sort is preferr'd to the Single, for the Largeneſs and Fairneſs of its double Flowers. This may be propagated as the laſt, but does not multiply quite ſo faſt, nor do the Flowers appear ſo ſoon in the Spring, but they are of longer Duration.

The Great *Snow-drop* is pretty rare in *England*, and only to be found in ſome curious Gardens. This produces much larger Flowers than the common Sort, and generally riſes eight or ten Inches high. It flowers toward the Latter-end of *February* or the Beginning of *March*, and continues a long Time in Beauty. This is alſo propagated by Off-ſets as the former, but does not increaſe very faſt : It requires a middling Soil which is freſh, but ſeldom thrives well in very rich Ground, and ſhould be planted to an Eaſt or South-Eaſt Aſpect, where it may have the Morning Sun ; in which Situation it will thrive better than if expos'd to a greater Heat.

The talleſt *Snow-drop* is a very hardy Plant, and increaſes pretty faſt by Off-ſets, ſo that it is much commoner than the laſt. This flowers in *April* and *May*, and generally riſes two Feet high. The Bulbs of this Kind are very large, and do greatly reſemble thoſe of the *Narciſſus*, and the Leaves are very broad, but the Flowers are ſmall, and ſeldom more than two or three produc'd upon each Stalk. Theſe make a pretty Variety when intermix'd with other bulbous-rooted Flowers.

All theſe Sorts may be tranſplanted when their Leaves are decay'd, before they ſtrike out freſh Fibres, after which it will be too late to remove them : Their Roots may be kept out of the Ground two or three Months, if preſerv'd in a dry Place, and may be planted in almoſt any Soil, but they thrive beſt in a freſh light ſandy Earth.

NARCISSUS ; [takes its Name of ναρκὸς, or ναρκὴ, a *Torpidneſs* or *Deep-ſleep*, becauſe the Smell of this Flower is ſaid to cauſe a Heavineſs of the Head, and a Stupidity. *Plutarch* tells us, This Plant was ſacred to the infernal Gods. The Poets tell us, that *Narciſſus* was the Son of *Cephiſus* and the Nymph *Lyriope*, a Youth of ſuch excellent Beauty, that once upon a Time coming to a Fountain to drink, and ſeeing his beauteous Image in the Water, he grew ſo enamour'd with it, that he pin'd away with Deſire, and was transform'd into a Flower of his Name.] The Daffodil.

The *Characters* are ;

It hath a Lily *Flower, conſiſting of one Leaf, which is* Bell-*ſhap'd, and cut into ſix Segments, which incircle its* Middle lik *a* Crown ; *but the Empalement, which commonly riſes out of* *membranous* Vagina, *turns to an oblong or roundiſh Fruit,* whic *is triangular, and gapes in three Parts, is divided into three Cells, and full of roundiſh Seeds.*

The *Species* are;

1. Narcissus *ſylveſtris pallidus, calyce luteo. C. B. P.* Wild *Engliſh* Daffodil.

2. Narcissus *medio-luteus vulgaris. Park.* Common pale Daffodil, or Primroſe Peerleſs.

3. Narcissus *major totus luteus, calyce prælongo. C. B. P.* Great yellow *Spaniſh* Daffodil, with a long Cup.

4. Narcissus *latifolius omnium maximus, amplo calyce flavo five nonpareille. Park. Par.* The Great Nonpareil or Nonſuch Daffodil.

5. Narcissus *parvus totus luteus. C. B. P.* Small yellow *Spaniſh* Daffodil.

6. Narcissus *luteus, florum petalis reflexis. C. B. P.* Yellow Daffodil, with the Leaves of its Flowers turning back.

7. Narcissus *multiplex totus flavus. C. B. P.* Common yellow Daffodil, with a double Flower.

8. Narcissus *incomparabilis, flore pleno, partim flavo, partim croceo. H. R. Par.* The incomparable double Daffodil, with the Flower-leaves partly yellow, and partly of a Saffron Colour.

9. Narcissus *latifolius, flore pleniſſimo, petalis majoribus candidis, minoribus aureis interpolatis. Boerh. Ind.* Nonſuch Daffodil, with a very double Flower, whoſe larger Leaves are white, but the leſſer Leaves (which are intermix'd) of a Gold Colour.

10. Narcissus *latifolius, flore pleniſſimo, petalis majoribus pallidis, minoribus flavis interpolatis. Boerh. Ind.* Nonſuch Daffodil, with a very double Flower, whoſe larger Leaves are of a pale Colour, which are intermix'd with ſmaller Leaves of a yellow Colour.

11. Narcissus *latifolius, flore pleniſſimo, petalis partim flavis, partim viridibus interpolatis.* Broad-leav'd Daffodil, with a very double Flower, whoſe Leaves are ſome yellow, and others green, intermix'd, *commonly call'd* Tradeſcant's Daffodil.

12. Narcissus *Anglicus, flore pleno.* The double *Engliſh* Daffodil.

13. Narcissus *latifolius, ſulphureus vel albus, brevi calyce. C. B. P.* Broad-leav'd Daffodil, with a Brimſtone-colour'd Flower, having a ſhort Cup.

14. Narcissus *latifolius ſulphureus, calycis brevis aurei ora fimbriata. Boerh. Ind. Alt.* Broad-leav'd Brimſtone-colour'd Daffodil, with a ſhort Gold-colour'd Cup, fring'd about the Edge.

15. Narcissus *Illyricus liliaceus. C. B. P.* The Sea Daffodil, or Narciſſus tertius Matthioli.

16. Narcissus *maximus pallidus, foliis incanis. C. B. P.* Greater pale-colour'd Daffodil.

17. Narcissus *albus multiplex. Park. Par.* The double white Daffodil, or Narciſſus.

18. Narcissus *albus, circulo croceo. C. B. P.* The white Daffodil, with the Rim of the Cup of a Saffron Colour.

19. Narcissus *Narbonenſis, ſive medio luteus, ſerotinus major. Park. Par.* The Great late-flowering *French* Daffodil.

20. Narcissus *Orientalis albus, calyce luteo, campanulæ ſimilis maximus. C. B. P.* The Boſſelman's Narciſſus, *vulgo.*

21. Narcissus *Orientalis albus, calyce luteo, medius. C. B. P.* Oriental white Daffodil, with a yellow Cup.

22. Narcissus *luteus polyanthos Luſitanicus. C. B. P.* Yellow Portugal Daffodil, with many Flowers.

23. Narcissus *Orientalis albus minor, calyce ſulphureo pallido amplo. Boerh. Ind.* Leſſer white Oriental many-flower'd Daffodil, with an ample pale Brimſtone-colour'd Cup.

24. Narcissus *pallidus medio aureus. C. B. P.* Pale Daffodil, with a Golden Cup, *commonly call'd* Le Soleil D'Or.

25. Narcissus *Orientalis albus, calyce luteo, minor. C. B. P.* Leſſer white Oriental Daffodil, with a yellow Cup.

26. Narcissus *Orientalis albus, calyce ſtellato. C. B. P.* Oriental white Daffodil, with a ſtarry Cup.

27. Narcissus *Orientalis lacteus maximus, calyce pallido amplo. Boerh. Ind.* Largeſt Oriental white Daffodil, with an ample pale Cup, *commonly call'd* The Czar of Muſcovy.

28. Narcissus *Orientalis maximus lacteus, calyce pallido parvo. Boerh. Ind.* Greateſt white Oriental Narciſſus, with a ſmall pale-colour'd Cup.

29. Narcissus *Orientalis major polyanthos totus albus. H. Eyſt.* Great Oriental Narciſſus, with many white Flowers upon a Stalk.

30. Narcissus *Orientalis medius polianthos totus albus. H. Eyſt.* Middle Oriental Narciſſus, with many white Flowers upon a Stalk.

31. Narcissus *Orientalis minor polyanthos totus albus. H. Eyſt.* Leſſer Oriental Narciſſus, with many white Flowers upon a Stalk.

32. Narcissus *juncifolius, oblongo calice, luteus major. C. B. P.* Single yellow Jonquil, with a large oblong Cup.

33. Narcissus *juncifolius luteus minor. C. B. P.* Leſſer ſingle yellow Jonquil.

34. Narcissus *juncifolius, flore pleno. Cluſ. Cur. Poſt.* Double yellow Jonquil.

35. Narcissus *juncifolius, petalis anguſtiſſimis, calyce maximo tubam referente. Boerh. Ind.* Ruſh-leaf'd Daffodil, with very narrow Petals, and a large tubulous Cup, *commonly call'd* the Hoop-Petticoat.

36. Narcissus *juncifolius, flore pallidiore, calyce flavo. C. B. P.* Ruſh-leaf'd Daffodil, with a paler Flower, and a yellow Cup.

37. Narcissus *medio-purpureus. Hort. Eyſt.* Single Daffodil, with a white Flower, and a purple Middle.

38. Narcissus *Conſtantinopolitanus polyanthos major, melino pleno flore. H. R. Par.* Greater many-flowered Daffodil of *Conſtantinople*, with double yellow Flowers.

39. Narcissus *Cyprius luteus polyanthos, flore pleno. Lob. Adv.* Many-flowered Daffodil of *Cyprus*, with double yellow Flowers, commonly called the *Cyprus Narciſſus.*

40. Narcissus *Orientalis polyanthos, pleno flore, petalis exterioribus albis, interioribus luteis, odoratiſſimus. Cleric.* Sweet-ſcented Eaſtern Daffodil, with many double Flowers, whoſe outer Leaves are white, and the inner Leaves yellow.

41. Narcissus *niveus, calyce flavo, odoris fragrantiſſimi. C. B. P.* Snow-white Daffodil, with a yellow Cup, and of a fragrant Scent.

42. Narcissus *Orientalis polyanthos, floribus odoris fragrantiſſimi. Cler.* Many-flowered Eaſtern Daffodil, with ſnow-white Flowers, and a very fragrant Odour.

43. Narcissus *Orientalis polyanthos major, flore flaveſcente ſtellato.* Greater many-flowered Eaſtern Daffodil, with a yellowiſh ſtarry Flower.

44. Narcissus *Orientalis polyanthos major, flore aureo, calyce flaveſcente ſtellato.* Greater many-flowered Eaſtern Daffodil, with a golden Flower, having a pale yellow ſtarry Cup.

45. Narcissus *albus, flore minore, jaſmini odore. C. B. P.* White Daffodil, with a ſmaller Flower, ſmelling like Jaſmine.

46. Narcissus *Orientalis polyanthos albus odoratus, calyce ſtellato.* Eaſtern many-flowered Daffodil, with white ſweet-ſcented Flowers, having a ſtarry Cup.

47. Narcissus *Americanus anguſtifolius, croci flore. Houſt.* Narrow-leaved *American* Daffodil, with a ſaffron-coloured Flower.

There are ſeveral Varieties of theſe Flowers, which are annually brought over from *Holland* and *Flanders*, where the Gardeners are very induſtrious in raiſing theſe and moſt other Bulbous-rooted Flowers from Seeds, whereby they continually procure ſome new Varieties, which recompenſes them for their Trouble and Expence: But in *England* there are very few Perſons who have Patience to propagate any of theſe Flowers that Way, it being commonly five Years before they can expect to ſee the Fruits of their Labour: However, after the firſt five Years are paſt, if there be Seeds ſown every Year, there will be annually a Succeſſion of Flowers to ſhew themſelves; ſo that there will be a continual Expectation; which will take off the Tediousneſs which, during the firſt five Years, might be very troubleſome to ſome Perſons; and the annual Production of new Flowers correſponding to the annual Sowing, it will be as if the Product aroſe ſoon after.

The not practiſing this Method, has occaſion'd our ſending Abroad annually for great Quantities of Flower-roots, which have been kept up to a great Price, on account of the great Demand for 'em in *England*; whereas if we were as induſtrious to propagate them as our Neighbours, we might ſoon vie with them, if not out-do 'em, in moſt Sorts of Flowers; as may be eaſily ſeen, by the vaſt Variety of *Carnations, Auricula's, Ranuncula's*, &c. which are what have been produc'd from Seeds in *England*, and do exceed every thing of thoſe Kinds in any Part of *Europe.*

I ſhall therefore firſt lay down the Method of propagating theſe Flowers from Seeds; and afterwards proceed to the neceſſary Directions for increaſing them from Off-ſets; with the manner of treating the Roots, to produce ſtrong Flowers.

You muſt be very careful, in ſaving your Seeds, to gather none but from ſuch Flowers as have good Properties, and particularly from ſuch only as have many Flowers upon a Stalk, that flower tall, and have beautiful Cups to their Flowers; from ſuch you may expect to have good Flowers produc'd: But if you ſow ordinary Seed, it is only putting yourſelf to Trouble and Expence to no Purpoſe; ſince from ſuch Seeds there can be no Hopes of procuring any valuable Flowers.

Having provided yourſelf with good Seeds, you muſt procure either ſome ſhallow Caſes or flat Pans made on Purpoſe for the raiſing of Seedlings, which ſhould have Holes in their Bottoms, to let the Moiſture paſs off; theſe muſt be fill'd with freſh light ſandy Earth about the Beginning of *Auguſt*, (this being the beſt Seaſon for ſowing the Seeds of moſt Bulbous-rooted Flowers) which much be levell'd very even; then ſow the Seeds thereon pretty thick, covering them over with fine ſifted light Earth about half an Inch thick, and place the Caſes or Pans in a Situation where they may have only the Morning Sun till about ten o'Clock, where they ſhould remain until the Beginning of *October*, when they muſt be removed into a warmer Situation, placing 'em upon Bricks, that the Air may freely paſs under the Caſes, which will preſerve them from being too moiſt.

They ſhould alſo be expos'd to the full Sun, but ſcreen'd from the cold North and Eaſt Winds, where they may remain until the Beginning of *April*, by which Time the Plants will be up, when you muſt carefully clear 'em from Weeds; and if the Seaſon ſhould prove dry, they muſt be frequently water'd: The Caſes ſhould alſo now be remov'd into their former ſhady Poſition; for the Heat of the Noon-day Sun will be too great for the young Plants.

The Latter-end of *June*, when the Leaves of the Plants are decay'd, you ſhould take off the upper Surface of the Earth in the Caſes, (which by that Time will have contracted a Moſſineſs, and, if ſuffer'd to remain, will greatly injure the young Roots), obſerving not to take it ſo deep as to touch the Roots; then ſift ſome freſh light Earth over the Surface about half an Inch thick, which will greatly ſtrengthen the Roots: The ſame ſhould alſo be repeated in *October*, when the Caſes are mov'd into the Sun.

During the Summer Seaſon, if the Weather ſhould prove very wet, and the Earth in the Caſes appear very moiſt, you muſt remove 'em into the Sun till the Earth be dry again; for if the Roots receive much Wet during the Time they are unactive, it very often rots them; therefore you muſt never give 'em any Water after their Leaves are decay'd, but only place 'em in the Shade, (as was before directed).

Thus you ſhould manage them the two firſt Seaſons, till their Leaves are decay'd the ſecond Summer after ſowing, when you ſhould carefully take up the Roots; which may be done by ſifting the Earth in the Caſes with a fine Sieve, whereby the Roots will be eaſily ſeparated from the Earth; then having prepared a Bed or two of good freſh light Earth, in proportion to the Quantity of your Roots, you ſhould plant 'em therein at about three Inches Diſtance every Way, and about three Inches deep in the Ground.

Theſe Beds ſhould be rais'd above the Level of the Ground, in proportion to the Moiſture of the Soil, which if dry, three Inches will be enough; but if it be wet, they muſt be rais'd ſix or eight Inches high, and laid a little rounding to ſhoot off the Wet.

If theſe Beds are made in *July*, which is the beſt Time to tranſplant the Roots, the Weeds will ſoon after appear very thick; therefore you ſhould gently hough the Surface of the Ground, to deſtroy 'em; being very careful not to cut ſo deep as to touch any of the Roots; and this ſhould be repeated as often as may be found neceſſary by the Growth of the Weeds, obſerving always to do it in dry Weather, that they may be effectually deſtroy'd: And toward the Latter-end of *October*, after having intirely clear'd the Beds from Weeds, you ſhould ſift a little rich light Earth over them about an Inch thick, the Goodneſs of which will be waſh'd down to the Roots by the Winter's Rain, which will greatly encourage their Shooting in the Spring.

If the Cold ſhould be very ſevere in Winter, you ſhould cover the Beds with Peaſe-haulm, or ſome ſuch light Covering, to prevent the Froſt from penetrating the Ground to the Roots, which might greatly injure them while they are ſo young.

In the Spring, when the Plants begin to appear above Ground, you muſt gently ſtir the Surface of the Ground, clearing it from Weeds, *&c.* in doing of which, you ſhould be very careful not to injure the Plants: and if the Seaſon ſhould prove dry, you ſhould now-and-then gently refreſh 'em with Water, which will ſtrengthen the Roots.

When their Leaves are decay'd, you ſhould clear the Beds from Weeds, and ſift a little Earth over 'em, (as was before directed); which muſt alſo be repeated in *October*, in like manner; and ſo every Year continu'd till the Roots flower, when you ſhould mark all ſuch as promiſe well, which ſhould be taken up as ſoon as their Leaves decay, and planted at a greater Diſtance in new-prepared Beds: But thoſe which do not flower, or thoſe you do not greatly eſteem, ſhould be permitted to remain in the ſame Bed; therefore, in taking up thoſe Roots which you mark'd, you muſt be careful not to diſturb the Roots of thoſe left, and alſo to level the Earth again, and ſift ſome freſh Earth over the Beds (as before), to encourage the Roots; for it often happens, in the Seedlings of theſe Flowers, that at their firſt Time of Blowing, their Flowers do ſeldom appear half ſo beautiful as they do the ſecond or third Year; for which Reaſon none of them ſhould be rejected until they have flower'd two or three times, that ſo you may be aſſured of their Worth.

Thus having laid down Directions for the Sowing and Managing theſe Roots, until they are ſtrong enough to flower; I ſhall proceed to give ſome Inſtructions for Planting and Managing the Roots afterwards, ſo as to cauſe 'em to produce large fair Flowers.

All the Sorts of *Narciſſus* which produce many Flowers upon a Stalk, ſhould have a Situation defended from Winds, otherwiſe they'll be ſubject to be brought down while in Flower; for notwithſtanding their Stalks are generally pretty ſtrong, yet the Number of Flowers upon each, renders their Heads weighty, eſpecially after Rain, which lodges in the Flowers, and, if ſucceeded by ſtrong Winds, very often deſtroys their Beauty, if they are expos'd thereto; ſo that a Border under a Hedge, which is open to the South-Eaſt, is preferable to any other Poſition for theſe Flowers.

The Morning Sun riſing upon them will dry off the Moiſture which had lodged upon them the preceding Night, and cauſe 'em to expand fairer than when they are planted in a ſhady Situation; and if they are too much expos'd to the Afternoon Sun, they will be hurry'd out of their Beauty very ſoon; and the ſtrong Winds uſually coming from the Weſt and South-Weſt Points, they will be expos'd to the Fury of them, which frequently is very injurious to them. But you ſhould not plant them under a Wall, or any other cloſe Fence; for that will reflect the Heat too greatly upon the Flowers, and alſo draw them up with weak Stems, ſo that they will not flower ſo ſtrong, nor continue ſo long in Beauty.

Having made choice of a proper Situation, you muſt then proceed to prepare the Earth neceſſary to plant them in; for if the natural Soil of the Place be very ſtrong, or poor, it will be proper to make the Border of new Earth, removing the former Soil away about a Foot deep. The beſt Earth for theſe Flowers is a freſh light hazle Loam, mix'd up with a little very rotten Dung, or tan; this ſhould be well mix'd together, and often turn'd over, in order to ſweeten it: Then having remov'd away the old Earth at leaſt a Foot deep, you ſhould put a Laying of rotten Dung or Tan in the Bottom about two Inches thick, upon which you muſt lay ſome of the prepared Earth about four Inches thick, making it exactly level; then having mark'd out by Line the exact Diſtances at which the Roots are to be planted (which ſhould not be leſs than four or five Inches ſquare) you muſt place the Roots accordingly, obſerving to ſet them upright; then you muſt cover them over with the before-mention'd Earth about ſix Inches deep, being very careful, in doing of it, not to diſplace the Roots: When this is done, you muſt rake the Surface of the Border even, and make up the Side ſtrait, which will appear handſome.

The beſt Time for planting theſe Roots is in *Auguſt*; for if they are kept too long out of the Ground, it will cauſe their Flowers to be very weak. You ſhould alſo obſerve the Nature of the Soil where they are planted, and, whether the Situation be wet or dry, according to which you ſhould adapt the freſh Earth, and order the Beds; for if the Soil be very ſtrong, and the Situation moiſt, you ſhould then make choice of a light Earth, and raiſe the Beds ſix or eight Inches above the Level of the Ground, otherwiſe the Roots will be in danger of periſhing by too much Wet: But if the Situation be dry, and the Soil naturally light, you ſhould then allow the Earth to be a little ſtronger: And the Beds ſhould not be rais'd above three Inches high; for if they are made too high, the Roots will ſuffer very much, if the Spring ſhould prove dry, nor would the Flowers be near ſo fair.

Toward the Middle of *October*, if the Weeds have grown upon the Beds, you ſhould, in a dry Day, gently hough the Surface of the Ground, to deſtroy them, obſerving to rake it over ſmooth again: After which, they will require no farther Care till the Spring, when their Leaves will appear above Ground, at which Time you ſhould gently ſtir the Surface of the Earth, with a ſmall Trowel, being very careful not to injure the Leaves of the Plants, and rake it ſmooth with your Hands, clearing off all Weeds, *&c.* which, if ſuffer'd to remain at that Seaſon, will ſoon grow ſo faſt, as to appear very unſightly, and will exhauſt the Nouriſhment from the Earth.

With this Management theſe Roots will flower very ſtrong, ſome of which will appear in *March*, and the others in *April*; which, if ſuffer'd to remain, will continue in Beauty a full Month, and are at that Seaſon very great Ornaments to a Flower-Garden.

After the Flowers are paſt, and the Leaves decay'd, you ſhould ſtir the Surface of the Ground, to prevent the Weeds from growing; and if at the ſame time you lay a little very rotten Dung over the Surface of the Beds, the Rain will waſh down the Salts thereof, which will greatly encourage the Roots the ſucceeding Year.

During the Summer Seaſon they will require no farther Care, but to keep them clear from Weeds till *October*, when the Surface of the Beds ſhould be again ſtirr'd, raking off all Weeds, *&c.* and laying ſome good freſh Earth over the Beds about an Inch deep, which will make good the Loſs ſuſtain'd by Weeding, *&c.* and in Spring you muſt manage as was before directed for the preceding Year.

Theſe Roots ſhould not be tranſplanted oftener than every third Year; becauſe the firſt Year after removing they never flower ſo ſtrong as they do the ſecond and third; nor will the Roots increaſe ſo faſt when they are often tranſplanted; but if you let them remain longer than three Years unremov'd, the Number of Off-ſets, which by that Time will be produced, will weaken the large Bulbs, and cauſe them to produce very weak Flowers; therefore, at the Time of tranſplanting them, all the ſmall Off-ſets ſhould be taken off, and planted in a Nurſery-bed by themſelves, but the large Bulbs may be planted again for Flowering. If you plant them in the ſame Bed where they grew before, you muſt take out all the Earth a Foot deep, and fill it up again with freſh, in the manner before directed, which will be equal to removing them into another Place: This is the conſtant Practice of the Gardeners in *Holland*, who have but little Room to change their Roots; therefore they every Year remove the Earth of their Beds, and put in freſh, ſo that the ſame Place is conſtantly occupy'd by the like Flowers.

The common Sort of *Daffodil* are generally planted in large Borders of the Pleaſure-Garden, where being intermix'd with other Bulbous rooted Flowers, they afford an agreeable Variety in their Seaſons of Flowering: Theſe Roots are very hardy, and will thrive in almoſt any Soil or Situation, which renders 'em very proper for Rural Gardens, where being planted under the Shade of Trees, they will endure ſeveral Years without tranſplanting, and produce annually, in the Spring, great Quantities of Flowers, which afford an agreeable Proſpect.

The *Jonquils* ſhould be planted in Beds, or Borders, ſeparate from other Roots; becauſe theſe require to be tranſplanted at leaſt every other Year, otherwiſe their Roots are apt to grow long and ſlender, and ſeldom flower well after; which is alſo the Caſe, if they are continued many Years in the ſame Soil; wherefore the Roots ſhould be often remov'd from one Part of the Garden to another, or at leaſt the Earth ſhould be often renew'd, which is the moſt probable Method to preſerve theſe Flowers in Perfection.

The Soil in which theſe Flowers ſucceed beſt, is a Hazle Loam, neither too light, nor over-ſtiff; it muſt be freſh, and free from Roots of Trees, or noxious Weeds; but ſhould not be dung'd; for 'tis very remarkable, that where the Ground is made rich, they ſeldom continue good very long, but are ſubject to ſhoot downwards, and form long ſlender Roots.

Theſe Flowers are greatly eſteem'd by many People for their ſtrong ſweet Scent, tho' there be very few Ladies that can bear the Smell of them; ſo powerful is it, that, many times, it overcomes their Spirits, eſpecially if confined in a Room; for which Reaſon they ſhould never be planted too cloſe to an Habitation, leſt they become offenſive; nor ſhould the Flowers be placed in ſuch Rooms where Company is entertain'd.

The thirty-ſeventh Sort is pretty common in many of the Gardens near *London*: this produces only one ſingle white Flower on the Top of the Stalk, which turns on one Side, and has a purple Rim to the Cup in the Middle: it flowers the latter End of *April*, and the Beginning of *May*, and is very hardy.

The other Sorts have been lately introduced into the *Engliſh* Gardens, ſo are not at preſent very common; but as theſe are all of them very hardy Plants, and multiply pretty faſt by Off-ſets, ſo in few Years they will be in as great Plenty as any of the other Kinds.

The thirty-eighth, thirty-ninth, fortieth, forty-firſt, forty-ſecond and forty-fifth Sorts, are extremely worth cultivating in every good Garden, for the ſake of their beautiful ſweet-ſmelling Flowers, which continue from the Middle of *March* to the End of *April*, unleſs the Seaſon proves very hot. The forty-fifth Sort produces often twenty Flowers on each Stalk, which are of a ſnow-white Colour, and ſmell exceedingly ſweet.

Theſe Sorts may be propagated after the Manner as hath been above directed.

The forty-ſeventh Sort was diſcovered by the late Dr. *William Houſtoun* at *La Vera Cruz*, where it grew in great Plenty. This hath Leaves like thoſe of the *Jonquil*, and there is but one Flower produced on each Stalk. It is propagated by Off-ſets from the Roots, in the ſame Manner as the common *Narciſſus*, but is very tender; ſo muſt be preſerved in the Bark-ſtove, and treated after the ſame Manner as the tender Kinds of *Lilio-narciſſus*, otherwiſe they will not thrive in this Country.

NASTURTIUM: This ſome derive of *Naſi Tormentum*, i. e. *Torment of the Noſe*; becauſe it has ſuch an Acrimony, that the Smell of the Seed bruiſed will provoke Sneezing] Creſs.

The *Characters* are;

The Flower conſiſts of four Leaves, which are placed in form of a Croſs; the Pointal, which riſes from the Centre of the Flower-cup, becomes a roundiſh ſmooth Fruit, which is divided into two Cells, by the intermediate Partition, obliquely placed, with reſpect to the Valves, and furniſh'd with Seeds, which are generally ſmooth: To which may be added, The Leaves are cut into many Parts, by which Creſs *is diſtinguiſh'd from* Thlaſpi, *or* Treacle-Muſtard.

The *Species* are;

1. NASTURTIUM *hortenſe vulgatum.* C. B. P. Common Garden-Creſs.
2. NASTURTIUM *hortenſe criſpum.* C. B. P. Curled Garden-Creſs.
3. NASTURTIUM *hortenſe latifolium.* C. B. P. Broad-leav'd Garden-Creſs.
4. NASTURTIUM *ſylveſtre, capſulis criſtatis.* *Tourn.* Swine's-Creſs, *or* Warted Bucks-horn.

The firſt Sort is commonly cultivated in Gardens as a Sallet-herb, and is chiefly eſteem'd in the Winter and Spring, it being one of the warm Kind. During the Winter Seaſon, it muſt be ſown upon a gentle Hot-bed, and cover'd with either Mats or Glaſſes, to preſerve it from great Rains or Froſt, both of which are equally deſtructive at that Seaſon: In the Spring it may be ſown in warm Borders, where, if it be defended from cold Winds, it will thrive very well: but if you would continue it in Summer, you muſt ſow it upon ſhady Borders, and repeat ſowing every Week, otherwiſe it will be too large for Uſe; for at that Seaſon it grows very faſt.

The *Broad-leav'd* and *Curled* Sorts are preſerv'd in ſome Gardens for Curioſity Sake, and to garniſh Diſhes, but the common Sort is equally as good for Uſe. Theſe ſhould be ſown ſomewhat thinner than the common Sort, and when the Plants come up, they ſhould be drawn out, ſo as to leave the remaining ones half an Inch aſunder, whereby they will have Room to expand their Leaves, in which their Difference from the common Sort conſiſts.

In order to preſerve theſe Varieties diſtinct, you muſt carefully ſeparate all ſuch Plants as appear inclin'd to degenerate from their Kinds, leaving only ſuch of the broad-leav'd Kind as have very fair broad Leaves; and ſo of the curl'd Sort, only ſuch as have their Leaves very much curl'd; being very careful not to intermix 'em together. When the Seeds are ripe, the Plants ſhould be drawn up, and ſpread upon a Cloth two or three Days to dry, after which the Seeds ſhould be beaten out, and preſerved in a dry Place for Uſe.

NASTURTIUM INDICUM. *Vide* Acriviola.

NATURAL; is belonging to, or proceding from *Nature*.

NATURAL FACULTY; is that *Faculty* or Action whereby Bodies are increaſed, nouriſhed, or preſerved.

NATURE; is a Term variouſly uſed, and Mr. *Boyle*, in a Treatiſe of *The vulgarly receiv'd Notion of Nature*, gives us eight principal ones.

1. *Nature* is uſed for the Syſtem of the World, the Machine of the Univerſe, or the Aſſemblage of all created Beings.

In this Senſe we ſay, the *Author of Nature*, meaning *God*; and ſpeaking of the *Sun*, call him the *Father of Nature*, becauſe he warms the Earth, and makes it fruitful; and the *Eye of Nature*, becauſe he illuminates the Univerſe; and of a Phœnix, an Unicorn, a Griffin, a Satyr, that there are no ſuch Things in *Nature*.

2. *Nature*, in a more confined Senſe, comprehends the ſeveral Kinds of Beings, created and uncreated; corporeal and ſpiritual; thus we ſay, human *Nature*, *i. e.* all Men who poſſeſs the ſame rational Souls; angelical *Nature*; divine *Nature*.

3. *Nature*, in a ſtill more reſtrain'd Senſe, is uſed for the Eſſence of a Thing, or that Attribute that makes a Thing what it is, as 'tis the *Nature* of the Soul to think.

4. *Nature* is particularly uſed for the eſtabliſh'd Order and Courſe of material Things, the Series of the Second Cauſes or the Laws that God has impos'd on the Motions impreſs'd by him. In this Senſe we ſay, The Day and Night, by *Nature*, ſucceed one another; Phyſick is the Study of *Nature*; Reſpiration is by *Nature* neceſſary to Life.

Again, in this Senſe we ſay, Miracles are Effects above Powers of *Nature*; and that Art exceeds *Nature*, by means of Machines and moving Powers which produce Effects which go beyond what we ſee in the common Courſe of Things.

5. *Nature* is alſo uſed to ſignify an Aggregate of Powers, which belong to any Body, eſpecially a living one. Thus we ſay, *Nature* is ſtrong, *Nature* is weak, *Nature* is ſpent, *&c.*

6. *Nature* is alſo more ſtrictly uſed for the Action of Providence, the Principle of all Things, or that ſpiritual Being which is diffus'd throughout the Creation, and moves and acts in all Bodies, and gives them certain Properties, and procures certain Effects. In this Senſe, *Nature* ſignifies the Qualities or Virtues that God has given to his Creatures, Animal, Vegetable, *&c.*

In ſpeaking of the Action of *Nature*, no more is to be underſtood, but that *Bodies act on one another*, in a Manner, *agreeable to the general Laws of Motion which the Creator has eſtabliſhed.*

Mr. *Boyle* alſo propoſes a Notion of *Nature*, as more fit than any yet given, to paſs for the principal one of *Nature*; with regard to which, many Axioms and Expreſſions relating to the Word *Nature*, may be conveniently underſtood; and in order to this, he diſtinguiſhes between *general* and *particular Nature.*

General Nature he defines the Aggregate of the Bodies that make up the World, conſider'd as a Principle, by Virtue whereof, they act and ſuffer according to the Laws of Motion, preſcrib'd by the Order of Things.

Particular Nature of any ſubordinate or individual, conſiſts in the *general Nature*, apply'd to a diſtinct Portion of the Univerſe. Or, it is a Convention of the Mechanical Properties, (as Magnitude, Figure, Order, Situation, and Local Motion) of Parts convenient and ſufficient to conſtitute, or intitle to its particular Species or Denominations, the particular Body they make up; the Concourſe of all theſe being conſider'd, as the Principle of Motion, Reſt, *&c.*

The *Laws of Nature* are Axioms or General Laws and Rules of Motion and Reſt, obſerv'd by natural Bodies in their Actions one on another; and in all the Changes which befal them in their *natural* State.

The Laws of *Nature* and of Motion are in Effect the ſame: Cuſtom, indeed, has made ſome Difference, and we find Authors call the particular Caſes of Motion, *Laws of Motion*; the more general or catholick ones, and thoſe from which, as from Axioms, the others are deduc'd, they call *Laws of Nature*.

Of theſe Sir *Iſaac Newton* has eſtabliſh three *Laws of Nature:*

1. Every Body perſeveres in the ſame State, either of Reſt, or Uniform Motion; except ſo far as it is forced to change that State by ſome foreign Force.

Thus *Projectiles* perſevere in their Motions, ſo far as 'till they are retarded by the Reſiſtance of the Air, and the Cauſe of Gravity; and thus a Top, whoſe Parts, by Coheſion, are continually drawing one another out of their Rectilinear Motion, only ceaſes to run round, becauſe reſiſted by the Air, and the Friction of the Plane whereon it moves. And thus the larger Bodies of the Planets and Comets preſerve their progreſſive, circular Motion a long time undiminiſh'd, in Regions void of all ſenſible Reſiſtance.

2. *The Change of Motion is ever proportional to the Moving Force whereby it is effected, and in the Directiou of the Right Line, wherein that Force is impreſs'd.*

If a certain Force produce a certain Motion, a double Force will produce double the Motion, a triple Force triple the Motion, whether it be impreſs'd all at once, or ſucceſſively, by Degrees. And this Motion, ſince it is ever directed to the ſame Point, (with the generating Force) if the Body were in Motion before, is either to be added to it, as if the Motions conſpire, or ſubtracted from it, as where contrary; or added obliquely, as where oblique; and is compounded with it, according to the Determinations of each.

3. *Reaction is always contrary and equal to Action: or the Actions of two Bodies upon one another are always mutually equal, and directed contrary Ways.*

Whatever preſſes or pulls another, is equally preſs'd or pull'd thereby. Thus, if I preſs a Stone with my Finger, the Finger is equally preſs'd by the Stone; if a Horſe draw a Weight by a Rope, the Horſe is equally drawn back by the Weight; for the Rope being equally ſtretch'd each Way, will, with an equal Endeavour to relax itſelf, drive the Horſe towards the Stone, and the Stone towards the Horſe, and will hinder the Progreſs of the one as much as it promotes that of the other.

Again; if any Body, by ſtriking on another, do, in any manner, change its Motion, it will itſelf, by means of the other, undergo an equal Change in its own Motion, by Reaſon of the Equality of the Preſſure.

In theſe Actions the Changes are equal; not thoſe, we mean, of the Velocities, but thoſe of the Motions, the Bodies being ſuppos'd free of any other Impediments: For the Changes of Velocities, which are likewiſe made contrary Ways, inaſmuch as the Motions are equally changed, are reciprocally proportionate to the Bodies.

For a further Illuſtration of the three foregoing Laws of Motion take what follows:

As to the firſt of thoſe Laws of Motion, *That all Bodies do perſevere in the ſame State of Reſt or Moving*, &c. conſider how inviolably this Law is obſerv'd by Natural Agents: For it never has yet been obſerv'd that any Body did bring itſelf from *Reſt* to *Motion*; nor that ever any Body in *Motion* did bring itſelf to *Reſt*; nor that ever any Body in Motion alter'd its Courſe of itſelf: But that there were always evident Cauſes, where-ever ſuch Caſes have happen'd.

If it were ſo, that the Bodies of themſelves did change their Places, then all Things would run into Confuſion; nor would there be any certain Means to regulate the Univerſe. It is certain, that *Projectiles* would for ever move on the ſame ſtrait Line, were not their own Motion ſtopp'd by the *Air*, their own *Gravity*, or the *Ruggedneſs* of the Place on which they mov'd; or if ſome Body by a different Direction did not alter their Courſe. For Inſtance, a Top, as we juſt now mention'd; whoſe Parts, by their Coheſion, hinder one another's Rectilinear Motions, if the Air did not gradually impair its Motion, would for ever turn round.

Natural Bodies conſiſt of a Maſs of Matter which can never alter its State of itſelf; and Bodies that are once at Reſt, muſt continue ſo, till ſome new Force put them into Motion. If Bodies are once in Motion, the ſame Energy will continue them in Motion, and drive them forwards with the ſame Direction.

And beſides, There is in Matter a *Paſſive Principle*, which by Sir *Iſaac Newton* is aptly call'd, The *Vis Inertiæ*; by which Principle, Bodies do to the utmoſt of their Power reſiſt any Change or Alteration of their State, whatever it be, either of *Reſt*, *Motion*, or its *Direction*; and this Reſiſtance is always equal in the ſame Body; and in different Bodies is proportional to the Quantity of Matter they contain.

There is as much Force requir'd to ſtop a Body in Motion, as is requir'd to put it into Motion, and on the contrary: And therefore ſince the ſame Body reſiſts equally the contrary equal Changes of the State; this Reſiſtance will as powerfully operate to keep a Body in *Motion*, as to keep it at *Reſt*, and by conſequence it can never change its State of *Reſt*, *Motion*, or *Direction* of itſelf: For to change its Direction, and of itſelf to move itſelf another Way, is one and the ſame Thing; ſo that *Matter* of itſelf is ſo far indifferent as to *Motion* or *Reſt*, that it is not inclin'd more to one than it is to the other; and does reſiſt a Change from *Reſt* to *Motion*, as much as it does from *Motion* to *Reſt*.

This Paſſive Principle in Matter, or *Vis Inertiæ*, is very conſpicuous in the Motion of a Veſſel full of Liquor upon a Horizontal Plane; for at the firſt, while the Veſſel is in Motion along the Plane, the Liquor in it ſeems to move with a Direction contrary to that of the Veſſel, the Water riſing on the hinder Side of the Veſſel.

This is not becauſe there is any ſuch Motion impreſs'd upon the Water, but becauſe the Water endeavouring by its *Vis Inertiæ* to continue in its State of *Reſt*, the Veſſel is not able to communicate its Motion to it immediately, becauſe of the Bulk and fluid State of it; but the Water perſeveres in its State of Reſt, while the Veſſel makes forward, and ſo ſeems to move a contrary Way. But as ſoon as the Water has the Motion of the Veſſel intirely communicated to it, and begins to move with a Velocity equal to that of the Veſſel; if you ſtop the Veſſel on a ſudden, the Water ſtill continues its Motion, and daſhes over the Sides of the Veſſel.

This *Vis Inertiæ*, or Paſſive Principle, is eſſential to Matter; for it neither can be depriv'd of it, nor intended or remitted in the ſame Body, but is always in Proportion to the Quantity of Matter Bodies do contain.

From what has been before ſaid, the following Corollaries may be deduc'd:

1. It appears plain from hence, That neither any Particle of Matter, or Combination of Particles, *i. e. No Body*, can either move of it, or themſelves, or alter the Direction of their Motion by themſelves: For *Matter* is not endow'd with Self-Motion, nor with a Power to alter the Courſe in which it is put; but is merely Paſſive, and muſt of itſelf for ever continue in that State and Courſe that it is ſettled in, for ever; and if it cannot move of itſelf, it never can of itſelf alter its Courſe, when it is in Motion: For of itſelf to alter its Courſe, is no other than to move of itſelf after a particular Manner.

2. It is alſo plain from hence, that no Body, when it is once put *into Motion*, will of itſelf naturally move in a curve Line. All Motion is naturally forward in the ſame ſtrait Line with the Direction of the Moving Force; but whatſoever does move in a curve Line, muſt alter its Direction in every Point; and therefore no Body can naturally move of itſelf in a curve Line.

3. Hence it appears, that thoſe great Bodies, the *Planets*, their *Satellites*, and *Comets* (tho' they are at firſt put into Motion) do not naturally, and of themſelves, move in their reſpective Orbits, which are curve Lines, returning into themſelves; but are kept in them by ſome attracting Force; which if it were once ſuſpended, they would run out in right Lines for ever: And of Conſequence, the Motions of theſe vaſt Bodies in their Orbits depend abſolutely upon this attracting Force. And thence it is,

4. That neither *Motion* nor *Reſt* (not one of them particularly) is eſſential to Matter: That is as much as to ſay, that Matter is indifferent as to either of theſe particularly, and does no leſs reſiſt its being chang'd from *Reſt* to *Motion*, than it does being chang'd from *Motion* to *Reſt*. And as any Force will impreſs ſome Degree of *Motion* on a reſting Body; ſo, in like manner, the ſame Degree of Force being impreſs'd at the ſame Time with a contrary Direction, will bring it again to *Reſt*; but it is not abſolutely neceſſary, as to the Being of Matter, that it be either in *Motion* or *Reſt*. For, let Matter be in which of theſe States ſoever, it will ſtill be Matter. And ſo, ſince the *Vis Inertiæ* or paſſive Principle is eſſential to Matter, it thereby becomes indifferent as to *Reſt* or *Motion*, and is equally ſuſceptible of either, according as the external Force urges it.

5. Hence may be demonſtrated the Neceſſity of a *Vacuum*, or Space diſtinct from Matter: For ſince it is ſo that all Bodies do by their *Vis Inertiæ*, to the utmoſt of their Power, reſiſt any Manner of Change or Alteration of their State either of *Reſt* or *Motion*; and ſince the Reſiſtance is always equal in the ſame Body, or the ſame, and in different Bodies, is proportionable to the Quantity of Matter whereof they conſiſt; and ſince, by Conſequence, if two Bodies which contain equal Quantities of Matter, moving with equal Quickneſs in contrary Directions, ſo that they ſtrike directly upon one another, they will for certain both *reſt* or *ſtop* at the Point of their Meeting or Concourſe; as alſo it being demonſtrable, That two Bodies moving with equal Celerities contrary one to the other, and both reſting where they meet, are equally heavy; it then follows of Neceſſity, that two Bodies, which contain equal Quantities of Matter, are equally heavy: And if this be allow'd, if there were two Spheres of equal Diameters, and there were no Vacuities in Bodies, they would contain equal Quantities of Matter, and of Conſequence would be of equal Weight; *i. e.* Two Spheres, the one of *Wood*, and the other of *Gold*, would have the ſame ſpecifick Gravities: But this being contradicted by Experience, Vacuities in the Sphere of Wood muſt of Neceſſity be admitted to anſwer for the Difference of their Gravities.

As to the Second, *That the Changes made in the Motion of Bodies are always proportional*, &c. that may be illuſtrated by the following Conſiderations:

Effects are always in Proportion to their adequate Cauſes; and if any Degree of *Force* produce any Degree of *Motion*, then it follows, that a double Degree of the ſame Force will produce a double Degree of Motion; and a three-fold Degree of the ſame Force, a three-fold Degree of the ſame Motion; and ſo on: And this Motion muſt of Neceſſity proceed in the ſame Direction as that of the Force moving, ſince the Motion is cauſed only by it; and becauſe by the former Law, Bodies which are in Motion cannot change their Directions of themſelves; ſo that except their Courſe be alter'd by ſome new Force, the Bodies muſt proceed in the ſame Direction with that of the moving Courſe. And if a Body was before in Motion, the Motion which ariſes from that impreſs'd Force, if in the ſame Direction, does ſo much increaſe the former Motion; if it has a contrary Direction, it deſtroys a Part of the former Motion, equal to that which is impreſs'd; when it has a Direction oblique to the former Motion, it is either added to or ſubtracted from the former Motion, according as the Motion, ariſing from a Compoſition of theſe two, is determin'd.

From what has been ſaid, it plainly appears, That in the preſent Conſtitution of Things, there can be no perpetual Motion. By a *perpetual Motion* you are to underſtand an uninterrupted Communication of the ſame Degree of Motion, from one Part of Matter to another in a Circle: Not as Bodies, which are put into a Motion, do for ever continue in the ſame, unleſs ſo far as they are reſiſted or ſtopp'd by other Bodies; but a Circulation of the ſame Quantity of Motion, ſo as it returns perpetually undiminiſh'd from the firſt Mover.

For, Motion produced (by the Law) is but proportionable to the Force generating; and all the Motions which are perform'd on this Globe, being perform'd in a reſiſting Fluid (the Air) a conſiderable Quantity of this Motion muſt neceſſarily be ſpent in the Communication, on this *Medium*, and ſo of Conſequence it is impoſſible that the ſame Quantity of Motion ſhould return undiminiſh'd upon the firſt Mover; which is neceſſary, in order to a *perpetual Motion*.

Beſides, ſuch is the Nature of material Organs, that a greater or leſſer Degree of Friction cannot be avoided, altho' the Machine ſhould be framed according to the moſt exact Principles of *Geometry* and *Mechanicks*, there not being in Nature any Congruity that is perfect, or Smoothneſs that is exact; the Manner of Coheſion of Bodies; the ſmall Proportion the ſolid Matter bears to the Vacuities in them, not admitting of them ſo to be. And beſides, an ordinary Microſcope will diſcover how very imperfect our moſt finiſh'd Mechanick Performances are.

Now as the Things before-mention'd muſt very conſiderably diminiſh the Force communicated, it is impoſſible there ſhould be a perpetual Motion, except the Force communicated were greater than the Force generating, by ſo much as to make amends for the Diminution made therein by all theſe Cauſes; ſo that the Motion impreſs'd may never return undiminiſh'd to the *firſt Mover*: But that being contrary to this Law, it is evident, that the Motion muſt decreaſe, till at laſt it ſtops, and ſo of conſequence, in the preſent State of Things, there cannot be any perpetual Motion.

As to the Third Law, *That Repulſe and Re-action is always equal to Impulſe or Action*, &c.

To illuſtrate this, conſider, That whatſoever preſſes or draws another, is as much preſs'd or drawn by that other. If a Stone be preſs'd by the Finger, the Finger is preſs'd by the Stone again. If an Anvil be ſtruck with a Hammer, the Hammer is ſtruck by the Anvil with equal Force. If a Horſe draw a Stone forward by a Rope, the Stone does equally draw back the Horſe; for the Rope being diſtended equally both Ways, does equally act upon both; as we intimated before.

That the Steel draws the Load-ſtone as much as the Magnet draws the Steel, appears evidently, by making both ſwim in Water. And in the Deſcent of heavy Bodies, the Earth is attracted by the Stone, as much as the Stone is by the Earth; *i. e.* the Earth gravitates towards the Stone, as much as the Stone does towards the Earth: and the Motions, which are produced by both theſe Gravitations, are equal in both, excepting that the Stone is altogether inconſiderable, compared to the Bulk of the Earth; and ſo of Conſequence the Velocity of the Motion of the Earth towards the Stone is inconſiderable, compared to the Motion of the Stone towards the Earth; and therefore the Earth's Motion towards the Stone is inſenſible.

And univerſally in all the Actions of Bodies; if one Body act on another, and change its Motion any Manner of Way, that other Body will make the ſame Change in the Motion of this Body, with a contrary Direction; ſo that there are equal Changes made by theſe Actions, of the Motion, but not of the Velocities: For the Changes which are made on the Velocities in contrary Directions are in a Proportion, which is reciprocal to the Bodies.

NEBULOSE or **NEBULOUS**, ſignifies cloudy, miſty, foggy, hazy.

NECTARINE, [probably ſo call'd of *Nectar*, the Poetical Drink of the Gods] Nectarine.

This Fruit ſhould have been placed under the Article of *Peaches*, to which it properly belongs, differing from them in nothing more than in having a ſmooth Rind, and the Fleſh being firmer. Theſe the *French* diſtinguiſh by the Name of *Brugnon*, as they do thoſe *Peaches* which adhere to the Stone, by the Name of *Pavie's*, retaining the Name of *Peſche* to only ſuch as part from the Stone: But ſince the Writers in Gardening have diſtinguiſh'd this Fruit by the Name of *Nectarine* from the *Peaches*, ſo I ſhall follow their Example, leſt by endeavouring to rectify their Miſtakes, I ſhould render myſelf leſs intelligible to the Reader. I ſhall therefore mention the ſeveral Sorts of this Fruit which have come to my Knowledge:

1. *Fairchild's Early Nectarine.* This is one of the earlieſt ripe *Nectarines* we have: It is a ſmall round Fruit, about the Size of the *Nutmeg Peach*, of a beautiful red Colour, and well flavour'd; it ripens the Middle of *July*.

2. *Elruge Nectarine* is a middle-ſized Fruit of a dark-red or purple Colour next the Sun, but of a pale yellow or greeniſh Colour towards the Wall; it parts from the Stone, and has a ſoft melting Juice. This ripens in the End of *July*.

3. *Newington Nectarine* is a fair large Fruit, (when planted on a good Soil) of a beautiful red Colour next the Sun, but of a bright yellow towards the Wall; it has an excellent rich Juice, the Pulp adheres cloſely to the Stone, where it is of a deep red Colour. This ripens the Beginning of *Auguſt*.

4. *Scarlet Nectarine* is ſomewhat leſs than the laſt, of a fine red or ſcarlet Colour next the Sun, but loſes itſelf in paler red towards the Wall. This ripens in the End of *July*.

5. *Brugnon* or *Italian Nectarine* is a fair large Fruit, of a deep red Colour next the Sun, but of a ſoft yellow towards the Wall; the Pulp is firm, of a rich Flavour, and cloſely adheres to the Stone, where it is very red. This ripens in the Middle of *Auguſt*.

6. *Roman Red Nectarine* is a large fair Fruit, of a deep red or purple Colour towards the Sun, but has a yellowiſh Caſt next the Wall; the Fleſh is firm, of an excellent Flavour, cloſely adhering to the Stone, where it is very red. This ripens in the Middle of *Auguſt*.

7. *Murry Nectarine* is a middle-ſized Fruit, of a dirty red Colour on the Side next the Sun, but of a yellowiſh green towards the Wall; the Pulp is tolerably well flavour'd. This ripens the Middle of *Auguſt*.

8. *Golden Nectarine* is a fair handſome Fruit, of a ſoft red Colour next the Sun, but of a bright yellow next the Wall; the Pulp is very yellow, of a rich Flavour, and cloſely adheres to the Stone, where it is of a faint red Colour. This ripens the Beginning of *September*.

9. *Temple's Nectarine* is a middle-ſized Fruit, of a ſoft red Colour next the Sun, but of a yellowiſh green towards the Wall; the Pulp is melting, of a white Colour towards the Stone, from which it parts, and has a fine poignant Flavour. This ripens in the Middle of *September*.

10. *Peterborough* or *Late Green Nectarine* is a middle-ſized Fruit, of a pale green Colour on the Outſide next the Sun, but of whitiſh green towards the Wall; the Fleſh is firm, and, in a good Seaſon, well flavour'd. This ripens at the End of *September*.

There are ſome Perſons who have mention'd more Sorts than I have here ſet down, but I much doubt whether they are different from thoſe here mention'd, there being ſo near Reſemblance between the Fruits of this Kind, that it requires a very cloſe Attention to diſtinguiſh them well, eſpecially if the Trees grow in different Soils and Aſpects, which many Times alters the ſame Fruit ſo much as hardly to be diſtinguiſh'd by Perſons who are very converſant with them; therefore in order to be thoroughly acquainted with their Differences, it is neceſſary to conſider the Shape and Size of their Leaves, the Size of their Flowers, their Manner of Shooting, *&c.* which is many Times very helpful in knowing of theſe Fruits: All which, together with a more ample Deſcription of them, as alſo the true Shape of the Flowers, Leaves, and Fruits engraven on Copper Plates, and painted from the Life, will, I hope, be exhibited by the Society of Gardeners, for thoſe who are curious to know their ſeveral Diſtinctions.

The Culture of this Fruit differing in nothing from that of the *Peach*, I ſhall forbear mentioning any Thing on that Head in this Place, to avoid Repetition, but refer the Reader to the Article *Perſica*, where there is an ample Account of their *Planting*, *Pruning*, &c.

NEMORAL, ſignifies belonging to a Wood or Grove.

NEMOROSE, ſignifies full of Woods or Groves.

NEPETA. *Vide* Cataria.

NERIUM, The Oleander, or Roſe-bay.

The *Characters* are;

The Flowers are monopetalous and funnel-ſhaped, divided into five Segments at the Top; out of the Flower-cup ariſes the Pointal, which becomes a taper Fruit, or Pod, divided into two Cells by an intermediate Partition, and filled with flat Seeds, which have Down adhering to them.

The *Species* are;

1. NERIUM *floribus rubeſcentibus. C. B. P.* Oleander with red Flowers.

2. NERIUM *floribus albis. C. B. P.* Oleander with white Flowers.

3. NERIUM *Indicum anguſtifolium floribus odoratis ſimplicibus. H. L.* Narrow-leaved Indian Oleander, with ſingle ſweet-ſcented Flowers.

4. NERIUM *Indicum latifolium, floribus odoratis plenis. H. L.* Broad-leaved Indian Oleander, with double ſweet-ſcented Flowers.

5. NERIUM *Indicum, flore variegato odorato pleno. H. Amſt.* Indian Oleander, with double ſweet-ſcented variegated Flowers, *commonly called* South-Sea Roſe.

6. NERIUM *floribus ex albo & roſeo variegatis. T. Cor.* Oleander or Roſe-bay with a white Flower ſtriped with Red.

7. NERIUM *Indicum latifolium, flore rubro majore.* Broad-leaved Indian Oleander, with a larger red Flower.

The firſt and ſecond Sorts are very common in the *Engliſh* Gardens, where they are preſerved in Pots or Tubs, and placed among *Myrtles*, *Oranges*, &c. in the Green-houſe: They are pretty hardy Plants, and only require to be ſheltered from hard Froſt; for in moderate Winters I have known them ſtand abroad in warm Borders, but in hard Froſts they are often deſtroyed, if expoſed thereto.

Theſe may be placed in Winter in an ordinary Green-houſe among *Bays*, &c. which require a great Share of free Air, and only want Protection from hard Froſts, where they will thrive better, than if placed in a warmer Houſe, or kept too cloſe in Winter. They are propagated from Suckers, which they ſend forth from their Roots in great Plenty, or by laying down their tender Branches, which will take Root in one Year: The Time for laying them down is in the Beginning of *April*, and the Year following the Layers ſhould be taken off, when they ſhould be planted into Pots filled with freſh rich Earth, obſerving to place them in the Shade, until they have taken Root, after which they may be expoſed with *Myrtles*, *Geraniums*, &c. in ſome Place where they may be ſheltered from ſtrong Winds. During the Summer-ſeaſon they muſt be plentifully water'd, otherwiſe they will make but poor Progreſs, and produce very few Flowers; but if they are conſtantly ſupplied with Water, they will make a fine Appearance during the Months of *July* and *Auguſt*, when they will be covered with Flowers. In Winter they muſt be frequently refreſhed with Water, but it ſhould not be given them in large Quantities at that Seaſon.

The third, fourth, fifth, and ſeventh Sorts are tenderer than the others; therefore require a warmer Situation in Winter, nor muſt they be expoſed to the open Air in Summer; for if they are placed abroad, their Flowers will not open. So that in Winter they ſhould be placed in a warm Green-houſe, and in Summer they ſhould be removed into an airy Glaſs-caſe, where they may be defended from the Cold of the Nights; but in the Day-time they ſhould have a large Share of free Air, obſerving to give them Plenty of Water, which will cauſe them to produce their Flowers large, and in great Quantities. Theſe Plants are Natives of the *Spaniſh* *Weſt-Indies*, from whence they were brought into the *Engliſh* Colonies in *America*, where they were planted for the Beauty of their Flowers; but ſince the Inhabitants have found they deſtroy their Cattle which have browzed on the Plants, they uſually root them out near their Settlements.

Theſe Sorts alſo flower in *July* and *Auguſt*, when they make a beautiful Appearance; for they produce their Flowers in very large Bunches, and the Flowers of the fourth and fifth Sorts are very large and double, and ſmell greatly like thoſe of white Thorn, ſo that they deſerve a Place in every good Green-houſe.

Theſe Plants may be propagated from Suckers or Layers, as the two former; but they do not produce Suckers in ſo great Plenty as thoſe in this Country. They all grow naturally on the Sides of Rivers, and moiſt Places; ſo that they muſt have Plenty of Water.

The ſixth Sort was diſcovered by Dr. *Tournefort* in the *Levant*. This is very rare at preſent in *Europe*, but is as hardy as the common Sort, and may be propagated in the ſame Manner.

The third Sort produces fleſh-coloured Flowers, of the ſam Size and Shape as thoſe of the common Sort; but have a ver muſky Scent, ſo that they perfume the Houſe in which the are placed, when they are in Flower. The Flowers of thi Kind will not open fair, if they are expoſed in the open Air ſo that they ſhould be placed in a Stove or Glaſs-caſe in Summer, with the two double Kinds, and the ſeventh Kind, wher they will make a beautiful Appearance, and continue a lon Time in Flower.

Al

All the Sorts ſhould be ſhifted every Spring, about the Beginning of *April*, when the Suckers, or Layers, which are rooted, muſt be taken off, and planted into Pots filled with light rich Earth. The Roots of the old Plants muſt be trimmed, and as much of the Earth taken from their Roots, as may be done without Injury to the Plants, and the Pots filled with freſh rich Earth, which will encourage the Plants to produce a great Number of Flowers.

NERVES, are long tough Strings, which run either acroſs or lengthways in the Leaves of Plants.

NICOTIANA, [this Plant takes its Name of *James Nicotius*, Counſellor to *Francis* II. King of *France*, who, in the Year 1560, being an Ambaſſador in the Court of *Portugal*, bought this Plant of a *Dutchman*, that brought it from *America*, and ſent it to Queen *Catharine de Medicis* in *France*; where being ſown, it produced Seeds: The *Indian* Inhabitants call it *Tabac*, becauſe it grew in an Iſland call'd *Tabaco*. The leſſer Sort is call'd *Hyoſcyamus*, becauſe it agrees with this Plant; but the Flowers differ, altho' the Virtues are the ſame: It is alſo call'd *Priapeia*] Tobacco.

The *Characters* are;

The Flower conſiſts of one Leaf, is Funnel-ſhaped, and divided at the Top into five deep Segments, which expand like a Star; the Ovary becomes an oblong or roundiſh membranaceous Fruit, which is divided into two Cells by an intermediate Partition, and is fill'd with ſmall roundiſh Seeds.

The *Species* are;

1. Nicotiana *major, latifolia. C. B. P.* The greater broad-leav'd Tobacco.
2. Nicotiana *major, anguſtifolia. C. B. P.* The greater narrow-leav'd Tobacco.
3. Nicotiana *major, anguſtifolia, perennis. Jeſſieu.* The greater narrow-leav'd perennial Tobacco.
4. Nicotiana *minor. C. B. P.* The leſſer *or* common *Engliſh* Tobacco.
5. Nicotiana *minor, foliis rugoſioribus amplioribus. Vaill.*
6. Nicotiana *major, foliis latiſſimis & rugoſioribus, floribus rubicundis.* Greater Tobacco, with very broad and rough Leaves, and reddiſh Flowers, *commonly called* Oronoko.
7. Nicotiana *major latifolia, floribus albis, vaſculo brevi. Martyn. Cent.* 1. Greater broad-leav'd Tobacco, with white Flowers, and a ſhort Seed-veſſel.
8. Nicotiana *humilis, primulæ veris folio. Houſt.* Dwarf Tobacco, with a Primroſe Leaf.
9. Nicotiana *minor, folio cordiformi, tubo floris prælongo. Feuillée.* Smaller Tobacco with a Heart-ſhaped Leaf, and a Flower with a longer Tube.

The firſt Sort is known by the Planters in *America* under the Title of *Oronooka*; of which there ſeems to be two different Kinds, varying in the Largeneſs and Texture of their Leaves, ſome having very broad, rough, roundiſh Leaves; and others are narrower, ſmoother, and do terminate in a Point: but neither of theſe Sorts are eſteem'd by the *American* Planters, becauſe the Produce of this (tho' it is much greater than the narrow-leav'd Sort) yet it is not near ſo much eſteem'd by the *Engliſh*. This Sort is commonly cultivated in *Germany*, about *Hanover* and *Straſburgh*, and is ſomewhat hardier than the narrow-leav'd Sorts, which renders it preferable to that for cultivating in Northern Climates.

This Plant is order'd by the College of Phyſicians for Medicinal Uſe, and is what ſhould be made uſe of for the *Unguentum Nicotianæ*, (or Ointment of *Tobacco*) tho' many Times the Leſſer or *Engliſh Tobacco* is brought to Market for that Purpoſe.

The narrow-leav'd Sort is commonly call'd the *Sweet-ſcented Tobacco*, from its having a much more agreeable Scent, when ſmoak'd, than the broad-leav'd Sort; the Smoak of which is very offenſive to moſt Perſons who have not been accuſtom'd to it. This Sort is cultivated in great Plenty in *Virginia*, *Cuba*, *Braſil*, and ſeveral other Parts of *America*; from whence it is brought to moſt Parts of *Europe*, but eſpecially to *England*, it being prohibited to be cultivated in this Country, leſt his Majeſty's Revenues ſhould be thereby leſſened: But as a ſmall Quantity is permitted to be cultivated for Medicinal Uſe, I ſhall briefly ſet down the Method how it may be propagated, ſo as to have fair large Leaves for that Purpoſe.

The Seeds of this Plant muſt be ſown upon a moderate Hot-bed in *March*; and when the Plants are come up, they ſhould be tranſplanted into a new Hot-bed of a moderate Warmth, about four Inches aſunder each Way, obſerving to water and ſhade them until they have taken Root: After which you muſt let them have Air in Proportion to the Warmth of the Seaſon, otherwiſe they will draw up very weak, and be thereby leſs capable of enduring the open Air: You muſt alſo obſerve to water them frequently, (but while they are very young it ſhould not be given to them in too great Quantities) tho' when they are pretty ſtrong, they will require to have it often and in plenty.

In this Bed the Plants ſhould remain until the Beginning of *May*; by which Time (if they have ſucceeded wel) they will touch each other; therefore they ſhould be enured to the open Air gradually: After which they muſt be taken up carefully, preſerving a large Ball of Earth to each Root, and planted into a rich light Soil, in Rows two Feet aſunder, and the Plants a Foot Diſtance in the Rows, obſerving to water them until they have taken Root; after which they will require no farther Care (but only to keep them clear from Weeds) until the Plants begin to ſhew their Flower-ſtems; at which Time you ſhould cut off the Tops of them, that their Leaves may be the better nouriſh'd, whereby they will be render'd larger, and of a thicker Subſtance. In *Auguſt* they will be full grown, when they ſhould be cut for Uſe; for if they are permitted to ſtand longer, their under Leaves will begin to decay.

The Perennial Sort was brought from the *French* Settlements in the *Weſt-Indies* into the *Royal Garden* at *Paris*, where it is cultivated in ſmall Quantities for making Snuff. The Seeds of this Kind I received from Monſieur *de Jeſſieu*, Demonſtrator of the Plants in the *Royal Garden*: It has ſucceeded very well in the *Phyſick Garden*, and abides the Winter in a common Green-houſe without artificial Heat.

The two ſmaller Sorts of *Tobacco* are preſerved in Botanick Gardens, for Variety, but are ſeldom propagated for Uſe. The firſt Sort is found growing upon Dunghils in divers Parts of *England*. Theſe are both very hardy, and may be propagated by ſowing their Seeds in *March*, upon a Bed of light Earth, where they will come up, and may be tranſplanted into any Part of the Garden.

The ſixth Sort is the moſt common in *England*, and is generally raiſed by the Gardeners near *London*, who ſupply the Markets with Pots of Plants to adorn Balconies and Shop-windows in the City. This Sort, when raiſed early in the Spring, and planted in a rich Soil, will grow to the Height of fifteen or ſixteen Feet, provided the Plants are duly water'd in dry Weather. This Kind is not ſo much cultivated in *Virginia*, as the common broad-leav'd Sort, becauſe it is a much ſtronger Tobacco, ſo is not eſteemed by the *Engliſh*.

The ſeventh Sort of Tobacco was found growing wild in the Iſland of *Tobago*, by Mr. *Robert Millar*, Surgeon, who ſent the Seeds into *Europe*, which have ſucceeded in ſeveral curious Gardens. This Sort produces broader and rounder Leaves, than the common Sort, which are leſs veined, and very glutinous. The Plants uſually grow about five Feet high, and the Flowers of this are white, in which it differs from all the other Sorts.

Theſe two Sorts are both of them as hardy as the common broad-leav'd Kind, and are propagated by Seeds in the ſame Manner as hath been above directed.

The eighth Sort was diſcovered by the late Dr. *William Houſtoun* at *La Vera Cruz*; from whence he ſent the Seeds and dried Samples of the Plants. This Sort is very different from all the other Kinds in the Manner of its Growth: For the Leaves of this Plant grow in Tufts near the Ground; out of the Middle of theſe Leaves, ariſes the Flower-ſtem, which is naked, having no Leaves upon it, to the Height of eighteen Inches or a little more, and divides into many ſmall Branches, on which ſtand the Flowers on ſhort Foot-ſtalks, which are of a greeniſh yellow Colour.

The ninth Sort was diſcovered by Father *Feuillée*, in the *Spaniſh Weſt-Indies*. This Sort commonly grows between three and four Feet high, and divides into ſeveral ſmall Branches; the Leaves of this Sort are ſhaped like a Heart, and the Flowers are of a greeniſh yellow Colour.

Theſe two Sorts are ſomewhat tenderer than the former, ſo ſhould be ſown early in the Spring on a Hot-bed; and when the Plants come up, they ſhould be tranſplanted on another moderate Hot-bed, where they muſt be duly water'd, and ſhould have a large Share of free Air in warm Weather; and when the Plants have obtained a good Share of Strength, they ſhould be tranſplanted into ſeparate Pots, and plunged into a moderate Hot-bed to bring them forward; about the Middle of *June* ſome of the Plants may be ſhaken out of the Pots, and planted into Beds of rich Earth; but it will be proper to keep two Plants of each Kind in Pots, which may be placed in the Stove, (in caſe the Seaſon ſhould prove bad) that they may ripen their Seeds, ſo that the Species may be preſerved.

NIGELLA, [ſo call'd, as tho' *Nigrella*, from the Colour of its Seed, becauſe the Seeds of this Plant are for the moſt part black. It is alſo call'd *Melanthium*, of μέλας, *black*, and ἄνθος, a *Flower*; q. d. *black Flower*, altho' the Flower is not black: It is alſo call'd *Melaſpermum*, of μέλας, *black*, and σπέρμα, *Seed*] Fennel-Flower *or* Devil in a Buſh.

The *Characters* are;

The Flower-cup conſiſts of five Leaves, which expand in form of a Star, and branch out into many other ſmall narrow Leaves; the Flower conſiſts of many Leaves placed orbicularly, and expand in form of a Roſe, having many ſhort Stamina ſurrounding the Ovary in the Center of the Flower; which Ovary becomes a membranaceous Fruit, conſiſting of ſeveral Cells, which are furniſh'd with Horns on the Top, and are full of Seeds.

The *Species* are;

1. **Nigella** *arvenſis cornuta. C. B. P.* Wild horned Fennel-flower.
2. **Nigella** *latifolia, flore majore, ſimplici cœruleo. C.B.P.* Broad-leav'd Fennel-flower, with a large ſingle blue Flower.
3. **Nigella** *anguſtifolia, flore majore ſimplici cœruleo. C. B. P.* Narrow-leav'd Fennel-flower, with a large ſingle blue Flower.
4. **Nigella** *anguſtifolia, flore majore ſimplici albo. C. B. P.* Narrow-leav'd Fennel-flower, with a large ſingle white Flower.
5. **Nigella** *flore majore, pleno cœruleo. C. B. P.* Double blue Nigella *or* Fennel-flower.
6. **Nigella** *flore minore, ſimplici candido. C. B. P.* Fennel-flower, with a ſmall white ſingle Flower.
7. **Nigella** *flore minore, pleno & albo. C. B. P.* Fennel-flower, with a ſmall double white Flower.
8. **Nigella** *orientalis, flore flavo, ſemine alato plano. T. Cor.* Oriental Fennel-flower, with a yellow Flower, and a flat-wing'd Seed.
9. **Nigella** *Cretica, latifolia, odorata. Park. Theat.* Broad-leav'd ſweet-ſcented *Candy* Fennel-flower.

There are ſome other Varieties of this Plant which are preſerved in ſome curious Botanick Gardens; but thoſe here mention'd are what I have obſerved cultivated in the *Engliſh* Gardens at preſent.

All theſe Plants may be propagated by ſowing their Seeds upon a Bed of light Earth, where they are to remain, (for they ſeldom ſucceed well if tranſplanted;) therefore in order to have them intermix'd amongſt other annual Flowers, in the Borders of the Flower-Garden, the Seeds ſhould be ſown in Patches at proper Diſtances; and when the Plants come up, you muſt pull up thoſe which grow too cloſe, leaving but three or four of them in each Patch, obſerving alſo to keep them clear from Weeds, which is all the Culture they require. In *July* they will produce their Flowers, and their Seeds will ripen in *Auguſt*, when they ſhould be gather'd, and dried; then rub out each Sort ſeparately, and preſerve them in a dry Place.

The Seaſon for ſowing theſe Seeds is in *March*; but if you ſow ſome of them in *Auguſt*, ſoon after they are ripe, upon a dry Soil, and in a warm Situation, they will abide the Winter, and flower ſtrong the ſucceeding Year; by which Method they may be continued in Beauty moſt part of the Summer.

The fifth Sort is that which is moſt commonly cultivated in *England*, the Seeds of which are ſold in the Seed-ſhops; but the other Sorts do deſerve to be preſerved as much as that; for the various Sorts, when rightly intermix'd, do afford an agreeable Variety. They are all annual Plants, which periſh ſoon after they have perfected their Seeds; which if permitted to ſcatter upon the Borders, will come up without any farther Care. The Plants commonly grow about a Foot high, and if they have a good Soil, will ſend forth many Branches, each of which terminates in a Flower.

NIGELLASTRUM. *Vide* Lychnis Segetum major.

NIGHT-SHADE. *Vide* Solanum.

NIL. *Vide* Anil.

NISSOLIA, Crimſon Graſs-Vetch: *vulgo*.

The *Characters* are;

It hath a papilionaceous Flower, like the Lathyrus, *to which this Plant agrees in every reſpect, except the Leaves, which in this are produced ſingly, and are not terminated by Claſpers.*

The *Species* are;

1. **Nissolia** *vulgaris. Tourn.* Common Crimſon Graſs-Vetch.
2. **Nissolia** *Orientalis, flore purpureo. Tourn. Cor.* Eaſtern Graſs-Vetch, with a purple Flower.
3. **Nissolia** *Americana procumbens, folio rotundo, flore luteo. Houſt. American* trailing Vetch, with a round Leaf, and a yellow Flower.

The firſt Sort is found wild in ſeveral Parts of *England*, growing commonly by the Sides of Foot-paths, but is not very common near *London*: I have gather'd it in a Field juſt before you come to *Putney Common*, on the Left-hand Side of the Road, under the Hedge which parts the Field from the Road.

This Plant may be cultivated by ſowing the Seeds in *Auguſt*, ſoon after they are ripe, on a dry Soil, and in a warm Situation, where they will riſe ſoon after, and endure the Cold of our Climate very well, and flower early the ſucceeding Spring; but if you ſow the Seeds in the Spring, the Plants commonly decay before they come to flower, as I have ſeveral times experienced: Therefore you need only to let the Seeds fall upon the Ground when they are ripe, and they will grow without any farther Trouble, but only to keep them clear from Weeds.

The Flowers of this Plant are ſmaller than thoſe of the *Sweet Pea*, but are much the ſame in Shape, and of a fine Scarlet Colour; ſo that being intermix'd in large Borders amongſt theſe and other annual Plants, it makes a pretty Variety, and deſerves a Place in every good Garden.

The ſecond Sort was diſcovered by Dr. *Tournefort* in the *Levant*: This is a hardy Plant, and may be ſown in the full Ground, and treated as the common Sort; but the third Sort is more tender. This was diſcovered by the late Dr. *William Houſtoun*, near *La Vera Cruz*. The Seeds of this Plant ſhould be ſown on a moderate Hot-bed early in the Spring; and when the Plants are come up, they ſhould be frequently refreſhed with Water, and in warm Weather the Glaſſes of the Hot-bed ſhould be raiſed a little every Day, to admit freſh Air to the Plants, which will cauſe them to grow ſtrong, and in about a Month's Time they will be fit to tranſplant; when they ſhould be taken up carefully, and each planted into a ſmall Pot filled with light rich Earth, and then plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun in the Heat of the Day, until they have taken new Root; after which Time they ſhould have a large Share of Air in warm Weather, and be frequently refreſhed with Water. The Plants may remain in the Hot-bed until the Autumn, when the Cold begins to come on; at which Time they ſhould be removed into the Stove, and plunged into the Bark-bed, where if they are carefully managed, they will live thro' the Winter, and flower early the following Summer, ſo will perfect their Seeds.

NITRE, is a Kind of Salt impregnated with Abundance of Spirits out of the Air, which renders it volatile.

Monſieur *Le Clerc* gives us the following Account of it:

In *Egypt* they make a great Quantity of it, but it is not ſo good; for it is duſky, and full of Knots and Stones.

It is made almoſt in the Manner that Salt is made, but only that they uſe Sea-Water in their Salt-works, and the Water of *Nile* about their *Nitre*.

When the *Nile* retires, their *Nitre-pits* ſtands ſoaking for forty Days together; but as the *Nitre* is grown firm, they are in haſte to carry it off, leſt it ſhould melt again in the Pits: they pile it up in Heaps, and it keeps very well.

The *Memphian Nitre* grows ſtrong, and there are ſeveral Pits of Stone thereabouts: Out of theſe they make Veſſels, and ſome they melt down with Sulphur among their Coals.

This ſame *Nitre* they uſe alſo about ſuch Things as they would have to laſt a long Time.

The Proof of the Goodneſs of *Nitre* is, that it be very light, very friable, and very near of a purple Colour.

There is but little Difference between the *natural* and *artificial Nitre*; that the one refines itſelf, and the other is refined by Art, as Salt; and, indeed, all *Nitre* is a kind of Salt, and hardly differs from Salt, properly ſo call'd, farther than in theſe reſpects; that well-refined *Nitre* is more acid and lighter than Salt, and eaſily takes Fire.

The Reaſon of which Difference, he ſays, ſeems to be,

1. That the Angles at both Ends of the oblong Particles of *Nitre*, are ſhorter than the Angles of the ſaline Particles.

2. That the Particles of *Nitre* are finer, and fuller of Pores; which, when the Particles of Fire get in, they ſoon put the nitrous Particles into a Hurry, till they break to pieces, and turn to Flame.

3. *Nitre* exceeds Salt in Lightneſs, becauſe the *ſaline* Particles contain more homogeneous Matter in the ſame Compaſs, than the *nitrous* do.

Dr. *Liſter* tells us, he has view'd the Particles of *Nitre* thro' a *Microſcope*, and found them to have ſix Angles, Parallelogram Sides, and pointed like a Pyramid at one End.

Some Authors are of Opinion, that the *nitrous Salts* ſeem to be aſſigned by Nature chiefly for the Growth of Plants.

Others differ from them in Opinion, and ſay, that when *Nitre* is contiguous to Plants, it rather deſtroys than nouriſhes them: But yet they allow, that *Nitre* and other *Salts* do certainly looſen the Earth, and ſeparate the concreted Parts of it, and, by that means, fit and diſpoſe them to be aſſumed by Water, and carried up into the Seed or Plant, for its Formation and Augment.

It is obſervable, how all Salts are wrought upon by *Moiſture*; how eaſily they liquidate and run with it: And when theſe are drawn off, and have deſerted the Lumps wherewith they were incorporated, thoſe muſt moulder immediately, and fall aſunder of courſe.

The hardeſt Stone, if it has any Salt mix'd with the Sand of which it conſiſts, upon being expoſed to an humid Air, in a ſhort Time diſſolves and crumbles all to pieces; and much more will clodded Earth or Clay, which is not of near ſo compact and ſolid a Conſtitution as ſtone is.

If the Earth be never ſo good, and fit for the Production of Vegetables, little will come of it, unleſs the Parts of it be ſeparated and looſe; and for this Reaſon is the Ground digged, ploughed, and harrowed, and the Clods broken: And it is this Way that *Nitre*, *Sea-Salt*, and other *Salts* promote Vegetation.

A certain Gentleman has given a Relation, That he dwelling in the Country, near a *Petre-houſe*, where ſuch *Salt-petre* as is brought from Abroad is boiled and refined, to make Gunpowder; this being ſo near as to communicate the Steam of the *Nitre* to the greateſt Part of the Orchard and Garden; and tho' ſome were of Opinion, that it injured his Trees and Plants, yet he found that it had a contrary Influence upon his Orchard, *&c.* in that it never fail'd to bring him a plentiful Crop of Fruit every Year, altho' thoſe about him had but very little, or ſcarce any, notwithſtanding his Orchard, *&c.* was not leſs expoſed to blighting Winds by its natural Situation, than the other Orchards in the ſame Town. From whence he judged, that the *nitrous* Vapour which mixes with the Air that ſurrounds his Orchard, prevents Blights, and is noxious to the Caterpillars.

The Lord *Bacon*, in his *Natural Hiſtory*, commends the Uſe of *Nitre*, for the Preſervation of Health in human Bodies; and many ſkilful Botaniſts have given it no leſs a Character for the Preſervation of Vegetables, if its Quantity be rightly proportion'd.

That the Atmoſphere does abound with *ſaline* Particles, is moſt certain; for being fill'd continually with *Effluvia* from Earth and Sea, it muſt needs have from both a great Quantity of *ſaline* Corpuſcles; and theſe will be of different Kinds, according to the Variety of thoſe *Salts* from whence they are derived.

NOLI ME TANGERE. *Vide* Balſamina Mas.

NONSUCH, or FLOWER of BRISTOL. *Vide* Lychnis.

NORTHERN ASPECT, is the leaſt favourable of any in *England*, as having very little Benefit from the Sun, even in the Height of Summer, therefore can be of little Uſe, whatever may have been advanced to the contrary; for altho' many Sorts of Fruit-trees will thrive and produce Fruit in ſuch Poſitions, yet ſuch Fruit can be of little Worth, ſince they are deprived of the kindly Warmth of the Sun to correct their crude Juices, and render them well-taſted and wholeſome: Therefore it is to little purpoſe to plant Fruit-trees againſt ſuch Walls, except it be thoſe which are intended for Baking, *&c.* where the Fire will ripen, and render thoſe Juices wholeſome, which for want of Sun could not be perform'd while growing.

You may alſo plant *Morello Cherries* for preſerving; and *White* and *Red Currants*, to come late, after thoſe which are expoſed to the Sun are gone: And if the Soil be warm and dry, ſome Sorts of Summer Pears will do pretty well on ſuch an Expoſure, and will continue longer in eating, than if they were more expoſed to the Sun. But you ſhould by no means plant Winter Pears in ſuch an Aſpect, as hath been practiſed by many ignorant Perſons; ſince we find, that the beſt South Walls, in ſome Years, are barely warm enough to ripen thoſe Fruits.

NOVEMBER.

Work to be done in the KITCHEN GARDEN.

The Ground between your Artichokes muſt now be trench'd, obſerving to lay a large Ridge of Earth over the Roots, equally on their Sides and Tops, to prevent their being injured by Froſt, which will preſerve them much better than long Dung, which is by ſome ignorant Perſons uſed for that Purpoſe.

Your Aſparagus Beds, which were not dreſſed the laſt Month, ſhould not be deferred any longer than till the Beginning of this; therefore you muſt cut down the Haulm, and hough the Weeds from off the Beds into the Alleys, where they muſt be buried, and the Earth of the Alleys ſhould be ſpread over the Beds.

In mild Weather you muſt let your Cauliflower and Lettuce Plants, which are under Glaſſes or in Frames, have as much free Air as poſſible, by ſetting off the Glaſſes every Day in dry Weather; and in moiſt Weather the Glaſſes ſhould be raiſed to let in Air; for they ſhould not receive too much Wet at this Seaſon, leſt it ſhould cauſe them to rot.

You muſt alſo ſow Peaſe and plant Beans in dry Weather, to ſucceed thoſe which were planted the former Month; and you ſhould draw ſome Earth to the Stems of thoſe which are come up, which will preſerve them from being injured by the Froſt.

Sow all Sorts of Sallet-herbs upon moderate Hot-beds, as Lettuce, Creſſes, Muſtard, Rape, Radiſh, Turnep, *&c.* that the Table may be conſtantly furniſhed with them; and in dry Weather take up your Endive which is full grown, and lay it into Trenches to blanch, obſerving always to place it on the Sides of the Ridges, that the Wet may run off, otherwiſe it would rot the Plants: You muſt alſo earth up your Celery to blanch it, being careful not to bury the Heart of the Plants.

You ſhould now dung and trench the Ground which is deſigned for early Crops, laying it in Ridges until the Time that you make uſe of it, which will be of great Service to refreſh and ſweeten the Ground.

The Beginning of this Month you ſhould ſow ſome Carrots and Radiſhes on warm Borders, near Pales and Hedges, to come early in the Spring, provided you did not perform it the Latter-end of the laſt Month, which if you did, you may defer the doing of it until the Middle of this, whereby you will have a greater Chance of ſucceeding.

Your Spinach, Onions, and other Crops which were ſown in *July* and *Auguſt*, muſt be conſtantly kept clear from Weeds, which, if permitted to remain at this Seaſon, will overſpread the Crops, and by detaining the Moiſture will cauſe them to rot.

Pick all decay'd Leaves from off your Cauliflower Plants, and draw ſome Earth up to the Stems of thoſe which are under Bell or Hand-Glaſſes, being careful that you do not draw the Earth into the Heart of the Plants; for that will deſtroy them.

You may now make Hot-beds for Aſparagus to come in at *Chriſtmas*; but theſe will not produce ſo large nor ſo many Heads as thoſe Beds which are made the Beginning of *January*, nor will the Aſparagus be near ſo well coloured; ſo that it is only fit for Perſons of Curioſity to make Beds at this Seaſon.

Take up the Roots of Carrots, Parſnips, Potatoes, *&c.* toward the End of this Month, and lay them in Sand, in a Place where they may be defended from Froſt and Wet, which are many times injurious to them; and where this is neglected, if the Ground ſhould be frozen up for any Continuance, there will be no Poſſibility of getting the Roots out of the Ground, whereby the Kitchen cannot be ſupplied with theſe Things until the Froſt is out of the Ground again.

If this Month ſhould prove dry and froſty, you muſt carry Dung into the Quarters of the Kitchen-Garden, that it may be ready when you want to dig the Ground, which will forward your Affairs greatly. The not obſerving of this many times cauſes a great Hurry of Buſineſs together, which ſhould be avoided as much as poſſible, becauſe whenever this happens, either ſome Things are intirely neglected, or are ſlighted over too careleſly.

You muſt now freſh tie your Reed-Hedges with Oſiers, otherwiſe the ſtrong Winds, which uſually happen at this Seaſon, will tear them from the Stakes, and break the Reeds, which will render it troubleſome to repair them.

Where there are Hot-beds either for Salleting, Cucumbers, or any other Purpoſe, they muſt be carefully attended at this Seaſon; for the Nights are now long and cold, and the Days either froſty, wet, or foggy, ſo that little Air can be given to the Beds, whereby the Plants do often grow mouldy, and rot off, and the Heat of the Beds is often greatly abated either by Rain or Snow, which renders it very difficult to manage Hot-beds at this Seaſon.

Products of the KITCHEN-GARDEN.

Cabbages, Savoys, Cauliflowers which were ſown in *May*, Brown-cole or Bore-cole, ſome late Artichokes, Red Cabbages, Spinach, Sprouts of Cabbages, Onions, Leeks, Garlick, Rocambole, Shalots, Turneps, Beets, Carrots, Parſnips, Skirrets, Salſafy, Potatoes, Scorzonera, Horſe Radiſh, Jeruſalem Artichokes, *&c.*

For Sallets; Lettuce, Creſſes, Turnep, Muſtard, Corn-Sallet, Coriander, and other ſmall Herbs from the Hot-bed, or warm Borders near Walls; as alſo Endive, Celery, and, if the Seaſon is mild, ſome Brown Dutch and common Cabbage Lettuce.

For Soup; Beets, Chardoons, Thyme, Celery, Winter Savory, Hyſſop, Sorrel, with ſome others.

Work to be done in the FRUIT GARDEN.

If the Seaſon be mild, you may ſtill prune Pear-Trees, Apple-Trees, Vines, and other hardy Kinds of Fruit-Trees, either againſt Walls, Eſpaliers, or Standards; but it is not proper to do it too late in the Month, leſt great Rains and Froſts ſucceeding each other, hurt the Trees when the Wounds are freſh.

You muſt now diveſt your Fig-Trees of all their late Fruit, which, if left on, will rot and infect the tender Branches; and nail the Shoots of the Trees cloſe to the Wall, whereby they will be protected from the Injuries of the Froſt much better than if they were left at a Diſtance from the Wall. You may alſo place ſome Pannels of Reeds before them, if the Froſt be very ſevere, which will preſerve the fruiting Branches from being kill'd, and cauſe the Fruit to come out much earlier the following Spring.

Such Fruit-trees as were planted the former Month for Standards, ſhould be carefully ſtaked, and thoſe againſt Walls or Eſpaliers muſt be faſten'd thereto, to prevent their being diſplaced by the Violence of the Wind, whereby their new Fibres, which have been ſent forth ſince they were planted, would be deſtroy'd, to the great Prejudice of the Trees. You muſt alſo obſerve to lay ſome Mulch upon the Surface of the Ground, about their Roots, (where it has not been done already) to prevent the Froſt from penetrating the Ground to the Roots of the Trees.

The Beginning of this Month you may tranſplant Fruit-trees upon a warm dry Soil, if the Weather is mild; but it would have been better done the former Month, becauſe the Ground being then warm, the Trees do put out Fibres very ſoon after planting, which ſtrengthens them to endure the Cold; whereas thoſe which are late planted rarely take freſh Rooting until the Spring.

Plant Gooſeberries, Raſpberries, Strawberries, and Currants, if the Weather be mild, and dig between the Rows of Gooſeberries and Currants which were formerly planted, to clear the Ground from Weeds; but you ſhould firſt prune the Trees, that there may be no Litter afterwards; and if you want Ground for Kitchen Herbs, you may plant ſome Coleworts for Spring Uſe between them.

Clear your Strawberry-beds from Weeds and Runners, and dig up the Alleys between the Beds, ſpreading a little of the Earth between the Plants upon the Beds, which will greatly ſtrengthen them; but if the Ground be very poor, it will be proper to ſpread a little very rotten Dung over the Beds, which will be very ſerviceable to them.

If you have any late Fruits ſtill remaining upon the Trees, you muſt gather them the firſt dry Day; for if they are ſuffer'd to hang longer upon the Trees, they will be in danger of periſhing by Froſt and Wet: And your fine Winter Pears and Apples, which were gather'd the laſt Month, muſt now be pack'd up cloſe in Baſkets of Wheat-ſtraw, and placed where the Froſt nor too much Air can get to them, otherwiſe they are liable to periſh in a ſhort Time.

Fruits in prime, or yet laſting.

Pears; Sucre-vert, La Chaſſerie, La Marquiſe, Chat Brulé, Le Beſidery, Craſane or Bergamot Craſane, Martin Sec, L'Amadote, Louiſe-bonne, Colmar, Petit Oin, Virgoule, Spaniſh Boncretien, Ambrette, with ſome others.

Apples; Rennette Griſe, Aromatick Pippen, Nonpareil, Golden Pippen, Calville rouge, Calville blanch, Courpendu, Fenouillette, Herefordſhire Pearmain, Holland Pippen, French Pippen, Kentiſh Pippen, Harvey Apple, Pile's Ruſſet, Golden Ruſſet, Wheeler's Ruſſet, Winter Queening, Pear Ruſſet, with ſome others of leſs Note.

Bullace, Cheſnuts, Hazle-nuts, Walnuts, Medlars, Services, Almonds, with ſome late Grapes.

Work to be done in the NURSERY.

If in the former Month you could not finiſh tranſplanting all your Trees in the Nurſery, you may now complete it; but this ſhould be done the Beginning of this Month, that the Fibres may be puſh'd out before Winter; for all ſuch Trees as are planted at the End of this Month, or in the two following Months, do ſeldom put out Roots until the Spring; for the Ground being now render'd cold, Vegetation is at a Stand, till the Warmth of the Spring puts the Juices into Motion again.

You muſt now lay ſome Mulch upon the Surface of the Ground about the Stems of the new-planted Trees, to prevent the Froſt from penetrating to their Roots, which often deſtroys the young Fibres, and greatly weakens the Trees.

Continue to carry Dung into ſuch Parts of your Nurſery as require it, in dry Weather, and ſpread it upon the Surface of the Ground between the Trees, that the Rain in Winter may waſh the Salts into the Ground, before the Ground is dug in Spring.

Where you intend to make new Plantations in the Spring, you ſhould now prepare your Ground, by trenching of it well, and laying it in Ridges, that the Froſt may mellow it.

Faſten all your new-planted Trees with Stakes, *&c.* that the ſtrong Winds of this Seaſon may not diſplace them.

Where you have any Exotick Trees or Shrubs in Pots, you ſhould now plunge the Pots either into the Earth, or ſome old Tan, in a warm Situation, to prevent the Froſt from freezing their Roots, which often is deſtructive to them while they are young.

Work to be done in the FLOWER GARDEN.

The Beginning of this Month you muſt finiſh planting your bulbous-rooted Flowers, which are deſigned for planting before *Chriſtmas*; for if they are ſet late in the Month, there will not be Time enough for them to ſtrike Root before the Froſt comes on, which will prevent them, ſo that they will be in danger of being deſtroy'd.

Your Boxes and Pots of ſeedling bulbous-rooted Flowers muſt now be placed in a warm Situation, where they may enjoy the Sun, and be ſcreen'd from cold Winds.

Cut down the Stalks of ſuch late flowering Plants which now begin to decay, and rake over the Borders of the Pleaſure-Garden, to ſtir the Surface of the Ground, which will prevent Weeds and Moſs from growing thereon; but you ſhould be very careful not to ſtir the Earth too deep, leſt you injure the Roots which are under Ground.

If the Seaſon continues mild, you may yet tranſplant Peonies, Monks-hood, Flag-leav'd Iris's, and moſt other knobbed-rooted Plants, as alſo ſome Lychnis's, Veronica's, Canterbury Bells, London Pride, and other hardy fibroſe-rooted Plants; tho' it were better if done the former Month, becauſe if the Froſt ſhould ſet in ſoon after they are planted, it will prevent their taking Root.

The Beds of ſeedling bulbous-rooted Flowers, which were not removed the laſt Seaſon, ſhould be raked over, to prevent Weeds and Moſs from growing thereon, and ſome freſh Earth ſhould be ſpread over their Surface, to prevent the Froſt from injuring the Roots.

Your Pots of choice Auricula's and Carnations muſt be ſhelter'd from hard Rains, Froſt, and Snow, by Coverings either of Mats or Cloths; but where there is not Conveniency for this, the Pots ſhould be laid down on one Side, to prevent the Moiſture from lodging in the Pots, which often rots them.

You may yet tranſplant Roſes, Lilacs, Syringa's, Jaſmines, Laburnums, Spirea frutex, Honeyſuckles, Hyperium frutex, Colutea's, and moſt other hardy flowering Shrubs, if the Soil be dry where they are to be planted, otherwiſe it is better to defer it till *February*.

Turn your Compoſts which have been prepared for Pots o Borders, that the Parts may be equally mix'd, and may receiv the Benefit of Air and Froſt, to ſweeten them, and rende them looſer. You ſhould alſo prepare freſh Compoſts at thi Seaſon, that you may not want a Supply the following Year it being the better way to have three or four Stocks under eac other, that they may lie the longer before they are uſed; fo if the Parts are not well mixed, the Plants will not thrive we which are planted therein.

Toward the Latter-end of this Month, if the Seaſon ſhoul prove wet or froſty, you muſt arch your Beds of choice Anemonies, Ranunculus's, and Hyacinths, with Hoops, that the may be cover'd with Mats or Cloths, to prevent the Froſt fro penetrating the Ground to the Roots, and keep off too larg Quantities of Water, which, if permitted to ſoak into th Beds, will cauſe the Roots to rot off in the Spring.

Yo

Your Wilderneſs Quarters ſhould now be trimm'd, and the Ground dug between the Trees, which will render it neat, and encourage the Growth of the Trees; but if you have any Flower-roots growing therein, you muſt be careful not to deſtroy them in digging.

In very wet or froſty Weather, when little Work can be done in the Garden, you ſhould prepare your Seeds ready for ſowing in the Spring, and make a Quantity of Numbers to label your choice Flowers; and be ſure to prepare your Tools of all Sorts, that they may be ready for Uſe in the Spring.

Plants in Flower in the open Air.

Some ſorts of Starworts, two ſorts of Golden Rods, Annual Stock-Gilliflower, Double Colchicum, Saffron, Heart's-eaſe or Panſies, three or four ſorts of perennial Sunflowers, Plumbago or Leadwort; and if the Seaſon be mild, ſome Single Anemonies and Polyanthus Narciſſus, where they were not removed the laſt Summer.

Hardy Trees and Shrubs now in Flower.

Arbutus or Strawberry-tree, Lauruſtinus, Muſk Roſe, Paſſion Flower, Clematitis Boœtica, Cytiſſus Lunatus, Geniſta Spinoſa, and Monthly Roſe.

Work to be done in the GREEN-HOUSE *and* STOVE.

The Beginning of this Month you muſt remove into the Green-houſe ſuch hardy Exotick Plants as have been permitted to remain abroad till this Time: and now you ſhould place all your Plants in the Green-houſe into the Order you intend they ſhall remain all the Winter; in doing of which you ſhould obſerve to place the talleſt Plants backward, and to let them ſlope down gradually toward the Front; but do not place them ſo near that their Branches may interfere; for that would greatly injure their Heads.

In mild Weather you ſhould let your hardy Exotick Plants have as much free Air as poſſible, by opening the Glaſſes every Day, and you muſt look over them every Day conſtantly, to ſee which of them want Water; for there are ſome Sorts of Plants which will require to be water'd three or four times in a Week, when many others do not require it above once; ſo that you ſhould not water them all at the ſame Time, but only thoſe which you ſee require it; you ſhould alſo obſerve to do it in a Morning, that the Damp may paſs off before the Windows are cloſe ſhut in the Evening, otherwiſe it will injure your Plants.

You muſt frequently pick off all decayed Leaves from your Plants, and not permit them to fall among your Pots and Tubs, which will make a Litter in the Houſe, and as they rot will infect the Air, which being imbibed by the Plants, will cauſe them to change the Verdure of their Leaves, to a pale ſickly Complexion.

As the Cold advances you muſt increaſe your Fires in the Stoves proportionably, being careful not to over-heat the Air, leſt you cauſe the Plants to ſhoot too freely, which is injurious to them at this Seaſon, nor ſhould you ſuffer the Air to be too cold, leſt their Leaves decay and fall off, and the extreme Parts of the Plants periſh; you muſt alſo obſerve to water the Plants as often as you perceive they require it, which will be proportionable to the Heat of the Air; but the Water ſhould be placed in the Stove eighteen or twenty Hours before it is uſed, that it may acquire a proportionable Heat to the Air of the Houſe; and never give it in too great Quantities; for it is much the better Method, to water your Plants often and ſparingly, than to over-water them at this Seaſon.

You muſt conſtantly pick off all decayed Leaves from the tender Plants in the Stove, and clean their Leaves and Stems from Filth, which they are very ſubject to contract at this Seaſon, as alſo from Inſects, which often infeſt them, eſpecially the Coffee-tree, which will require to be frequently cleaned.

Your Anana or Pine-Apple Plants muſt not be ſuffer'd to remain longer in the Bark-bed than the Beginning of this Month, at which Time they ſhould be removed into the Stove, obſerving to do it in a warm Day, and place them where they may have a great Share of Heat, without which they ſeldom produce Fruit.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

Several ſorts of Aloes, ſome Geraniums, Sedum Arboreſcens, Cotyledons, Anemonoſpermos's, Leonurus, Canary Campanula, Candy-tuft Tree, yellow Indian Jaſmine, Indian Nasturtium with a double Flower, Spaniſh Jaſmine, Viburnums, Ilex-leav'd Jaſmine, Senecio folio retuſo, Large Blue Virginian Starwort, Double-flower'd Myrtle, Caſſia Bahamenſis, Papaw-Tree, Chryſanthemum Arboreſcens, Doria Africana Jacobææ folio, Senſitive Plants, Azorian Jaſmine, Granadilla's, Alcæa Africana Arboreſcens, Guernſey Lily, Belladonna Lily, with ſome others.

NUCIFEROUS TREES, are ſuch which produce *Nuts*.

NUMMULARIA, [takes its Name of *Nummus*, Lat. *Money*, becauſe its Leaves, by their Roundneſs, reſemble Money: It is alſo call'd *Centimorbia*, as tho' it were a Plant that cures an hundred Diſeaſes.] Money-wort, or Herb Two-pence.

This Plant grows wild in ſhady moiſt Places, in divers Parts of *England*; but as it is ſeldom cultivated in Gardens, ſo I ſhall ſay nothing of its Culture in this Place.

NURSERY: There is no ſuch Thing as having a fine Garden or Plantation, without a *Nurſery* both for Trees and Flowers, in which there are continually new Varieties of *Fruits*, *Timber*, or *Flowering Trees*, and choice *Flowers*, raiſed for a Supply of the ſeveral Parts of the *Garden*, *Orchard*, and *Wilderneſs*. The Size of this *Nurſery* muſt be proportion'd to the Extent of your Garden, or deſigned Plantation; ſo that it is impoſſible to be exact in determining the Quantity of Ground neceſſary to be employed in this Way. But for a *Nurſery* of *Fruit*, *Foreſt*, or *Flowering Trees*, there ſhould not be leſs than two or three Acres for a large Garden, but for a ſmall Garden half an Acre will be ſufficient. And for a *Nurſery* for *Flower-roots*, *Plants*, &c. one Acre for a large Garden, and a quarter of an Acre for a ſmall one, will be enough. But this (as I ſaid before) cannot be well limited; ſince ſome Perſons, who are very curious in raiſing vaſt Quantities of new Flowers from Seed, will employ more than three times the Ground that is neceſſary only to raiſe a Supply of Flowers for their Borders, which are either annual, or biennial, and require to be brought up to ſupply the Place of ſuch as have flower'd and decayed. But I ſhall firſt take Notice of the Method for raiſing a *Nurſery* of *Fruit* or *Foreſt Trees*: in doing of which, you ſhould obſerve,

1. That the Soil in which you make the *Nurſery* be not better than that where the Trees are to be planted out for good: The not obſerving this, is the Reaſon that Trees are often at a ſtand, or make but little Progreſs for three or four Years, after they come from the *Nurſery*; as it commonly happens to ſuch Trees as are raiſed near *London*, and carried into the Northern Parts of *England*, where being planted in a poor Soil, and a much colder Situation, their Fruits ſeldom ripen well: Therefore it is by far the better Method (when you have obtained the Sorts you would propagate) to raiſe a *Nurſery* of the ſeveral Sorts of Stocks proper for the various Kinds of Fruit, upon which you may bud or graft them; and thoſe Trees which are thus raiſed upon the Soil, and in the ſame Degree of Warmth where they are to be planted, will ſucceed much better than thoſe brought from a greater Diſtance, and from a richer Soil.

2. This Ground ought to be freſh, and not ſuch as has been already worn out by Trees, or other large-growing Plants; for in ſuch Soil your Stocks will not make any Progreſs.

3. It ought not to be too wet, nor over-dry, but rather of a middling Nature; tho' of the two Extremes, dry is to be preferr'd: Becauſe in ſuch Soils (tho' the Trees do not make ſo great a Progreſs as in moiſt, yet) they are generally ſounder, and more diſpoſed to Fruitfulneſs.

4. You muſt alſo obſerve to incloſe it, that Cattle and Vermin may not come in; for theſe will make ſad Havock with young Trees, eſpecially in Winter, when the Ground is cover'd with Snow, that they have little other Food which they can come at: Some of the moſt miſchievous of theſe Animals are *Hares* and *Rabbits*, which are great Deſtroyers of young Trees at that Seaſon, by eating off all their Bark; therefore you muſt carefully guard your *Nurſery* againſt theſe Enemies.

The Ground being incloſed, ſhould be carefully trench'd about eighteen Inches or two Feet deep, provided it will allow it; this ſhould be done in *Auguſt*, that it may be ready to receive young Stocks at the Seaſon for Planting, which is commonly at the Beginning of *October*. In trenching of the Ground, you muſt be very careful to cleanſe it from the Roots of all noxious Weeds, ſuch as *Couch-graſs*, *Docks*, &c. which, if left in the Ground, will get in amongſt the Roots of the Trees, ſo as not to be gotten out afterwards, and will ſpread and over-run the Ground, to the great Prejudice of your young Stocks.

After having dug the Ground, and the Seaſon being come for planting, you muſt level down the Trenches as equal as poſſible; and then lay out the Ground into Quarters, proportionable to the Size thereof; and thoſe Quarters may be afterwards laid out in Beds, for the ſowing of Seeds, or the Stones of Fruit.

The beſt Sort of Stocks for *Peaches*, *Nectarines*, &c. are ſuch as are raiſed from the Stones of the *Muſcle* and *White Pear Plum*: but you ſhould never plant Suckers of theſe, (which is what ſome People practiſe;) for thoſe ſeldom make ſo good Stocks, nor are ever well-rooted Plants: beſides, they are very ſubject to produce great Quantities of Suckers from their Roots, which are very troubleſome in the Borders or Walks of a Garden, and do greatly injure the Tree; ſo that you ſhould annually, or at leaſt every other Year, ſow a few other Stones, that you may never be at a Loſs for Stocks.

For *Pears*, you ſhould have ſuch Stocks as have been raiſed from the Kernels of the Fruit where *Perry* hath been made; or elſe preſerve the Seeds of ſome Sorts of Summer *Pears*, which do generally ſhoot ſtrong and vigorous, as the *Cuiſs Madam*, *Windſor*, &c. which you ſhould ſow for Stocks, early in the Spring, upon a Bed of good light freſh Earth, where they will come up in about ſix Weeks, and, if kept clear from Weeds, will be ſtrong enough to tranſplant out the *October* following. But for many Sorts of Summer and Autumn *Pears*, *Quince* Stocks are preferable to free (*i. e. Pear*) Stocks; theſe are very often propagated from Suckers, which are generally produced in Plenty from the Roots of old Trees: but thoſe are not near ſo good as ſuch as are propagated from Cuttings, which have always much better Roots, and are not ſo ſubject to produce Suckers as the other; which is a very deſirable Quality; ſince theſe Suckers do not only rob the Trees of Part of their Nouriſhment, but are very troubleſome in a Garden.

Apples are grafted or budded upon Stocks raiſed from Seeds which come from the *Cyder-Preſs*, or upon *Crab* Stocks; the latter of which are eſteem'd for their Durableneſs, eſpecially for large Standard Trees; theſe ſhould be raiſed from Seeds, as the *Pear* Stocks, and muſt be treated in the ſame Manner; for thoſe procured from Suckers, *&c.* are not near ſo good: but for ſmall Gardens, the *Paradiſe* Stock hath been of late greatly eſteem'd; it being of very humble Growth, cauſeth the Fruit-Trees grafted or budded thereon to bear very ſoon, and they may be kept in ſmall Compaſs: but theſe are only proper for very ſmall Gardens, or by way of Curioſity; ſince the Trees thus raiſed are but of ſhort Duration, and ſeldom ariſe to any Size to produce Fruit in Quantities, unleſs the Graft or Bud be buried in Planting, ſo that they put forth Roots, and then they will be equal to Trees grafted upon free Stocks, ſince they receive but ſmall Advantage from the Stock.

For *Cherries*, you ſhould make uſe of Stocks raiſed from the Stones of the common *Black* or the wild *Honey Cherry*, both of which are ſtrong free Growers, and produce the cleaneſt Stocks.

For *Plums*, you may uſe the Stones of moſt free-growing Sorts; which will alſo do very well for *Apricocks*, theſe being not ſo difficult to take as *Peaches* or *Nectarines*: but (as I ſaid before) theſe ſhould not be raiſed from Suckers, for the Reaſon there aſſigned, but rather from Stones.

There are ſome Perſons who recommend the *Almond* Stock for ſeveral Sorts of tender *Peaches*, upon which they will take much better than upon *Plum* Stocks: but theſe being tender in their Roots, and apt to ſhoot early in the Spring, are by many People rejected: and I think, if ſuch tender Sorts of *Peaches* which will not take upon *Plum* Stocks, were budded upon *Apricocks*, they would take very well; as would all Sorts of *Peaches* which are planted upon dry Soils, continue much longer, and not to be ſo ſubject to Blight, if they were upon *Apricocks*; for it is obſerved, that upon ſuch Soils where *Peaches* ſeldom do well, *Apricocks* will thrive exceedingly; which may be owing to the Strength and Compactneſs of the Veſſels in the *Apricocks*, which render it more capable of aſſimilating or drawing its Nouriſhment from the *Plum* Stock, which in dry Soils ſeldom afford it in great Plenty to the Bud; and the *Peach*-Tree being of a looſe ſpungy Nature, is not ſo capable to draw its Nouriſhment therefrom, which occaſions that Weakneſs which is commonly obſerved in thoſe Trees when planted on a dry Soil.

There are ſome People who of late have budded and grafted *Cherries* upon Stocks of the *Corniſh Cherry*, which, they ſay, will render the Trees more fruitful, and leſs luxuriant in Growth, ſo that they may be kept in leſs Compaſs; theſe Stocks having the ſame Effect upon *Cherries*, as the *Paradiſe* Stock hath on *Apples*.

Having provided yourſelf with young Stocks of all theſe different Sorts, which ſhould be raiſed in the Seminary the preceding Year, you ſhould proceed to tranſplanting of them in *October* (as was before directed) into the *Nurſery*. The Diſtance which they ſhould be planted, if deſigned for Standards, ſhould be three Feet and an half, or four Feet, Row from Row, and a Foot and an half diſtant in the Rows; but if for Dwarfs, three Feet Row from Row, and one Foot in the Rows, will be a ſufficient Diſtance.

In taking theſe Stocks out of the Seed-beds, you muſt raiſe the Ground with a Spade, in order to preſerve the Roots as intire as poſſible; then with your Knife you ſhould prune off all the very ſmall Fibres; and if there are any which have a Tendency to root down-right, ſuch Roots ſhould be ſhortened: then having thus prepared the Plants, you ſhould draw a Line acroſs the Ground intended to be planted, and with your Spade open a Trench thereby exactly ſtrait, into which you ſhould place them at the Diſtance before deſigned, ſetting them exactly upright; and then put the Earth in cloſe to them, filling up the Trench, and with your Foot preſs the Earth gently to the Roots of them, obſerving not to diſplace them ſo as to make the Rows crooked, which will render them unſightly. Theſe Plants ſhould by no means be headed, or pruned at Top, which will weaken them, and cauſe them to produce lateral Branches, and thereby ſpoil them.

If the Winter ſhould prove very cold, it will be of great Service to your young Stocks, to lay ſome Mulch upon the Surface of the Ground near their Roots, which will prevent the Froſt from penetrating the Ground ſo as to hurt the tender Fibres which were produced after planting: but you ſhould be careful not to let it lie too thick near the Stems of the Plants, leſt the Moiſture of the Dung ſhould hinder the tender Bark, which it often does where there is not due Care taken to prevent it.

In the Summer Seaſon, you muſt always obſerve to hough and deſtroy the Weeds; which, if permitted to remain in the *Nurſery*, will greatly weaken and retard the Growth of your Stocks: and the ſucceeding Years, you ſhould obſerve to dig up the Ground every Spring between the Rows, which will looſen it ſo, as that the Fibres may eaſily ſtrike out on each Side, and the Weeds will be thereby deſtroyed: you ſhould alſo obſerve, where any of the Stocks have ſhot out lateral Branches, to prune them off, that they may be encouraged to grow upright and ſmooth.

The ſecond Year after planting, ſuch of the Stocks as are deſigned for Dwarf-trees, will be fit to bud; but thoſe which are deſigned for Standards, ſhould be ſuffer'd to grow five or ſix Feet high before they are budded or grafted. The Manner of Budding and Grafting being fully deſcribed under their reſpective Heads, I ſhall not repeat them in this Place; nor need I ſay any thing more of treating theſe Trees after budding, that being alſo treated of under the ſeveral Articles of Fruits; I ſhall only add, that thoſe Stocks which were budded in the Summer, and have failed, may be grafted the following Spring; but *Peaches* and *Nectarines* ſeldom take well from Grafts; theſe ſhould therefore be always budded.

The *Nurſery* deſigned for *Foreſt-Trees* and *Flowering-Shrubs* ſhould be larger than that for *Fruit-Trees*, eſpecially if you intend to make large Plantations of theſe Trees: but in planting of theſe, you ſhould always obſerve to place the large growing Kinds by themſelves, ſeparate from thoſe of lower Growth, otherwiſe the large Trees will overſhade and ſtarve the ſmaller. But as the Method of propagating all the different Sorts of theſe Trees, whether from Seeds, Cuttings, or Layers, is ſet down under their ſeveral Articles, ſo it is needleſs to repeat it in this Place.

I ſhall therefore only add, that after you have drawn off the Trees from any Part of your *Nurſery*, you ſhould, for a Year or two, employ the Ground for Kitchen-Garden, or ſome other Summer Crops, in order to refreſh it, before you plant it again with Trees; and you ſhould always obſerve to put different Sorts of Trees upon the Ground from thoſe which grew in the ſame Place before, otherwiſe they ſeldom thrive well.

The Ground you intend for the *Flower-Nurſery*, ſhould be well ſituated to the Sun, but defended from ſtrong Winds by Plantations of Trees or Buildings, and the Soil ſhould be light and dry, which muſt always be obſerved, eſpecially for bulbous-rooted Flowers, which are deſigned to be planted therein: the Particulars of which are exhibited under the Articles of *Flowers*.

In this *Nurſery* ſhould be planted the Off-ſets of all your bulbous-rooted Flowers, where they are to remain until they become blowing Roots; when they ſhould be removed into the Pleaſure-Garden, and planted either in Beds or Borders, according to the Goodneſs of the Flowers, or the Management which they require.

You may alſo, in this Ground, raiſe the ſeveral Sorts of bulbous rooted Flowers from Seed, by which means new Varieties may be obtained: but moſt People are diſcouraged from ſetting about this Work, from the Length of Time before the Seedlings will come to flower; however, after a Perſon hath once begun, and conſtantly continued ſowing every Year, after the Parcel firſt ſown has flower'd, the regular Succeſſion of them coming annually to flower, will not render this Method ſo tedious as it at firſt appear'd.

The Seedling *Auricula's*, *Polyanthus's*, *Ranunculus's*, *Anemonies*, *Carnations*, &c. ſhould be raiſed in this *Nurſery*, where they ſhould be preſerved until they have flower'd; when you ſhould mark all ſuch as are worthy of being tranſplanted into the Flower-Garden; which ſhould be done in their proper Seaſons: for it is not ſo well to have all theſe ſeedling Flowers expoſed to publick View in the Flower-Garden, becauſe it always happens, that there are great numbers of ordinary Flowers produced amongſt them, which will make but an indifferent Appearance in the Pleaſure-Garden.

In this Place alſo ſhould be raiſed all the Sorts of Biennial or Perennial Flowers from Seeds, to ſupply the Borders of the Pleaſure-Garden as the old Roots decay; ſuch as *Stock-Gilliflowers*, *Canterbury-Bells*, *Fox-Gloves*, *French Honeyſuckles*, *Wall-flowers*, *Columbines*, *Hollyhocks*, *Campanula's*, and many other Sorts, which are all under their reſpective Articles treated of, with the Method of propagating each Kind: I ſhall therefore only add, that the Earth in this *Nurſery* ſhould be often changed, and freſh brought in; as alſo the ſeveral Sorts of Flowers which are there raiſed, ſhould be every Year ſhifted into different Places, and not the ſame Sorts raiſed two or three Years upon the ſame Spot of Ground, for the Reaſon before aſſigned.

NUX AVELLANA. *Vide* Corylus.

NUX JUGLANS, [of *Nux*, a *Nut*, and *Juglans*, as tho' *Jovis Glandis*; i. e. *Jupiter's Acorn*] The Wallnut.

The *Characters* are;

It hath Male Flowers (or Katkins) which are produced at remote Diſtances from the Fruit on the ſame Tree: the outer Cover of the Fruit is very thick and green, under which is a rough hard Shell, in which the Fruit is incloſed, ſurrounded with a thin Skin: the Kernel is deeply divided into four Lobes: and the Leaves of the Tree are pinnated, or winged.

The *Species* are;

1. Nux Juglans, *ſive Regia vulgaris.* *C. B. P.* The common Walnut.
2. Nux Juglans *fructu maximo.* *C. B. P.* The large French Walnut.
3. Nux Juglans *fructu tenero, & fragili putamine.* *C. B. P.* The thin-ſhell'd Walnut.
4. Nux Juglans *bifera.* *C. B. P.* The double Walnut.
5. Nux Juglans *fructu ſerotino.* *C. B. P.* The late-ripe Walnut.
6. Nux Juglans *fructu perduro.* *Tourn.* The hard-ſhell'd Walnut.
7. Nux Juglans *Virginiana nigra.* *H. L.* The Virginian black Walnut.
8. Nux Juglans *Virginiana, nigra, fructu oblongo, profundiſſime inſculpto.* *Rand.* Virginian black Walnut, with a long furrow'd Fruit.
9. Nux Juglans *Virginiana, foliis vulgari ſimilis, fructu ſubrotundo, cortice duriore lævi.* *Pluk. Alm.* The Hickery *or* White Virginian Walnut.
10. Nux Juglans *Virginiana, alba, minor, fructu nucis moſchatæ ſimilis, cortice glabro, ſummo faſtigio, veluti in aculeum producto.* *Pluk. Phyt.* The ſmall Hickery *or* White Virginian Walnut.

The ſix Sorts firſt mention'd are propagated promiſcuouſly in *England*, and I believe are all ſeminal Variations, and not diſtinct Species, as in moſt other Sorts of Fruit-trees; for it rarely happens, that the Trees raiſed from Seeds produce the ſame Sort of Fruit again: ſo that thoſe who would be ſure of their Fruit, ſhould either make Choice of ſuch Trees in the Nurſery which have produced Fruit, and do prove to be the Sort they would have, or elſe inarch the Sorts intended upon any common Walnut-ſtock; in which Method they will ſucceed; but theſe ſeldom make ſo good Trees, as thoſe which are raiſed from Seeds.

The ſecond and third Sorts are chiefly preferr'd for their Fruit, which are very large; and the Shells of the third Sort are ſo tender, as to be broken between the Fingers without any Difficulty; for which Reaſon it is eſteem'd the beſt worth propagating, for the Fruit, of any of the Sorts.

The *Virginian* Sorts are preſerved as Rarities, by ſuch Perſons who are curious in collecting the ſeveral Sorts of Trees; but theſe are all worth cultivating for their Timber, which is preferable to that of our common Walnuts, and theſe Trees are equally as hardy, and ſome of them of much quicker Growth than the common Sort, eſpecially the ſeventh and eighth Sorts; the latter of which produces great Quantities of Fruit annually in the Phyſick-Garden, but they are of no Uſe, except to propagate the Species; for their Shells are ſo hard as ſcarcely to be broken with a Mallet, and the Kernel is ſo ſmall that it is not worth the Trouble of coming at it.

All the Sorts of Walnuts which are propagated for Timber, ſhould be ſown in the Places where they are to remain; for the Roots of theſe Trees do always incline downward; which being ſtopp'd or broken, do prevent their aſpiring upward, ſo that they afterwards divaricate into Branches, and become low ſpreading Trees: but ſuch as are propagated for Fruit, are greatly mended by tranſplanting; for hereby they are render'd more fruitful, and their Fruit are generally larger and fairer: it being a common Obſervation, That down-right Roots do greatly encourage the luxuriant Growth of Timber in all Sorts of Trees; but ſuch Trees as have their Roots ſpreading near the Surface of the Ground, are always the moſt fruitful.

The Nuts ſhould be preſerved in their outer Covers in dry Sand until *February*; when they ſhould be planted in Lines, at the Diſtance you intend them to remain; but in the Rows they may be placed pretty cloſe, for fear the Nuts ſhould miſcarry; and the young Trees, where they are too thick, may be removed, after they have grown three or four Years, leaving the Remainder at the Diſtance where they are to ſtand.

In tranſplanting theſe Trees, you ſhould always obſerve, never to prune either their Roots or Branches, both which are very injurious to them; nor ſhould you be too buſy in lopping or pruning the Branches of theſe Trees; for it often cauſes them to decay: but when there is a Neceſſity of cutting any of their Branches off, it ſhould be done early in *September*, that the Wound may heal over before the Cold increaſes, and the Branches ſhould always be cut off quite cloſe to the Trunk, otherwiſe the Stump which is left will decay, and rot the Body of the Tree.

The beſt Seaſon for tranſplanting theſe Trees, is ſo ſoon as the Leaves begin to decay; at which time, if they are carefully taken up, and their Branches preſerved intire, there will be little Danger of their ſucceeding, altho' they are eight or ten Years old, as I have ſeveral times experienced.

This Tree delights in a firm rich loamy Soil, or ſuch as is inclinable to Chalk or Marle, and will thrive very well in ſtony Ground, and on chalky Hills, as may be ſeen by thoſe large Plantations near *Leatherhead*, *Godſtone*, and *Carſhalton* in *Surrey*, where are great numbers of theſe Trees planted upon the *Downs*, which annually produce great Quantities of Fruit, to the great Advantage of their Owners; one of which, I have been told, farms the Fruit of his Trees, to thoſe who ſupply the Markets, for Thirty Pounds *per Annum*.

The Diſtance theſe Trees ſhould be placed, ought not to be leſs than forty Feet, eſpecially if regard be had to their Fruit; tho' when they are only deſigned for Timber, if they ſtand near, it promotes their upright Growth. The Black *Virginian Walnut* is much more inclinable to grow upright than the common Sort, and the Wood being generally of a more beautiful Grain, renders it preferable to that, and better worth cultivating. I have ſeen ſome of this Wood which hath been beautifully vein'd with Black and White, which, when poliſh'd, has appear'd at a Diſtance like vein'd Marble. This Wood is greatly eſteem'd by the Cabinet-makers for Inlaying, as alſo for Bedſteads, Stools, Tables, and Cabinets, and is one of the moſt durable Woods for thoſe Purpoſes yet known, it being rarely infected with Inſects of any Kind, (which may proceed from its extraordinary Bitterneſs:) but it is not proper for Buildings of Strength, it being of a very brittle Nature, and mighty ſubject to break very ſhort, tho' it commonly gives Notice thereof, by its Crackling ſome Time before it breaks.

The general Opinion, That the beating of this Fruit improves the Trees, I do not believe, ſince in the doing of this, the younger Branches are generally broken and deſtroy'd: But as it would be exceeding troubleſome to gather it by Hand, ſo in beating it off, great Care ſhould be taken that it be not done with Violence, for the Reaſon before aſſigned. In order to preſerve the Fruit, it ſhould remain upon the Trees till it is thorough ripe; when it ſhould be beaten down, and laid in Heaps for two or three Days; after which they ſhould be ſpread abroad, when, in a little Time, their Huſks will eaſily part from the Shells: Then you muſt dry them well in the Sun, and lay them up in a dry Place, where Mice or other Vermin cannot come to them: In which Place they will remain good for four or five Months.

NUX VESICARIA. *Vide* Staphylodendron.

NYMPHÆA, [is ſo call'd, becauſe it grows in Water, which the Poets feign to be the Reſidence of the *Nymphs*] The Water-Lily.

The *Characters* are;

The Flower conſiſts of ſeveral Leaves, which expand in form of a Roſe; *out of the Flower-cup ariſes the Pointal, which afterwards becomes an almoſt globular Fruit, conſiſting of many Cells fill'd with Seeds, which are for the moſt part oblong.*

The *Species* are;

1. NYMPHÆA *alba major.* *C. B. P.* The great White Water-Lily.
2. NYMPHÆA *lutea major.* *C. B. P.* The great yellow Water-Lily.
3. NYMPHÆA *lutea minor, flore fimbriato.* *J. B.* The leſſer yellow Water-Lily, with a fringed Flower.

There are ſome other Species of this Plant, all of which are Natives of deep ſtanding Waters, and therefore not to be cultivated in any other Places.

The beſt Method to propagate theſe Plants, is, to procure ſome of their Seed-veſſels juſt as they are ripe, and ready to open: Theſe ſhould be thrown into Canals, or large Ditches of ſtanding Water, where the Seeds will ſink to the Bottom; and the following Spring the Plants will appear floating upon the Surface of the Water, and in *June* and *July* will produce their beautiful large Flowers: When they are once fix'd to the Place, they will multiply exceedingly, ſo as to cover the whole Surface of the Water in a few Years.

In ſome ſmall Gardens I have ſeen theſe Plants cultivated in large Troughs of Water, where they have flouriſh'd very well, and have annually produced great Quantities of Flowers: But as the Expence of theſe Troughs is pretty great, (their Inſides requiring to be lined with Lead, to preſerve them) ſo there are few People who care to be at that Charge.

O A

OAK. *Vide* Quercus.

OBELISCOTHECA; Dwarf *American* Sun-flower, *vulgo.*

The *Characters* are;

It hath radiated Flowers, having many Florets, which are fertile, but the half Florets are barren: The Placenta is commonly conical, and filled with chaffy Empalements, which appear folded up; in each of which is an Ovary, which is ſhaped like an Obeliſk reverſed, having a hollow Baſe. Theſe Parts are contained in one common Flower-cup, which is deeply cut into ſeveral Segments, and expands in form of a Star: To which may be added, The Leaves are placed alternately.

The *Species* are;

1. OBELISCOTHECA *integrifolia, radio aureo, umbone atro-rubente. Horth. Elth.* Dwarf Sun-flower, with intire Leaves, the Rays of the Flower of a Gold Colour, and a dark red Diſk.
2. OBELISCOTHECA *doronici folio, radio purpureo, umbone atro-rubente.* Dwarf Sun-flower, with Leaves like Leopards-bane, the Rays of the Flower purple, and a dark red Diſk.

Theſe Plants are both Natives of *America*; the firſt of them was brought from *Virginia*, and the other from *Carolina*. They may both be propagated by parting of their Roots in the Spring, planting the Heads into Pots filled with freſh rich Earth, placing them in an open Situation, where they may have the Benefit of Sun and Showers, in which Place they may remain during the Summer-ſeaſon; but in Winter they muſt be ſheltered under a Frame, to protect them from ſevere Froſt, obſerving to let them have as much free Air as poſſible in mild Weather. They muſt be frequently refreſhed with Water, eſpecially in Summer, when it ſhould be given them in Plenty; but in Winter they muſt have it more ſparingly. The firſt Sort increaſes pretty faſt in *England*; whereby it is become pretty common, and is preſerved for the ſake of its Flowers, which are produced in Plenty, and are of long Duration, each Flower continuing in Beauty five or ſix Weeks; and theſe being ſucceeded by new Flowers, the Plants are commonly furniſhed with them four or five Months.

The ſecond Sort is leſs common than the firſt, by reaſon of the few Off-ſets it produces from the Side; and the Seeds rarely being perfected in *Europe*, the Plants cannot be greatly increaſed; therefore, if a Perſon could procure the Seeds of this Plant from *Carolina*, it would be the ſureſt Method to obtain a Stock of the Plants. The Seeds of both theſe Plants ſhould be ſown on a moderate Hot-bed; and when the Plants are grown tolerably ſtrong, they ſhould be each planted into a ſeparate Pot, and inured to the open Air by degrees; after which they muſt be treated as hath been directed for the old Plants.

OCHRUS, Winged Pea.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterward becomes a Pod, for the moſt part round and cylindrical, filled with roundiſh Seeds. To theſe Notes muſt be added, That the Leaves are ſometimes ſimple, and ſometimes conjugated, ending in Tendrils.

The *Species* are;

1. OCHRUS *folio integro, capreolos emittente, ſemine ſubluteo.* *C. B. P.* Ochrus or Winged Pea, with an intire Leaf, ſending forth Tendrils, and a yellowiſh Seed.
2. OCHRUS *folio integro, capreolos emittente, ſemine pullo.* *C. B. P.* Ochrus or Winged Pea, with an intire Leaf, ſending forth Tendrils, and a brown Seed.
3. OCHRUS *folio integro, capreolos emittente, ſemine atro.* *C. B. P.* Ochrus or Winged Pea, with an intire Leaf, ſending forth Tendrils, and a black Seed.
4. OCHRUS *folio diviſo in capreolos abeunte.* *Inſt. R. H.* Ochrus or Winged Pea, with a divided Leaf ending in Tendrils.
5. OCHRUS *Americanus tomentoſus, floribus luteis.* *Plum.* Woolly Ochrus or Winged Pea of *America*, with yellow Flowers.

The three firſt Sorts are accidental Varieties, which differ in the Colour of their Flowers and Seeds, but in every other reſpect are the ſame, ſo that they may be deemed only ſeminal Variations. They are annual Plants, which muſt be ſown in the Spring of the Year, on an open Border or Bed of light freſh Earth, allowing them the ſame Diſtance, as is uſual for the middle Sort of Peaſe. So the better Way is to ſow them in Drills about two Feet aſunder; and when the Plants are come up, the Earth ſhould be drawn to them, in the ſame Manner as is practiſed for Peaſe: And when the Plants begin to riſe in Height, there ſhould be ſome Sticks put down by them, to which they will faſten their Tendrils, whereby they will be ſupported from trailing on the Ground, for want of which, in bad Seaſons, they do not ripen their Seeds kindly. The Ground between the Rows ſhould always be kept clean from Weeds, which, if permitted to grow, will ſoon overbear the Plants, and deſtroy them. About the Middle of *June*, the Plants will flower, and their Seeds will ripen the Beginning of *Auguſt*.

Theſe Plants grow wild in *Lombardy*, and in ſome Parts of *Spain*; but in *England* they are preſerved in the Gardens of ſome Perſons who are curious in Botany, for the ſake of Variety. The Seeds of theſe have been eaten in Times when there has been a Scarcity of other Proviſion, by the poor Inhabitants where they naturally grow; but they are bitter, and hard of Digeſtion, and do not afford good Nouriſhment.

The fourth Sort was diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the Royal Garden at *Paris*, where it flouriſhed, and has ſince been diſtributed to ſeveral Perſons who are curious in collecting of Plants. This is as hardy as the common Sort, ſo may be ſown and treated after the ſame Manner.

The fifth Sort was diſcovered by Father *Plumier* in *America*, and ſince by the late Dr. *William Houſtoun* at *Campechy*. The Seeds of this Sort muſt be ſown on a Hot-bed early in the Spring, and when the Plants come up, they ſhould be tranſplanted each into a ſeparate Pot, and plunged into a moderate Hot-bed; where they ſhould have a large Share of free Air in warm Weather, and muſt be frequently refreſhed with Water. About the Beginning of *July* theſe Plants will flower, and their Seeds will ripen in Autumn.

OCTOBER.

The Weather in this Month is often very favourable, which gives a great Opportunity to the Gardener for planting of Trees, and putting in his Flower-Roots for the ſucceeding Spring: But ſometimes it happens that the Froſt ſets in early in this Month, which occaſions a great deal of Trouble to get his tender Plants ſhelter'd, and his Winter Fruits gather'd, and laid up for Uſe; ſo that, in all theſe Particulars, the Gardener muſt be directed by the Difference of the Seaſons.

Work to be done in the KITCHEN GARDEN.

If your Aſparagus Beds were not dreſs'd in the former Month, they ſhould now be done, by cutting down the wither'd Haulm, and houghing the Weeds from off the Beds into the Alleys, then dig the Alleys, and caſt the Earth over the Beds, burying the Weeds in the Alleys; but where the Beds want manuring, you ſhould ſpread ſome very rotten Dung over them after the Weeds are clean'd off, and then ſpread the Earth of the Alleys thereon.

In dry Weather you ſhould continue to earth up Celery and Chardoons, to blanch them; and draw up ſome Endive, which is full grown, to plant down on the Sides of the Ridges to blanch, becauſe the Cold at this Seaſon increaſing, will injure it, where it remains above Ground tied up to blanch, as was directed in the former Months.

Tranſplant your brown Dutch and common Cabbage Lettuces upon warm Borders, near Walls, Pales, or Hedges, to abide the Winter; as you may alſo ſome Cos, Sileſia, and Imperial Lettuces; but it will be proper to plant theſe Sorts upon Beds, to be cover'd with Frames or Mats in Winter, becauſe if the Froſt ſhould be very ſevere, it will deſtroy theſe Sorts, where they are expoſed to the open Air.

Your Spinach, Carrots, Onions, *&c.* which were ſown the End of *July*, or in *Auguſt*, muſt now be kept clean from Weeds; for if they are permitted to grow, they will over-run and ſpoil your Crops, eſpecially the Spinach, which will rot off where-ever the Weeds ſpread over it.

Plant Beans, and ſow Peaſe upon dry Grounds, and in warm Situations, which ſhould be repeated twice this Month; the firſt at the Beginning, and the other at the End of this Month, becauſe if the firſt ſhould be too forward to ſtand the Winter, the other, being later ſown, may ſucceed.

About the Middle of this Month you ſhould tranſplant your Cauliflower Plants into the Places where they are to abide the Winter: ſome of which ſhould be put under Bell or Hand-Glaſſes, if you have any, obſerving to plant two Plants under each Glaſs; becauſe if one of them ſhould fail, the other will be ſufficient; for in the Spring, if they both live thro' the Winter, one Plant muſt be tranſplanted out. Theſe Plants which are put under Glaſſes, will come earlier than thoſe which are winter'd in Beds, and tranſplanted out in the Spring.

Your Cabbage Plants which were ſown in the Beginning of *Auguſt*, ſhould now be tranſplanted out for good, (eſpecially thoſe of the early *Batterſea* Kind;) but it will be proper to have ſome Plants in a warm Situation reſerved, leſt the Froſt ſhould deſtroy thoſe which are planted out for good. As to the long-ſided Cabbage, which is a later Sort, that need not be planted out for good till *February*.

If you have ſown any Beds of Welſh Onions, you ſhould clean them from Weeds; for at this Seaſon their Blades will intirely decay, ſo that many Perſons have ſuppoſed the Onions were dead; but in ſix Weeks or two Months after, they come up again very ſtrong, and will reſiſt the ſevereſt Froſt; ſo that when all the common Sort of Onions is deſtroy'd by the Cold, theſe will remain, which was the Occaſion of their being ſo much propagated in the Gardens near *London* ſome Years ſince; but their ſtrong Flavour renders them leſs eſteem'd at preſent.

You muſt now ſow all Sorts of Sallet-herbs upon moderate Hot-beds, either under Frames, or arch'd over with Hoops, where they may be cover'd with Mats or Cloths, to protect them from Froſt, otherwiſe they will be deſtroy'd thereby, as ſoon as they appear above Ground. But if you have many Bell or Hand-Glaſſes, you may ſow theſe Seeds under them, notwithſtanding the two Cauliflower Plants which are under each Glaſs; for if the Seeds are not ſown too near the Stems of the Plants, or the Salletting be not ſuffer'd to remain too long about them, it will not injure them; this being conſtantly practiſed by the Gardeners near *London* with good Succeſs.

Some of your Colewort Plants which were late ſown, ſhould now be planted out where they are to remain for Spring Uſe, that they may ſucceed thoſe which were planted out the former Month.

Your Cauliflowers which were ſown in *May* will now begin to ſhew their Heads; therefore you muſt diligently look over them two or three Times a Week, to break down ſome of the inner Leaves upon them, which will protect them from the Froſt or Wet, both which, as alſo their being expoſed to the Sun, will change their Colour, and cauſe them to be unſightly.

The Stems of your Broccoli Plants ſhould now be earth'd up, to protect them from Froſt; but you muſt be careful that the Earth be not drawn into the Hearts of the Plants; for that will deſtroy them.

Toward the End of this Month you ſhould cut down the Roots of your Artichokes cloſe to the Surface of the Earth, and trench the Ground between them, obſerving to lay a good Ridge of Earth over each Row of Plants, to protect them from Froſt; but by no means lay any new Dung about them, as is by ſome unſkilful Perſons too often practiſed, which renders the Plants hard and woody in the Spring, and cauſes them to produce ſmall and ill-nouriſh'd Heads; but where the Ground wants Amendment, you ſhould bury ſome very rotten Dung between the Rows when you trench the Ground, which will greatly ſtrengthen your Plants.

You may now ſow ſome Radiſhes upon warm Borders to come early in the Spring, and if you mix ſome Carrot-ſeed with the Radiſh-ſeed, if the Radiſhes ſhould be deſtroy'd, the Carrots may ſtand, and come early in *May*.

Make ſome moderate Hot-beds to plant Mint and Tanſey upon, that you may have both Sorts for Uſe ſoon after *Chriſtmas*, when they are often required at the Table; and theſe Beds will continue to produce until thoſe in the open Air come in.

You may alſo make Hot-beds for Aſparagus, which will come in *December*; but it is better to ſtay until *December* or *January*; for the Aſparagus will not be near ſo large nor well-colour'd, which is produced in the Middle of Winter, when there is little Sun, as thoſe which come in *February*.

Products of the KITCHEN GARDEN.

Cabbages, Savoys, late Cauliflowers, ſome Artichokes, Carrots, Parſnips, Turneps, Onions, Leeks, Potatoes, Rocambole, Shallots, Beets, Skirrets, Scorzonera, Salſafy, Celery, Endive, Chardoons, Chervil, Corn-ſallet, Rape, Radiſh, Muſtard, Creſſes, Lettuce, and all ſorts of young Sallet-herbs; and on warm Borders ſome Cabbage Lettuce, Spinach, Coleworts, Borecole, Muſhrooms, Sprouts, with Sage, Roſemary, Thyme, Winter Savory, and many other Aromatick Plants.

Work to be done in the FRUIT GARDEN.

The Beginning of this Month you may prune Peach-Trees, Nectarines, Apricocks, and Vines, which is a much better Time than to ſtay until the Spring, as is the common Practice; for if this Work be perform'd early in Autumn, the Wounds will heal over before hard Froſts come to injure the Shoots, and ſo will be in no Danger of decaying; and by cutting off all the uſeleſs Part of the Branches at this Seaſon, thoſe which are left will be the ſtronger, and the Bloſſom-buds will be better nouriſh'd; for when the Shoots are left to their full Length till Spring, the Buds upon the upper Part of the Branches will be larger than thoſe upon the lower Part, which are thoſe deſigned to be left in Pruning; beſides, by Pruning at this Seaſon, you may dig and clean your Borders before Winter, and ſo will have leſs Buſineſs to do in the Spring, when your Ground is to be cropt.

You may alſo continue to prune Pears, Apples, and Plums, until the Middle or latter End of the next Month, according as the Seaſon proves favourable; but you ſhould never perform this Work in froſty Weather, becauſe then the Shoots would periſh at the Place where they are cut.

If your Soil be dry, this is the beſt Seaſon for tranſplanting all ſorts of Fruit-trees; and if you provide yourſelf from the Nurſeries, you may have much greater Choice at this Seaſon, than in the Spring, when the Nurſeries are generally clear'd of the beſt Trees: But in Planting you ſhould not head down thoſe Trees which are deſigned for Walls or Eſpaliers until the Spring, the Roots only ſhould be pruned; and when the Trees are planted, their Branches ſhould be faſten'd to the Wall, Pale, Eſpalier, or Stakes, to prevent their being looſen'd by the Winds; and ſome Mulch ſhould be laid upon the Surface of the Ground about their Roots, to prevent the Froſt from penetrating to them.

Plant Gooſeberries, Currants, Raſpberries, and Strawberries, that they may take Root before Winter; for thoſe which are planted at this Seaſon will produce Fruit the following Summer, whereas thoſe planted in Spring, have ſeldom Strength enough to produce any (or at leaſt very few) until the ſecond Year.

You may now tranſplant Stocks of all Kinds of Fruits into the Nurſery, to graft or bud the more generous Kinds of Fruits upon; in doing of which, if you obſerve to mulch the Ground about their Roots, to keep the Froſt out, it will be of great Service to them.

Your Beds of Strawberries ſhould now be dreſſed; in doing of which, you muſt clear them from Weeds, and cut off their Strings; then dig up the Alleys, and, after breaking the Earth fine, you ſhould ſpread a little over the Beds, being careful not to bury the Plants. You ſhould alſo clear your Raſpberries of old Wood, and dig up the Ground between the Rows, which will make the Place neat, and greatly encourage the Plants.

Your Currant-buſhes may now be pruned, and then their Branches may be tied up with a Withy, and the Ground between them dug, which may be planted with Coleworts or Cabbage-Plants, to remain till Spring, in which Place they will ſometimes abide the Winter, when they are deſtroy'd in more open Situations; for the Currant-buſhes will prevent the Froſt from penetrating ſo deep into the Ground as it will where the Ground is intirely clear: You may alſo prune Gooſeberry-buſhes, and dig up the Ground between them; and where there is Room, you may plant ſome of the like ſort of Plants, which will be gone in the Spring, before the Buſhes do put out their Leaves.

Preſerve the Stones or Kernels of ſuch ſort of Fruit as you intend to propagate for Stocks, in Sand, until the Seaſon for ſowing of them; but you muſt place them out of the Way of Mice and Rats, which will deſtroy them, if they get to them: and whenever you put any of them into the Ground, the ſame Caution muſt be obſerved; for theſe Vermin will ſoon deſtroy all your Kernels, where they can come to them, if they are not prevented.

Fruits in prime, or yet laſting.

You have yet the Bloody, Malacoton, and ſome Katharine Peaches, Grapes, late Figs, Medlars, Services, Black and White Bullace, with Walnuts, Hazle-nuts, and Almonds.

Pears; The Doyenne or St. Michael, Beurre rouge, Swiſs Bergamot, Verte-longue, Long-ſtalk'd Muſcat, Monſieur Jean, Rouſſeline, Green Sugar, Beſidery, Swan's-egg, with ſome others of leſs Note.

Apples; Golden Rennet, Autumn Pearmain, Red Calville, White Calville, Rennet Griſe, Royal Ruſſet, Embroidered Apple, with ſome others.

Work to be done in the NURSERY.

The Beginning of this Month you ſhould continue to trench the Ground for planting out young Stocks, to graft and bud your ſeveral Sorts of Fruits upon; as alſo to plant out flowering Shrubs, and other Wilderneſs Trees. And about the Middle of the Month you may begin tranſplanting of them into Quarters, placing them in Rows, allowing them a proper Diſtance, according to their ſeveral Sorts.

This Month is the moſt proper Seaſon for tranſplanting all Sorts of hardy Trees, eſpecially in dry Soils; for at this Time they will ſoon puſh out new Roots, which will be eſtabliſhed before the Drought of the ſucceeding Summer, whereby the Trees will be in much leſs Danger of ſuffering than thoſe tranſplanted in the Spring. But you muſt be careful to ſtake all Standard Trees, and thoſe planted againſt Walls, Pales, or Eſpaliers, ſhould be faſten'd thereto, otherwiſe the Wind will turn them aſide, and thereby tear the tender Fibres, to the great Injury of the Trees.

In dry Weather carry Dung into ſuch Parts of the Nurſery where it is wanted, and ſpread it upon the ſurface of the Ground round the Stems of your young Trees; this will keep the Froſt out of the Ground, and the Rains of Winter will waſh in the Salts to the Roots of the Trees; and in the Spring, when the Ground is dug between the Trees, the Dung may be buried.

You may now put into Beds, the Stones of *Muſcle Plums* for Stocks, obſerving to cover them an Inch thick with light Earth, and then lay ſome light Mulch over the Surface of the Bed, to keep out the Froſt, and prevent the Mice from getting to them.

This is the proper Seaſon to ſow Acorns, which will ſprout if they are kept long out of the Ground, and are thereby ſpoiled. You may alſo ſow Beach-maſt ſo ſoon as it is ripe; for this will not keep long out of the Ground. Hawthorns of all ſorts, Yewberries, and Hips of Roſes ſhould now be ſown, obſerving to cover the Beds, as was directed for the Muſcle Plums; theſe Seeds, ſown at this Seaſon, will often come up the ſucceeding Spring, whereas thoſe ſown in the Spring, if they do grow, will not come up until the Spring following.

This is alſo the beſt Seaſon for ſowing Maple-ſeed; for thoſe which are kept out of the Ground till Spring, do rarely grow.

You may now make Layers of Elms, Limes, and all other hardy Trees which ſhed their Leaves; the doing of which at this Seaſon will greatly promote their taking Root; for their Moiſture in Winter will ſettle the Ground about them, and prepare them for puſhing out Roots early in the Spring.

Work to be done in the FLOWER-GARDEN.

The Beginning of this Month you ſhould finiſh planting all the ſorts of Flower-roots which you intend to put into the Ground before *Chriſtmas*; as Tulips, Anemonies, Ranunculus's, Crocus's, Jonquils, Hyacinths, and all ſuch as have been kept above Ground ſince their Leaves decay'd in Summer; for if any of the Roots are ſuffer'd to remain in the Ground a ſhort Time after their Leaves are decay'd, they will puſh out freſh Fibres, when it will be too late to take them up, or, if they are removed, they muſt be immediately planted again; for if they are kept out of the Ground, they will decay in a ſhort Time.

You may now tranſplant moſt ſorts of hardy tuberoſe-rooted or fibroſe-rooted Plants, ſuch as Hollyhocks, Canterbury-bells, French Honeyſuckles, Columbines, Monk's-hoods, Daizies, Buphthalmums, Polyanthus's, Sweet-Williams, London Pride, Campanula's, Aſter's, Golden Rods, Spiderwort, Lychnis Coronaria, Ragged Robin, with many other ſorts, which may be planted in the Borders of the Flower-Garden, obſerving to intermix them in ſuch a manner, that there may be a ſucceſſion of Flowers preſerved throughout the Seaſon.

Cleanſe all the Borders of the Flower-Garden from Weeds, and if you did not dig them the former Month, it muſt now be done, obſerving to renew them with freſh Earth, or ſome very rotten Dung, in the Manner directed in the former Month: You may alſo continue to plant Box-Edgings to Borders, where they are wanted, and repair thoſe which are decay'd.

Thoſe Borders which were dug and planted the Beginning of *September*, ſhould now be raked over again, which will deſtroy all young Weeds, and make the Borders clean and handſome all the Winter-ſeaſon.

Tranſplant Flag-leav'd Iris's, Peonies, and ſuch Geranium as have thick knobby Roots, which ſucceed better when they are planted at this Seaſon, than thoſe which are removed in the Spring.

Your Beds of ſeedling Hyacinths, Tulips, Fritillaria's, and other bulbous-rooted Flowers, which have remained in the Ground all the Year, muſt now be carefully clear'd from Weeds, and ſome freſh rich Earth ſifted over the Beds, about half an Inch thick, which will preſerve the Roots from Froſt, and greatly ſtrengthen them.

The Pots and Boxes of ſeedling Flowers ſhould now be removed out of their ſhady Situation, where they have remained during the Heat of Summer and Autumn, and placed in a warmer Poſition, where they may enjoy as much of the Benefit of the Sun as poſſible, and be ſcreen'd from cold Winds; they ſhould alſo be cleaned from Weeds, and have a little freſh Earth ſifted over them; but this muſt not be laid too thick, leſt the Roots ſhould be buried, and rot in the Ground.

Remove your Pots of choice Carnations under Cover, where they may be defended from violent Rains, Snow, and ſevere Froſt, all which are Enemies to theſe Flowers; therefore if you have planted them in ſmall Half-penny Pots, as was directed in the Month of *Auguſt*, they may be placed very cloſe together in a Garden Frame, or upon a Bed arch'd over with Hoops, that they may be cover'd with Mats in bad Weather; but in mild dry Weather they cannot have too much Air.

Your Pots of choice Auricula's ſhould have their decay'd Leaves taken off, and the Pots muſt be laid on one Side, to prevent their receiving too much Wet, which will be apt to rot them; but they will endure Cold very well.

You may now remove moſt ſorts of flowering Shrubs and Trees, as Roſes, Honeyſuckles, Spaniſh Broom, Cytiſſus's, Laburnums, *&c.* which, if planted at this Seaſon, will take Root before Winter, whereby they will be in leſs Danger of ſuffering from Drought the following Spring, and many of them will flower the next Summer; whereas thoſe which are removed in the Spring will require to be conſtantly water'd in dry Weather, and do rarely flower the ſame Year: But thoſe Shrubs which are planted at this Seaſon muſt have ſome Mulch laid upon the Surface of the Ground about their Stems, to prevent the Froſt from penetrating the Earth to their Roots.

Clean the Walks near your Wilderneſſes of the Leaves which have fallen from the Trees, for if they are ſuffered to rot upon Graſs Walks, they will greatly injure the Graſs; and if they remain upon Gravel Walks to rot, they will diſcolour the Gravel, and render it unſightly: And where you have large

Gravel Walks, which are ſeldom uſed in Winter, you may now break them up, and lay them in Ridges, which will prevent Weeds and Moſs from growing thereon in Winter, and preſerve the Gravel freſh.

Where you have any Ground which is deſign'd to be laid out for Pleaſure, either in a Flower-Garden or Wilderneſs, which you can't get ready for planting before Spring, you ſhould loſe no Time at this Seaſon in preparing of it, that it may be expos'd to the Froſt in Winter, which will mellow it; beſides, if the Froſt ſhould continue long, it may prevent your working till the Seaſon will be too far ſpent for planting, whereby a whole Seaſon will be loſt.

Plants now flowering in the PLEASURE-GARDEN.

Several ſorts of Starworts, Africans, French Marygolds, Marvel of Peru, four or five ſorts of Golden Rod, Autumnal Crocus's, Yellow Autumnal Narciſſus, Cyclamens, Colchicums, China Pinks, Sweet Sultans, Polyanthus's, Auricula's, Three-coloured Violet, or Heart's-eaſe, ſome ſingle Anemonies, Sun-flowers, Indian Scabious, with ſome others.

Hardy Trees and Shrubs now in Flower.

Arbutus, or the Strawberry Tree, late Honeyſuckles, Althæa frutex, Paſſion-flower, Cytiſſus lunatus, Ketmia Syriaca, Lauruſtinus's, Monthly Roſe, Muſk Roſe, Shrub Cinquefoil, with ſome others.

Work to be done in the GREEN-HOUSE *and* STOVE.

The Beginning of this Month you ſhould remove your Orange-trees into the Green-houſe, obſerving, as hath already been directed, to do it in a dry Day, as alſo to clean their Heads and Stems before they are houſed, and ſtir the Earth on the Top of the Tubs, adding a little very rotten Neat's Dung thereto; which will refreſh the Trees, and prevent Moſs from growing in the Tubs or Pots.

You muſt now alſo carry into the Conſervatory your tender Geraniums, Double Indian Naſturtium, Spaniſh Jaſmines, Azorian Jaſmines, Yellow Indian Jaſmines, Ficoides's, Sedums, Cotyledons, Amber Tree, with many other Sorts which are hardy enough to remain abroad until Morning Froſts begin to come on, when they ſhould be removed into Shelter; but theſe muſt have as much free Air as poſſible when they are in the Houſe; for if they are too cloſely ſhut up, their Leaves will decay and fall off; they muſt alſo be frequently refreſh'd with Water, and the decay'd Leaves conſtantly pick'd off.

If you have not already renew'd your Bark-beds in the Stove, it muſt now be no longer deferr'd, for the Cold increaſing will check your tender Exoticks, if they are not placed into new Beds; in doing of which you muſt be very careful not to plunge the Pots into the Bark until it begins to warm, nor ſhould they be put into the Bark if it be too hot, for if the Roots of the Plants are ſcorch'd with the Heat, they rarely recover again. You muſt alſo obſerve to waſh the Leaves and Stems of ſuch Plants as have contracted any Filth, or that are infeſted with Inſects, otherwiſe they will ſpread themſelves over whatever Plants are plac'd near them, and be very injurious to them.

Toward the Latter-end of the Month you ſhould remove your Myrtles, Oleanders, Lentiſcus's, and other hardy Exotick Plants into the Green-houſe, at which Time you ſhould put all the Plants into the Order they are to remain during the Winter, obſerving (if you have Room in the Green-houſe) to place them in ſuch a Manner that the Branches of the Plants may not interfere with each other, but that their Heads may ſtand ſingle, that the Air may freely paſs between them.

Your Anana's, or Pine Apples, muſt now be removed out of the Bark-bed, where they have remain'd the laſt Summer, and plac'd in the Stove near the Fire, that they may enjoy the Heat; but you muſt obſerve to refreſh them frequently with Water, which ſhould be plac'd in the Stove twenty-four Hours before it be uſed, that it may acquire a proportionable Warmth with the Air of the Houſe; for if you permit the Fibres of the Plants to grow dry, it will weaken the Plants, and cauſe many of your laſt Year's Crowns and Off-ſets to fruit, which were not deſigned for fruiting the following Year, and ſo conſequently their Fruit will be very ſmall, and of little Value.

Toward the End of the Month, as you find the Nights to grow cold, you muſt begin to make Fires in the Stoves; but this muſt be done with Caution, for if you make the Heat too great, it will cauſe the Plants to ſhoot, whereby they will be weaken'd, and the Seaſon being too far advanc'd to permit their Shoots to grow ſtrong, their Leaves will often decay and fall off. You muſt alſo obſerve to refreſh your Plants with Water pretty often, for when you begin to make Fires, it will dry the Air of the Houſe, and occaſion the Plants to perſpire more freely than before, whereby they will require more Water; but you muſt not give it to them in large Quantities, but rather frequently, and a little at each Time. When you obſerve the Leaves of any Plants decay, you ſhould pick them off, and keep the Stove conſtantly clear from any fallen Leaves, Cobwebs, or other Filth; which not only renders the Houſe neat, but is very neceſſary to preſerve your Plants in Health.

Plants now in Flower in the GREEN-HOUSE *and* STOVE.

The ſcarlet-flowering Geranium, Geranium with an Aſarabacca Leaf, Ficoides's of ſeveral ſorts, Cotyledons, Chryſanthemums, Spaniſh Jaſmine, Arabian Jaſmine, Ilex-leav'd Jaſmine, Indian yellow Jaſmine, Anemonoſpermos's, Perſian Cyclamens, Aloes of many Kinds, Canary Campanula, Caſſia Bahamenſis, Senſitive and Humble Plants, Guernſey Lily, Belladona Lily, Three-leav'd Paſſion-flower, Alaternoides ericæ folio, Leonurus, Euphorbium nerii folio, Alcea groſſulariæ folio, Double-flowering Myrtle, Yucca Indica, Polygala arboreſcens, Myrto-Ciſtus, Papaya, Ketmia ſemine moſchato, Senecio folio retuſo, Opuntia's, with ſome others.

OCULUS CHRISTI. *Vide* Horminum Sylveſtre.

OCYMUM, Baſil.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Creſt (or upper Lip) is upright, roundiſh, notched, and larger than the Beard, or lower Lip) which is generally curled, or gently cut. Out of the Flower-cup ariſes the Pointal, attended by four Embryo's, which afterwards become ſo many Seeds incloſed in a Huſk, which was before the Flower-cup; this Huſk is divided into two Lips, the upper one growing upright, and is ſplit into two; but the under one is cut into ſeveral Parts.

The *Species* are;

1. Ocymum *vulgatius. C. B. P.* Common Baſil.
2. Ocymum *vulgatius, foliis ex nigro-vireſcentibus, flore albo. H. R. P.* Common Baſil, with dark-green Leaves, and white Flowers.
3. Ocymum *minus anguſtifolium, foliis ſerratis. C. B. P.* Leſſer Baſil, with narrow ſerrated Leaves.
4. Ocymum *minus anguſtifolium, foliis bullatis. H. R. P.* Leſſer narrow-leaved Baſil, with warted Leaves.
5. Ocymum *minimum. C. B. P.* The leaſt Baſil, commonly called *Buſh-Baſil.*
6. Ocymum *minimum, foliis ex purpurâ nigricantibus. H. R. P.* The leaſt Baſil, with dark-purple Leaves.
7. Ocymum *citri odore. C. B. P.* Baſil with a citron Scent.
8. Ocymum *latifolium maculatum vel criſpum. C. B. P.* Broad-leav'd Baſil, with curled ſpotted Leaves.
9. Ocymum *folibrum fimbriis ad endiviam accedentibus, maximum. H. L.* The greateſt Baſil, with Leaves fringed like Endive.
10. Ocymum *foliis fimbriatis viridibus. C. B. P.* Baſil with fringed green Leaves.
11. Ocymum *caryophyllatum maximum. C. B. P.* The greateſt Baſil, ſmelling like Cloves.
12. Ocymum *aniſi odore. C. B. P.* Baſil ſmelling like Aniſe.
13. Ocymum *minus anguſtifolium, foliis ſerratis. C. B. P.* The ſmaller narrow-leaved Baſil, with ſawed Leaves.
14. Ocymum *tricolor. H. R. Par.* Three-coloured Baſil.
15. Ocymum *nigrum majus, acuto rutæ odore. H. L.* Greater black Baſil, with the quick Smell of Rue.
16. Ocymum *Campechianum odoratiſſimum. Houſt.* The moſt ſweet-ſmelling Baſil of *Campechy.*

Theſe Plants being annual, are propagated from Seeds, which ſhould be ſown in *March*, upon a moderate Hot-bed; and when the Plants are come up, they ſhould be tranſplanted into another moderate Hot-bed, obſerving to water and ſhade them until they have taken Root; after which they ſhould have Plenty of Air in mild Weather, otherwiſe they will draw up very weak; you muſt alſo water them frequently, for they love Moiſture. In *May* they ſhould be taken up with a Ball of Earth to their Roots, and tranſplanted either into Pots or Borders, obſerving to ſhade them until they have taken Root; after which they will require no farther Care, but to clear them from Weeds, and refreſh them with Water in dry Weather. Tho' theſe Plants are only propagated from Seeds, yet if you have any particular Sort which may ariſe from Seeds, which you are deſirous to increaſe, you may take off Cuttings any Time in *May*, and plant them on a moderate Hot-bed, obſerving to water and ſhade them for about ten Days; in which Time they will take Root, and in three Weeks Time will be fit to remove either into Pots or Borders, with the ſeedling Plants. In *Auguſt* theſe Plants will perfect their Seeds, when thoſe Sorts which appear the moſt diſtinct, ſhould have their Seeds preſerved ſeparate, for ſaving the following Spring.

The firſt Sort is what the College of Phyſicians have preſcribed for medicinal Uſe; but the fifth Sort is moſt eſteemed for its Beauty and Scent, by thoſe who cultivate them to adorn their Gardens.

The Seeds of theſe Plants are uſually brought from the South of *France*, or *Italy*, every Spring, becauſe they ſeldom ripen their Seeds in this Country, in the open Air. But whoever is curious to preſerve the Seeds of any of the Varieties, ſhould place them into an airy Glaſs-caſe or Stove, in the Autumn when the Weather begins to be cold or wet; and by ſupplying them with Water, and letting them have free Air every Day in mild Weather, they will perfect their Seeds very well in this Country.

The ſixteenth Sort is more tender than any of the other. This was diſcovered growing wild at *Campechy*, by the late Dr. *William Houſtoun*, who ſent the Seeds to *England*. This ſhould be ſown on a Hot-bed early in the Spring, and when the Plants are come up, they ſhould be tranſplanted on another very temperate Hot-bed, to bring them forward; and when they have obtained Strength, they ſhould be each tranſplanted into a ſeparate Pot, and placed either in the Stove, or on a moderate Hot-bed, where they may have a large Share of Air in warm Weather; but by being ſheltered from the Cold and Wet, the Plants will perfect their Seeds very well in *England*.

ŒNANTHE, [Οἰνάνθη, of οἴνη a *Vine*, and ἄνθος a *Flower*. The Ancients call'd any Plant *OEnanthe* that flower'd at the ſame Time with the Vine, or whoſe Flowers had the ſame Odour.] Water Dropwort.

The *Characters* are;

It is an umbelliferous Plant, whoſe Flower conſiſts of many Heart-ſhap'd Leaves, which expand in Form of a Roſe: The Ovary is fix'd to the Top of the Empalement, which turns to a Fruit compoſ'd of two oblong Seeds, that are gibbous and ſtreak'd on one Side, and plain on the other, ending, as it were, in ſome Prickles, the middlemoſt of which is ſtronger than the reſt.

The *Species* are;

1. Œnanthe *cicutæ facie Lobelli. Park. Theat.* Hemlock Dropwort.
2. Œnanthe *aquatica. C. B. P.* Water Dropwort.

There are ſeveral other Species of this Plant, ſome of which are Natives of *England*; but as they are not at preſent uſeful, nor of any Beauty, I ſhall omit enumerating them in this Place.

The firſt of thoſe here mention'd is very common by the Side of the *Thames* on each Side *London*, as alſo by the Sides of large Ditches and Rivers in divers Parts of *England*: This Plant commonly grows four or five Feet high with ſtrong-jointed Stalks, which being broke, do emit a yellowiſh fœtid Juice: The Leaves are ſomewhat like thoſe of the common *Hemlock*, but are of a lighter-green Colour: The Roots divide into four or five large taper ones, which, when ſeparated, have ſome Reſemblance to *Parſnips*; for which ſome ignorant Perſons have taken and boil'd them, whereby Themſelves and Family have been poiſon'd.

The poiſonous Quality of this Plant hath led ſome Perſons to believe it is the *Cicuta* of the Ancients: But, according to *Wepfer*, the *Sium alterum Oluſatri facie* of *Lobel* is what the Ancients call'd *Cicuta*, as may be ſeen at large in *Wepfer's* Book *de Cicuta*.

The ſecond Sort is very common in moiſt Soils, and by the Sides of Rivers in divers Parts of *England*: This is not ſuppos'd to be near ſo ſtrong as the firſt, but is of a poiſonous Quality.

All the Sorts of theſe Plants do naturally grow in moiſt Places; ſo that whoever hath a mind to cultivate them ſhould ſow their Seeds ſoon after they are ripe in Autumn, upon a moiſt Soil, where they will come up, and thrive exceedingly the following Summer, and require no farther Care but to clear them from Weeds.

OLDENLANDIA.

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of one Leaf, which is divided into four Parts almoſt to the Bottom, and reſts on the Empalement; which Empalement afterward becomes an almoſt globular Fruit, having two Cells, which contain many ſmall Seeds.

We have but one *Species* of this Plant, which is,

Oldenlandia *humilis hyſſopi folio. Plum. Nov. Gen.* Dwarf Oldenlandia, with a hyſſop Leaf.

This Plant was diſcovered in *America* by Father *Plumier*, who gave this Name to it in Honour to *Henry Bernard Oldenland* a *German*, who was a Diſciple of Dr. *Herman* at *Leyden*, and was a very curious Botaniſt.

The Seeds of this Plant were ſent into *England* by Mr. *Robert Millar*, who gathered them in *Jamaica*. It is a low annual Plant, which ſeldom riſes above three or four Inches high, and divides into many Branches, which ſpread near the Ground. Theſe Branches are furniſhed with long narrow Leaves, which are placed by Pairs oppoſite to each other. From the Wings of the Leaves ariſes the Flower-ſtalk, which grow about an Inch or a little more in Length, and divides into three or four ſmaller Foot-ſtalks: On the Top of each of theſe, ſtands one ſmall white Flower.

The Seeds of this Plant ſhould be ſown early in the Spring, on a Hot-bed; and when the Plants are come up, they ſhould be tranſplanted on another Hot-bed, or into ſmall Pots, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which Time, they muſt have a large Share of free Air in warm Weather, and muſt be frequently refreſhed with Water. With this Management the Plants will flower in *June*, and their Seeds will ripen ſoon after; ſo that the Seeds muſt be gathered from time to time as they ripen; for as the Branches grow larger, ſo there will be freſh Flowers produced until Autumn, when the Plants will periſh: But if the Seeds are permitted to ſcatter in the Pots, the Plants will ſoon after appear, which will live thro' the Winter, provided they are placed in the Stove; ſo will flower early the following Spring.

OLEA, [of 'Ελαία.] The *Olive*.

The *Characters* are;

The Leaves are, for the moſt part, oblong and ever-green; the Flower conſiſts of one Leaf; the lower part of which is hollow'd, but the upper part is divided into four Parts; the Ovary, which is fix'd in the Center of the Flower-cup, becomes an oval, ſoft, pulpy Fruit, abounding with a fat Liquor, incloſing a hard rough Stone.

The *Species* are;

1. Olea *ſativa. C. B. P.* The manur'd *Olive*.
2. Olea *Africana, folio longo lato ſupra atroviridi ſplendente, infra pallidè viridi. Boerh. Ind.* African Olive, with a broad long Leaf, of a ſhining dark-green Colour on the upper-ſide, but of a paler-green underneath.
3. Olea *Africana, folio buxi craſſo atroviridi lucido, cortice albo ſcabro. Boerh. Ind.* The African Box-leaved Olive.
4. Olea *minor Lucenſis, fructu odorato. Tourn.* The Luca Olive.
5. Olea *fructu majori, carne craſſa. Tourn.* Olive, with a larger Fruit, having a thicker Pulp.
6. Olea *ſylveſtris, folio molli incano. C. B. P.* The Oleaſter or Wild *Olive*, with ſoft hoary Leaves.

Theſe five firſt Sorts are preſerv'd in the Gardens of the Curious, where they are planted either in Pots or Caſes, and remov'd into the Green-houſe in the Winter, with *Oranges*, *Myrtles*, &c. but they are moſt of them hardy enough to endure the Cold of our ordinary Winters in the open Air, provided they are planted upon a dry Soil, and in a warm Situation; tho' in ſevere Winters they are often demoliſh'd, or at leaſt loſe their Heads, or are kill'd to the Surface; but this is what they are liable to in the South Parts of *France*, in which Country theſe Trees abound; and yet in very ſharp Winters are moſt of them deſtroy'd. There was a Parcel of theſe Trees growing in the Gardens of *Cambden-houſe* near *Kenſington* a few Years ſince, which were ſeven or eight Feet high, and in ſome good Seaſons did produce very good Fruit: Theſe were planted againſt a South-Wall, but were permitted to grow up rude without pruning, or faſtening to the Wall, (which they do by no means care for); and during the Time they were below the Top of the Wall, they throve very well; but after their Heads were gotten above the Wall, the North-Winds did uſually every Winter greatly prejudice them, and I believe the hard Winter [1709.] did intirely demoliſh them.

Theſe Plants may be propagated by laying down of their tender Branches, (in the manner practis'd for other Trees) which ſhould remain undiſturb'd two Years; in which Time they will have taken Root, and may then be taken off from the old Plants, and tranſplanted either into Pots fill'd with freſh light Earth, or into the open Ground in a warm Situation. The beſt Seaſon for tranſplanting them is the Beginning of *April*; when you ſhould, if poſſible, take the Opportunity of a moiſt Seaſon, and thoſe which are planted in Pots, ſhould be plac'd in a ſhady Part of the Green-houſe until they have taken Root; but thoſe planted in the Ground ſhould have Mulch laid about their Roots, to prevent the Earth from drying too faſt, and now and then refreſh'd with Water, but you muſt by no means let them have too much Moiſture, which will rot the tender Fibres of their Roots, and deſtroy the Trees. When the Plants have taken freſh Root, thoſe in the Pots may be expoſ'd to the open Air, with other hardy Exoticks, with which they ſhould be hous'd in Winter, and treated as *Myrtles* and other leſs tender Trees and Shrubs; but thoſe in the open Air will require no farther Care until the Winter following, when you ſhould mulch the Ground about their Roots, to prevent the Froſt from penetrating deep into it: And if the Froſt ſhould prove very ſevere, you ſhould cover them with Mats, which will defend them from being injur'd thereby; but you muſt be cautious not to let the Mats continue over them after the Froſt is paſt, leſt by keeping them too cloſe, their Leaves and tender Branches ſhould prove mouldy for want of free Air, which will be of as bad Conſequence to the Trees as if they had been expoſ'd to the Froſt, and many Times worſe; for it ſeldom happens, if they have taken much of this Mould, or have been long cover'd, ſo that it has enter'd the Bark, that they are ever recoverable again; whereas it often happens, that the Froſt only deſtroys the tender Shoots, but the Body and larger Branches remaining unhurt, do put out again the ſucceeding Spring.

Theſe Trees are generally brought over from *Italy* every Spring, by the Perſons who bring over the *Oranges*, *Jaſmines*, &c. from whom they may be procur'd pretty reaſonable, which is a better Method than to raiſe them from Layers in this Country, that being too tedious; and thoſe which are thus brought over, have many times very large Stems, to which Size young Plants in this Country would not arrive in ten or twelve Years Growth. When you firſt procure theſe Stems, you ſhould (after having ſoak'd their Roots twenty-four Hours in Water, and clean'd them from the Filth they have contracted in their Paſſage) plant them in Pots fill'd with freſh, light, ſandy Earth, and plung'd into a moderate Hot-bed, obſerving to ſcreen them from the Violence of the Sun in the Heat of the Day, and alſo to refreſh them with Water, as you ſhall find the Earth in the Pots dry. In this Situation they will begin to ſhoot in a Month or ſix Weeks after; when you ſhould let them have Air in Proportion to the Warmth of the Seaſon: And after they have made pretty good Shoots, you ſhould inure them to the open Air by degrees; into which they ſhould be remov'd, placing them in a Situation where they may be defended from ſtrong Winds: In this Place they ſhould remain till *October* following; when they muſt be remov'd into the Green-houſe, as was before directed. Having thus manag'd theſe Plants until they have acquir'd ſtrong Roots, and made tolerable good Heads, you may draw them out of the Pots, preſerving the Earth to their Roots, and plant them in the open Air in a warm Situation, where you muſt manage them as was before directed for the young ones, and theſe will in two or three Years produce Fruit, provided they do well. The *Luca* and *Box-leav'd Olives* are the hardieſt, for which Reaſon they ſhould be preferr'd to plant in the open Air, but the firſt Sort will grow to be the largeſt Trees.

The *Oleaſter* is very hardy, and will endure the ſevereſt Cold of our Climate, provided it have a dry Soil, and is not too much expoſ'd to the cold Winds. This will grow to the Height of ſixteen or eighteen Feet, and make a large Head; and if planted among other Exotick Trees in Wilderneſs-Quarters, will greatly add to their Variety by its Silver-colour'd Leaves; and during the Seaſon of its Flowering, (which is in *June*) it perfumes the circumambient Air to a great Diſtance, tho' the Flowers are very ſmall, and of little Beauty. This ſometimes produces Fruit in *England*, when the Trees are pretty old, but it often happens, that if they bear any Quantity of Fruit, they die ſoon after.

This Tree may be propagated by laying down the tender Branches, which will take Root in one Year's time; at which time they may be taken off from the old Plants, and plac'd where they are to remain, for they do not care to be often tranſplanted. The beſt Seaſon for removing them is the Latter-end of *March*, or the Beginning of *April*, juſt before the Leaves come out; when you ſhould alſo obſerve to mulch the Ground about their Roots, and refreſh them with Water, as they may require it; and after they have taken good Root in the Ground, they will grow very quick, and in two or three Years will produce Flowers.

OMPHALODES, [of ὀμφαλὸς, a *Navel*, and εἶδος *Shape*, becauſe the *Calyx* is hollow'd like the human Navel] Venus Navel-wort.

The *Characters* are;

The Flower conſiſts of one Leaf, which expands in a circular Order, and is cut into ſeveral Segments; the Pointal, which riſes in the Middle of the Flower, becomes a Fruit, compoſ'd of four hollow, umbilicated Capſules, ſomewhat reſembling a Baſket; in each of which is contain'd one almoſt flat Seed adhering to the Placenta, *which is pyramidal and four-corner'd.*

The *Species* are;

1. OMPHALODES *Luſitanica, lini folio. Tourn.* Venus Navel-wort, *vulgo*.
2. OMPHALODES *Luſitanica elatior, cynogloſſi folio. Tourn.* Taller Portugal Navel-wort, with a Hound's-tongue Leaf.
3. OMPHALODES *pumila verna, ſymphyti folio. Tourn.* Low Vernal Venus Navel-wort, with a Comfry-leaf, *or* Leſſer Borage.

The firſt of theſe Plants hath been a long Time in the *Engliſh* Gardens. The Seeds of this Kind are ſold in the *London* Shops, as a Dwarf annual Flower, to be uſ'd for Edgings; for which Purpoſe it is by no means proper, for it often happens, that not a tenth Part of the Seeds do grow, tho' they were ſav'd with all poſſible Care, ſo that the Plants will be very thin, and in Patches; but however, it is a pretty Ornament to the Borders of the Pleaſure-Garden, if ſown in Patches, as hath been directed for the *Dwarf Lychnis*, and other annual Plants of the ſame Growth; amongſt which this Plant makes a pretty Variety. The Seeds of it ſhould be ſown in Autumn, ſoon after they are ripe; at which Seaſon they will come up very well, (whereas thoſe ſown in the Spring do ſeldom ſucceed) and the Plants will abide the Cold of our ordinary Winters, and will flower early the ſucceeding Spring, from which Plants you will have good Seeds in *July*; but thoſe ſown in the Spring do very often fail of ripening Seeds.

The ſecond Sort is only in ſome curious Botanick Gardens at preſent, though it is equally as hardy as the firſt, and muſt be treated in the ſame Manner. This grows taller, and hath broader Leaves than the firſt, in which reſpects the only Difference between them conſiſts.

The third Sort is an abiding Plant, and multiplies very faſt by its trailing Branches, which take Root at their Joints as they lie upon the Ground, and may be taken off, and tranſplanted to make new Plants. Theſe require a moiſt Soil, and a ſhady Situation, where they will thrive exceedingly, and produce great Quantities of pretty blue Flowers early in the Spring, for which it is chiefly valued.

ONAGRA; Tree Primroſe, *vulgo*.

The *Characters* are;

It hath a Roſe-flower, conſiſting generally of four Leaves, placed orbicularly, and reſting on the Empalement; out of whoſe upper Part (which is fiſtulous) riſes the Pointal, the under Part turning to a Fruit which is cylindrical, gaping in four Parts, and divided into four Cells filled with Seeds, which are generally cornered, and adhere to the Placenta.

The *Species* are;

1. ONAGRA *latifolia. Inſt. R. H.* Broad-leaved Tree-Primroſe.
2. ONAGRA *latifolia, flore dilutiore. Inſt. R. H.* Broad-leaved Tree-Primroſe, with paler yellow Flowers.
3. ONAGRA *latifolia, floribus amplis. Inſt. R. H.* Broad-leaved Tree-Primroſe, with ample Flowers.
4. ONAGRA *anguſtifolia. Inſt. R. H.* Narrow-leaved Tree-Primroſe.
5. ONAGRA *anguſtifolia, caule rubro, flore minori. Inſt. R. H.* Narrow-leaved Tree-Primroſe, with red Stalks, and a ſmaller Flower.
6. ONAGRA *Americana, foliis perſicariæ amplioribus, parvo flore luteo. Plum.* American Tree-Primroſe, with ample arſmart Leaves, and a ſmall yellow Flower.
7. ONAGRA *Americana, foliis perſicariæ anguſtioribus, magno flore luteo. Plum. Cat.* American Tree-Primroſe, with narrower arſmart Leaves, and a large yellow Flower.
8. ONAGRA *Americana fruteſcens, nerii folio, magno flore luteo. Plum. Cat.* American Tree-Primroſe, with an Oleander Leaf, and a large yellow Flower.
9. ONAGRA *Americana, folio betonicæ, fructu hiſpido. Plum. Cat.* American Tree-Primroſe, with a betony Leaf, and a prickly Fruit.

10. **Onagra** *laurifolia, flore amplo pentapetalo. Feuillée.* Bay-leaved Tree-Primroſe, with a large five-leaved Flower.

11. **Onagra** *hyſſopifolia, flore amplo violaceo. Feuillée.* Hyſſop-leaved Tree-Primroſe, with a large violet-coloured Flower.

12. **Onagra** *linariæ folio, magno flore purpureo. Feuillée.* Tree-Primroſe, with a Toad-flax Leaf, and a large purple Flower.

13. **Onagra** *ſalicis anguſto dentatoque folio, vulgo Mithon. Feuillée.* Tree-Primroſe with narrow indented Willow Leaves, commonly called Mithon.

14. **Onagra** *ſalicis anguſto dentatoque folio, flore luteo, calyce prælongo. Feuillée.* Tree-Primroſe with narrow indented Willow Leaves, a yellow Flower, and a longer Cup.

The firſt Sort is very common in moſt *Engliſh* Gardens, where, when it has been ſuffered to ſcatter its Seeds, it will come up and flouriſh without any Care, and many Times becomes a troubleſome Weed: This will thrive in the Smoak of *London*, ſo that it is a very proper Plant to adorn the City Gardens; for it continues in Flower from the Beginning of *June* until *Auguſt*, and ſometimes in cold Seaſons until near *Michaelmas*. The Flowers of this Plant do not open in the Middle of the Day, when the Weather is warm; but in the Evening, after the Sun is gone off, they open, and continue ſo, until the Sun comes on them the next Day; in cloudy Weather the Flowers will continue open all Day, or when the Plants grow in the Shade. This Manner of the Flower opening in the Evening, has occaſioned the Name of *Night Primroſe*, by which ſome People call it. The four next mentioned are equally hardy, and will grow in almoſt any Soil or Situation. The Seeds of theſe Plants may be ſown in *March*, in an open Situation; and when the Plants come up, they ſhould be kept clean from Weeds; and where they come up too cloſe, ſome of them ſhould be pulled up, to allow Room for the others to grow. In this Place the Plants may remain till *Michaelmas*, when they ſhould be tranſplanted where they are to remain for flowering. Theſe Plants produce a great Quantity of Seed, which, if permitted to ſcatter, will ſufficiently ſtock the Garden with Plants; but the old Plants rarely continue after they have ſeeded.

Tho' theſe Plants will bear tranſplanting pretty well, if it be done at *Michaelmas*, yet it is the better Way to ſow the Seeds, where the Plants are deſigned to remain for flowering, becauſe they generally have a downright Root, which is often cut or broken by tranſplanting; and then the Plants never thrive ſo well, nor continue ſo long in Flower, as thoſe which remain undiſturbed.

The ſixth and ſeventh Sorts are much tenderer than the former, and require to be raiſed in a Hot-bed, where they muſt be treated as hath been directed for the *Balſamina* and *Amaranthus's*; to which I refer the Reader, to avoid Repetition. Theſe Plants ſhould be kept in a Stove or Glaſs-caſe, where they ſhould have a large Share of Air in warm Weather; but if they are expoſed in the open Air, they ſeldom continue long in Beauty, and rarely perfect their Seeds in *England*.

The eighth Sort is hardy, and will do very well in the open Air, provided it is ſown on a warm Soil, and in a ſheltered Situation. The Seeds of this Kind, if permitted to ſcatter, will come up the following Spring, and require no farther Care, but to keep them clear from Weeds. If ſome of theſe Plants are planted in Pots, and ſheltered in the Green-houſe in Winter, they will grow woody, and may be continued two Years or more. But as it is ſo hardy as to come up from the ſcattered Seeds, ſo few People care to have the Trouble of keeping the Plants over the Winter.

The ninth, tenth, eleventh, twelfth, thirteenth, and fourteenth Sorts, are more tender: Theſe ſhould be raiſed on a Hot-bed, and managed as the ſixth and ſeventh Sorts; by which Method good Seeds may be obtained, and the Kinds preſerved.

The tenth Sort was found in the Plains of *Lima*, by Father *Feuillée*: This Sort was alſo found near *Panama* by Mr. *Robert Millar*, Surgeon, who ſent the Seeds to *England*. The eleventh Sort was alſo found by Father *Feuillée* in *Chily*, as were the thirteenth and fourteenth by the ſame Perſon. But the twelfth Sort he found by the River of *Plate*. This grows about a Foot high, and produces large purple Flowers. The eleventh Sort grows fuller, and produces large violet-colour'd Flowers, which renders them more valuable than the other Sorts.

ONIONS. *Vide* Cepa.

ONOBRYCHIS; [of ὄνος an *Aſs*, and βρύχω to *make a Noiſe* or *Bray*, becauſe the Scent of this Plant makes *Aſſes bray*; or becauſe when *Aſſes* eat theſe Husks, they are ſaid always to *bray*] **Cock's Head, *or* Saint-Foin.**

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a creſted Pod, which is ſometimes rough and full of Seeds, ſhap'd like a Kidney; to which may be added, the Flowers grow in a thick Spike.

The *Species* are;

1. **Onobrychis** *foliis viciæ, fructu echinato, major, floribus dilute rubentibus. C. B. P.* Greater Cock's-head, with Vetch Leaves, rough Fruit, and pale-red Flowers.

2. **Onobrychis** *foliis viciæ, fructu echinato, major, floribus eleganter rubentibus. C. B. P.* Greater Cock's head, with Vetch Leaves, rough Fruit, and beautiful red Flowers.

3. **Onobrychis** *fructu echinato, minor. C. B. P.* Smaller Cock's-head, with rough Fruit, *or* Medick Vetchling.

The two firſt are Varieties which only differ in the Colour of their Flowers, the ſame Seeds often producing both Sorts, tho' ſav'd from one Plant: as there is alſo another Variety with a white Flower, which doth come from the ſame Seed, ſo that they may paſs for one Plant.

This is an abiding Plant, which if ſown upon a dry, gravelly, or chalky Soil, will continue eighteen or twenty Years; but if it be ſown upon a deep, light, moiſt Soil, the Roots will run down into the Ground, and in the Winter Seaſon the Moiſture will rot the Roots, ſo that it ſeldom laſts above two Years in ſuch Places.

This is eſteem'd one of the beſt Sorts of Fodder for moſt Cattle, and is a great Improvement to ſhallow, chalky Hills, upon which it ſucceeds better than in any other Soil, and will continue many Years; and the Roots of this Plant, when plough'd in, do greatly inrich the Ground.

The beſt Seaſon for ſowing of this Seed is in the Beginning or Middle of *March*, (according as the Seaſon is early or late) obſerving always to do it in dry Weather, otherwiſe the Seed will be apt to burſt with Moiſture, and ſo never come up. Theſe Seeds being large, there will require a greater Quantity to ſow an Acre: The common Allowance is four Buſhels to an Acre, but I would not adviſe above three at moſt: And if this Seed were ſown in Rows, (in the manner directed for the *Medica*) it would be a great Improvement to the Plants; for when they have Room enough, they are very ſubject to branch out on every Side, and become very ſtrong; ſo that when they are in Rows, that the Ground between them can be ſtirr'd with a Hand-Plough, it will cauſe them to ſhoot much ſtronger than when they grow ſo cloſe that there can be no Culture beſtow'd on them.

I have taken up Roots of this kind, where they have grown ſingly, and kept clear from Weeds, whoſe Shoots have ſpread near two Feet wide, and were much ſtronger than thoſe which grew nearer together upon the ſame Soil.

There are ſome Perſons who recommend the ſowing *Oats* or *Barley* with this Seed, but that is a very bad Method, for what is gain'd from the Crop of *Corn* will be doubly loſt in the *Saint Foin*; and this generally holds true in moſt Sorts of Graſs-Seeds, for the Corn growing over it, doth ſo weaken the Crop beneath, that it ſcarcely recovers its Strength in a Year's Time after.

The Ground in which this Seed is ſown, ſhould be well ploughed and made very fine; and if you ſow it in Rows, the Drills ſhould be made eighteen Inches aſunder, and about an Inch deep, in which the Seed ſhould be ſown indifferently thick; for if the Plants come up too cloſe, it will be very eaſy to hough them out, ſo as to leave the remaining ones ſix or eight Inches aſunder; for the Ground ſhould be houghed, after the Plants are come up, to deſtroy the Weeds, which if ſuffer'd to grow, would ſoon over-bear the young ones, and deſtroy them; but when the Plants have obtain'd Strength, they will prevent the Weeds from growing up amongſt them.

The firſt Year after ſowing, you ſhould by no Means feed it down, for the Crown of the Roots being then young and tender, the Cattle would eat it ſo low as to intirely deſtroy the Roots; and if large Cattle were let in upon it, they would trample it down ſo much as to prevent its ſhooting again: Therefore the firſt Year it ſhould be mowed, which ſhould b done when it is in Flower, being careful to turn it often, th it may the ſooner dry and be remov'd; for while it continue upon the Ground, it greatly retards the Roots from ſhooting again.

The Time when this Crop will be fit to cut the firſt Year, i toward the Latter-end of *July* or the Beginning of *Auguſt* After this is clear'd off, the Roots will ſoon ſhoot again, an by the End of *September* (provided the Seaſon be favourable there will be a fine Crop fit for feeding: At which Time, o ſoon after, you may turn in Sheep, which will, in eatin

dow

down the Graſs, inrich the Ground with their Dung, whereby the Roots will be greatly ſtrengthened; but you ſhould not ſuffer them to remain too long upon it, leſt, as I before obſerv'd, they ſhould eat it down too low, which would deſtroy the Roots; nor ſhould they ever be ſuffer'd to remain upon it longer than the Middle of *March*; after which Time it ſhould be let grow for a Crop, which will be fit to cut the Latter-end of *May*; and if you do not feed it, there will be a ſecond Crop by the End of *July* following, ſo that you may have two Crops every Year, beſides the Advantage of feeding it down in Winter and Spring; and if you obſerve to ſtir the Ground betwixt the Rows, after every Cutting, (as was directed for the *Medica*) it will be of great Service to the Roots, and occaſion the Shoots to be much ſtronger than if wholly neglected, as is the common Practice.

This Sort of Hay is excellently good for Horſes, and is eſteem'd one of the beſt Sorts of Food for moſt Cattle, eſpecially in the Spring, there being no Danger attending it, as there is in *Clover*, and ſome other Sorts of Fodder; it breeds abundance of Milk; and the Butter that is made of it is very good.

And altho' it is ſo common in many Parts of *England*, yet a few Plants of the deep-red flower'd Sort, when diſpos'd in large Borders of the *Pleaſure-Garden*, do afford an agreeable Variety: The Flowers, which are of a beautiful red Colour, being collected into a long Spike, and continuing a long time in Beauty, do make a very pretty Mixture amongſt other Flowers in the Borders of large Gardens, where there is Room; and the Roots will abide ſeveral Years without renewing, requiring very little Culture, being extremely hardy, in reſpect to Heat or Cold, provided they are planted upon a dry Soil.

The third Sort is Annual; nor are the Flowers ſo beautiful as thoſe of the former Sort, for which Reaſon it is ſeldom cultivated, except in Botanick Gardens, for Variety: This may be ſown in the Beginning of *March* upon a light freſh Soil, where the Plants will come up in *April*, and will require no farther Care but to clear 'em from Weeds: The Seeds will ripen in *Auguſt*, when they ſhould be gather'd, and preſerv'd for ſowing the ſucceeding Spring.

OPHIOGLOSSUM, Adders-Tongue.

The *Characters* are;

It hath no viſible Flower, but the Seeds are produced on a Spike which reſemble a Serpent's Tongue; which Seed is contain'd in many longitudinal Cells, which open, and caſt forth the Seeds when ripe.

The *Species* are;

1. OPHIOGLOSSUM *vulgatum. C. B. P.* The common Adders-Tongue.
2. OPHIOGLOSSUM *anguloſo folio. C. B. P.* Adders-Tongue, with an angular Leaf.
3. OPHIOGLOSSUM *minus, ſubrotundo folio. C.B.P.* Leſſer Adders-Tongue, with a roundiſh Leaf.
4. OPHIOGLOSSUM *bilingue majus, folio acuto. Mentz. Pug.* Greater Adders-Tongue, with a pointed Leaf, and a double Tongue.
5. OPHIOGLOSSUM *bilingue medium, folio obtuſo. Mentz. Pug.* Middle Adders-Tongue, with a blunt Leaf, and a double Tongue.
6. OPHIOGLOSSUM *bilingue minimum. Mentz. Pug.* The leaſt Adders-Tongue, with a double Spike or Tongue.
7. OPHIOGLOSSUM *palmatum. Plum.* Handed Adders-Tongue.
8. OPHIOGLOSSUM *cordiforme & reticulatum. Plum.* Heart-ſhaped and netted Adders-Tongue.

The firſt Sort grows wild in moiſt Meadows in ſeveral Parts of *England*. This is directed to be uſed in Medicine by the College of Phyſicians, in their Diſpenſatory; but is ſeldom to be found in Gardens, being very difficult to tranſplant, and will not live long, where the Graſs doth not grow about it. The beſt Method to have it ſucceed, is, to dig up the Plants about the Beginning of *April*, with large Balls of Earth to them, being careful to dig ſo deep, as to get below their Roots; then plant theſe with the Turf about them, in a moiſt ſhady Place, where they will grow pretty well, and may continue for ſome Years.

The ſecond and third Sorts grow wild in *Germany*, and on the *Alpes*, but are not to be found in *England*.

The fourth, fifth, and ſixth Sorts, are alſo Varieties which have been found in ſome Parts of *Europe*; but it is not certain whether they are diſtinct Species, or only Variations from the common Sort.

Theſe are all as hardy as the common Sort; ſo, whenever they are found, may be tranſplanted and treated in the ſame Manner.

The ſeventh and eighth Sorts were diſcovered by Father *Plumier* in *America*. Theſe grow in moiſt ſwampy Places in *Jamaica*, and ſeveral other Places in the warmer Parts of *America*; but are difficult to remove ſo as to have them grow in other Countries.

OPHRIS, Tway-blade.

The *Characters* are;

It hath a polypetalous anomalous Flower, conſiſting of ſix diſſimilar Leaves, of which the five upper ones are ſo diſpoſed, as to repreſent in ſome meaſure an Helmet, the under one being headed and ſhaped like a Man. The Empalement becomes a Fruit, perforated with three Windows, to which adhere Valves, pregnant with very ſmall Seeds like Duſt.

The *Species* are;

1. OPHRIS *bifolia. C. B. P.* Common Tway-blade.
2. OPHRIS *bifolia bulboſa. C. B. P.* Bulbous rooted Tway-blade.
3. OPHRIS *paluſtris, radice repente. Inſt. R. H.* Marſh Tway-blade, with a creeping Root.
4. OPHRIS *minima. C. B. P.* The leaſt Tway-blade.

The firſt Sort is pretty common in moiſt Meadows, and in ſhady moiſt Woods, in diverſe Parts of *England*: It flowers the latter End of *May*, and in the Beginning of *June*. This Plant may be tranſplanted into Gardens, if the Roots are taken up with a Ball of Earth, ſoon after the Leaves decay. Theſe muſt be planted in a moiſt ſhady Border, where, if they are not diſturbed, they will remain many Years, and require no other Care but to keep them clear from Weeds.

The ſecond Sort doth not grow wild in *England*, but is frequently found in *Germany*, and on the *Alpes*; this may be tranſplanted and managed as the former Sort.

The third Sort grows plentifully in ſeveral of the Northern Counties of *England*; and the fourth Sort grows in *Cambridgeſhire*, in *Hertfordſhire* and *Kent*. Theſe two Sorts delight in cold moiſt Places, ſo are with great Difficulty preſerved in Gardens.

OPULUS: The Gelder Roſe.

The *Characters* are;

The Leaves are like thoſe of the Maple-Tree: *The Flowers conſiſt of one Leaf, which expands in a circular Roſe Form, and is divided at the Top into five Parts; theſe are collected (for the moſt part) in Form of an Umbel, the largeſt of which grow on the Outſide, and are barren; but thoſe in the Middle are fruitful, producing red Berries, in each of which is contain'd one flat Heart-ſhap'd Seed.*

The *Species* are;

1. OPULUS *Ruelli.* Marſh Elder, *or* Gelder Roſe, with flat Flowers.
2. OPULUS *flore globoſo. Tourn.* The Gelder, *or* Gelderland Roſe.
3. OPULUS *flore globoſo, folio variegato.* The Gelder Roſe, with ſtrip'd Leaves.

The firſt of theſe Plants is very common in moiſt Woods in divers Parts of *England*, but is ſeldom cultivated in Gardens; though, if the Soil be moiſt in which this Tree be planted, it will afford a very agreeable Proſpect, both in the Seaſon when it is in Flower, and alſo in the Autumn when the Fruit is ripe, which generally grows in large Cluſters, and is of a beautiful red Colour: So that where a Wilderneſs or other Plantation of flowering Trees is deſign'd, and the Ground be moiſt, this and the next are two of the moſt proper Trees for ſuch Purpoſes; theſe thriving much better, and will produce their Flowers larger and in greater Quantities, than when they are placed in a dry Situation.

The ſecond Sort is very common in old Gardens in moſt Parts of *England*: This produces only barren Flowers, which being all very large, are produced in a globular Form, ſo that, at a Diſtance, they reſemble Snow-balls; whence the People in ſome Countries give it the Name of *Snow-ball Tree*. This Difference was at firſt accidental, as is the Caſe of all double Flowers which commonly ariſe from Seeds; and tho' theſe are not productive of Fruit, yet for the Sake of their Flowers they are much more eſteem'd than the ſingle Sort by the Gardeners.

The ſtrip'd Sort is alſo an Accident, occaſion'd by an Obſtruction of the Juices, as is the Caſe of all variegated Plants:

This is preſerv'd as a Curioſity by ſuch as are Lovers of ſtrip'd Trees and Plants, but muſt not be planted in a rich Soil, which would cauſe them to grow vigorouſly, whereby they would be in Danger of becoming plain again.

All theſe Sorts may be propagated either from Suckers or by laying down their Branches, which will take Root in a Year's time ; when they may be taken off from the old Plants, and tranſplanted either into a Nurſery, where they may be train'd up for two or three Years, or plac'd where they may remain for good. The beſt Time to remove theſe Trees, is at *Michaelmas*, as ſoon as their Leaves begin to decay, that they may be well rooted before the Drought of the next Spring comes on, which is often deſtructive to ſuch as have been newly tranſplanted, if they are not carefully attended with Water.

They are extremely hardy, and will endure the ſevereſt Cold of our moſt Northern Situations, and are only impatient of great Heat and Drought, ſo that they are very proper to plant in very cold Soils and Places which are greatly expos'd to the North Winds, where few other Shrubs will thrive ſo well. They will grow to the Height of twelve or fourteen Feet, and if reduc'd to regular Heads, are very ornamental during the Seaſon of Flowering ; and their Flowers are very proper to intermix with *Peonies* and other large Flowers, for Baſons and Flower-pots to adorn Halls and Chimnies. Their Seaſon of Flowering is in *May*, though their Flowers do ſometimes continue in Beauty a great Part of *June*, eſpecially if the Weather prove cool and moiſt.

OPUNTIA : [This Plant is call'd *Opuntia*, becauſe *Theophraſtus* writes, that it grows about *Opuntium*] The *Indian* Fig.

The *Characters* are ;

The Flower conſiſts of many Leaves, which expand in Form of a Roſe, *having a great Number of Stamina in the Center, which grow upon the Top of the Ovary ; the Ovary afterwards becomes a fleſhy umbilicated Fruit, with a ſoft Pulp, incloſing many Seeds, which are, for the moſt Part, angular.*

The *Species* are ;

1. OPUNTIA *vulgo herbariorum. J. B.* The Common *Indian* Fig of the Botaniſts.
2. OPUNTIA *minima, folio ſubrotundo. Tourn.* Leaſt *Indian* Fig, with roundiſh Leaves.
3. OPUNTIA *folio oblongo, media. Tourn.* Middle *Indian* Fig, with an oblong Leaf, *commonly called*, The Cochineal Fig-tree.
4. OPUNTIA *folio minori, rotundiori & compreſſiori. Tourn. Indian* Fig, with a ſmaller, rounder, and flatter Leaf.
5. OPUNTIA *major, validiſſimis ſpinis munita. Tourn.* The greater *Indian* Fig, armed with very ſtrong Prickles.
6. OPUNTIA *maxima, folio ſpinoſo, latiſſimo & longiſſimo. Tourn.* The largeſt *Indian* Fig, with a very broad and long prickly Leaf.
7. OPUNTIA *folio ſpinoſo, longiſſimo & anguſto. Tourn. Indian* Fig, with a very long, narrow, prickly Leaf.
8. OPUNTIA *latifolia, craſſiori folio, ſpinis albis numeroſis armato. Boerh. Ind. Indian* Fig, with a broad thick Leaf arm'd with many white Spines.
9. OPUNTIA *Curaſſavica minima. H. Beaum.* The ſmalleſt *Indian* Fig from *Curacao*, *commonly called*, The Pin-Pillow.
10. OPUNTIA *Americana, arbor excelſa, foliis reticulatis, flore flaveſcente. Plum. American Indian* Fig, which grows to be a tall Tree, with netted Leaves, and a yellowiſh Flower.
11. OPUNTIA *folio plano glabro ſcolopendriæ. Boerh. Ind. Indian* Fig, with a plain ſmooth Leaf, like Spleenwort.
12. OPUNTIA *maxima, folio oblongo-rotundo majore, ſpinulis obtuſis mollibus & innocentibus obſito, flore ſtriis rubris variegato. Sloan. Cat.* The greateſt *Indian* Fig, with greater oblong roundiſh Leaves, and ſmall ſoft blunt Spines, with a Flower ſtriped with Red.
13. OPUNTIA *major ſpinoſa cauleſcens, flore minore rubro clauſo, fructu parvo coccineo. Houſt.* Greater ſtalky and prickly *Indian* Fig, with a ſmaller red Flower, which doth not expand, and a ſmall ſcarlet Fruit.
14. OPUNTIA *cauleſcens, foliis ampliſſimis tenuibus compreſſis, ſpinis longiſſimis confertiſſimis, gracilibus & albicantibus, armatis. Houſt.* Stalky *Indian* Fig, with large narrow compreſſed Leaves, which are cloſely armed with very long ſlender white Spines.

The firſt of theſe Plants hath been a long Time in *England*, and is the moſt common Sort in *Europe* : This, Mr. *Ray* and Dr. *Robinſon* obſerv'd growing wild in the Kingdom of *Naples*, by the Sides of the Highways, on the Sides of the Mountains, and among Rocks in great Abundance ; but in theſe Northern Parts of *Europe*, it is generally preſerv'd in Green-houſes with other Exotick Plants ; tho' I have planted it under a warm Wall in a very dry Soil, where it has continu'd for ſeveral Years, and endured the ſevereſt of our Cold without any Cover, and has produc'd a greater Quantity of Flowers and Fruit than thoſe which were hous'd : So that the Cold is not ſo great an Enemy to this Plant as Wet, which if ſuffer'd to lie long upon it, or given in too large Quantities to the Root, will deſtroy it in a ſhort Time.

The other Sorts are much tenderer, being all of them Natives of the warm Parts of the *Weſt-Indies*. Theſe are ſome of them ſo tender as not to preſerv'd without the Aſſiſtance of a Stove (eſpecially the ninth and eleventh Sorts) in any tolerable Degree of Health ; for if they have not ſome additional Warmth to the Air of the Houſe in Winter, their Stems will ſhrivel and look yellowiſh and wither'd.

Theſe Plants may all be propagated by cutting off their Branches at the Joints, during any of the Summer Months ; which ſhould be laid in a warm dry Place for a Fortnight, that the wounded Part may be heal'd over, otherwiſe they will rot with the Moiſture which they imbibe at that Part, as is the Caſe with moſt other ſucculent Plants. The Soil in which theſe Plants are planted, ſhould be compos'd after the following Manner, *viz.* One third of light freſh Earth from a Paſture, a third Part Sea-ſand, and the other Part ſhould be one half rotten Tan, and the other half Lime-rubbiſh : Theſe ſhould be well mix'd, and laid in a Heap three or four Months before it be us'd, obſerving to turn it over at leaſt once a Month, that the ſeveral Parts may be well united ; then you ſhould paſs it thro' a rough Screen, in order to ſeparate the largeſt Stones and Clods, but by no means ſift it too fine, which is a very common Fault : Then you ſhould reſerve ſome of the ſmaller Stones and Rubbiſh to lay at the Bottom of the Pots, in order to keep an open Paſſage for the Moiſture to drain off ; which is what muſt be obſerv'd for all ſucculent Plants, for if the Moiſture be detain'd in the Pots, it will rot their Roots, and deſtroy the Plants.

When you plant any of the Branches of theſe Plants, you ſhould plunge the Pots into a moderate Hot-bed, which will greatly facilitate their taking Root : You ſhould alſo refreſh them now and then with a little Water, but be very careful not to let them have too much, or be too often water'd, eſpecially before they are rooted : When the Plants begin to ſhoot, you muſt give them a large Share of Air by raiſing the Glaſſes, otherwiſe their Shoots will draw up ſo weak as not to be able to ſupport themſelves ; and after they have taken ſtrong Root, you ſhould inure them to the Air by degrees, and then remove them into the Stove where they ſhould remain, placing them near the Glaſſes, which ſhould always be open'd in warm Weather, ſo that they may have the Advantage of a free Air, and yet be protected from Wet and Cold.

During the Summer-ſeaſon, theſe Plants will require to be often refreſh'd with Water, but it muſt not be given to them in large Quantities, leſt it rot them ; and in Winter they ſhould have very little Water given to them, but that ſhould be proportion'd to the Warmth of the Stove, for if the Air be kept very warm, they will require to be often refreſh'd, otherwiſe their Branches will ſhrink ; but if the Houſe be kept in a moderate Degree of Warmth, they ſhould have very little, for Moiſture at that Seaſon will rot them very ſoon.

The Heat in which theſe Plants thrive beſt is the temperate Point, as mark'd on Mr. *Fowler's Thermometers* ; for if they are kept too warm in Winter, it cauſes their Shoots to be very tender, and thereby very liable to decay if not duly attended. Thoſe Sorts which are inclinable to grow upright, ſhould have their Branches ſupported with Stakes, otherwiſe their Weight is ſo great, that it will break them down.

Theſe Plants are by moſt People expos'd to the open Air in the Summer-ſeaſon, but they thrive much better if they are continu'd in the Stoves, provided the Glaſſes be kept open, ſo that they may have free Air ; for when they are ſet abroad, the great Rains which generally fall in Summer, together with the unſettled Temper of the Air in our Climate, does greatly diminiſh their Beauty by retarding their Growth, and ſometimes in wet Summers they are ſo replete with Moiſture as to rot in the ſucceeding Winter ; nor will thoſe Plants which are ſet abroad, (I mean the tender Sorts) produce their Flowers and Fruit in ſuch Plenty as thoſe which are conſtantly preſerv'd in the Houſe.

The third Sort is ſuppos'd to be the Plant upon which the *Cochineal Fly* breeds : Theſe depoſite their Eggs in the Center of the Flowers, upon the Crown of the Ovary ; and when they are hatch'd, the young Inſects feed upon the Fruit, which is of a deep-red Colour within, and if eaten by Men, colours their Urine as red as Blood ; which has often frighted Strangers who have eaten of the Fruit, when they have thought it was real Blood which they voided, tho' there are no ill Effects attend it.

The ninth and eleventh Sorts are leſs common than the others, and are rarely ſeen but in very curious Gardens: Theſe are the tendereſt of them all, and ſhould be placed in a warm Part of the Stove in Winter, but muſt have very little Water given them at that Seaſon, and in Summer muſt always be kept in the Houſe, for they will not bear the open Air in the Heat of Summer, which is ſeldom very regular in this Country.

The twelfth Sort grows commonly to the Height of eight or nine Feet, has large Leaves, which are not prickly. The Flowers are ſtriped with Red, and the Fruit is not ſo palatable as moſt of the other Sorts. This is by many ſuppoſed to be the Sort which the Cochineel feeds on; but the third Sort is what the late Dr. Houſtoun brought from *La Vera Cruz*, with the Inſects upon it. This Sort hath very large yellow Flowers, and the Fruit, when ripe, is of a fine purple Colour, and ſmooth, having no Spines on the Outſide, which moſt of the other Sorts have.

The thirteenth Sort commonly grows to the Height of fifteen or ſixteen Feet, and hath a thick woody Stem. This grows very common on the Hills, and by the Road Sides in moſt Places in *Jamaica*.

The fourteenth Sort was obſerved in great Plenty near the Head of *Kingſtoun Harbour* in *Jamaica*, by the late Dr. *Houſtoun*, but without Flower or Fruit. This is by ſome Perſons called *Robinſon Cruſoe's Coat*, but for what Reaſon I cannot imagine.

The three laſt Sorts may be cultivated in the ſame Manner as hath been above directed, only obſerving to let theſe remain conſtantly in the Stove, otherwiſe they will not produce either Fruit or Flowers in this Country.

ORANGE. *Vide* Aurantium.

ORCHARD: In planting of an *Orchard*, great Care ſhould be had to the Nature of the Soil, that ſuch Sorts of Fruit as are adapted to grow upon the Ground intended to be planted, may be choſen, otherwiſe there can be little Hopes of their ſucceeding; and it is for want of rightly obſerving this Method, that we ſee in many Countries, *Orchards* planted which never arrive to any tolerable Degree of Perfection, their Trees ſtarving, and their Bodies are either cover'd with Moſs, or the Bark cracks and divides, both which are evident Signs of the Weakneſs of the Trees; whereas, if inſtead of *Apples*, the *Orchard* had been planted with *Pears*, *Cherries*, or any other Sort of Fruit to which the Soil had been adapted, the Trees might have grown very well, and produc'd great Quantities of Fruit.

As to the Poſition of an *Orchard*, (if you are at full Liberty to chooſe) a riſing Ground, open to the South-Eaſt, is to be preferr'd; but I would by no means adviſe to plant upon the Side of a Hill, where the Declivity is very great, for in ſuch Places the great Rains do commonly waſh down the better Part of the Ground, whereby the Trees would be depriv'd of proper Nouriſhment: But where the Riſe is gentle, it is of great Advantage to the Trees, by admitting the Sun and Air between them better than it can upon an intire Level, which is an exceeding Benefit to the Fruit, by diſſipating Fogs, and drying up the Damps, which when detain'd amongſt the Trees, do mix with the Air and render it rancid: If it be defended from the Weſt, North, and Eaſt Winds, it will alſo render the Situation ſtill more advantageous; for it is chiefly from thoſe Quarters that Fruit-Trees receive the greateſt Injury: Therefore, if the Place be not naturally defended from theſe by riſing Hills, (which is always to be preferr'd); then you ſhould plant large-growing Timber-Trees at ſome Diſtance from the *Orchard*, to anſwer this Purpoſe.

You ſhould alſo have a great Regard to the Diſtance of planting the Trees, which is what few People have rightly conſidered; for if you plant them too cloſe, they will be liable to Blights, and the Air being hereby pent in amongſt them, will cauſe the Fruit to be ill-taſted, having a great Quantity of damp Vapours from the Perſpiration of the Trees, and the Exhalations from the Earth mix'd with it, which will be imbib'd by the Fruit, and render their Juices crude and unwholſome.

Wherefore I can't but recommend the Method which has been lately practiſ'd by ſome particular Gentlemen with very good Succeſs; and that is, To plant the Rows of Trees fourſcore or a hundred Feet aſunder, and the Diſtance of the Trees in the Rows threeſcore Feet: The Ground between the Trees they plough and ſow with Wheat and other Crops, in the ſame manner as if it were clear from Trees, and they obſerve their Crops to be full as good as thoſe quite expos'd, (except juſt under each Tree when they are grown large and afford a great Shade); and by thus ploughing and tilling the Ground, the Trees are render'd more vigorous and healthy, ſcarcely ever having any Moſs or other Marks of Poverty, and will abide much longer, and produce better Fruit.

If the Ground in which you intend to plant an *Orchard* has been Paſture for ſome Years, then you ſhould plough in the *Green-ſward*, the Spring before you plant the Trees; and if you will permit to lie a Summer fallow, it will greatly mend it, provided you ſtir it two or three Times, to rot the Sward of Graſs, and prevent Weeds growing thereon.

At *Michaelmas* you ſhould plough it pretty deep, in order to make it looſe for the Roots of the Trees, which ſhould be planted thereon in *October*, provided the Soil be dry; but if it be moiſt, the Beginning of *March* will be a better Seaſon.

When you have finiſh'd planting the Trees, you ſhould provide ſome Stakes to ſupport them, otherwiſe the Wind will blow them out of the Ground; which will do them much Injury, eſpecially if they have been planted ſome Time; for the Ground at that Seaſon being warm, and for the moſt part moiſt, the Trees will very ſoon puſh out a great Number of young Fibres, which, if broken off by their being diſplaced, will greatly retard the Growth of them.

In the Spring following, if the Seaſon ſhould prove dry, you ſhould cut a Quantity of green Turf, which muſt be laid upon the Surface of the Ground about their Roots, turning the Graſs downward, which will prevent the Sun and Wind from drying the Ground, whereby the Expence of Watering will be ſav'd; and after the firſt Year they will be out of Danger, provided they have taken well.

Whenever you plough the Ground betwixt theſe Trees, you muſt be careful not to go too deep amongſt their Roots, leſt you ſhould cut them off, which would greatly damage the Trees; but if you do it cautiouſly, the ſtirring of the Surface of the Ground will be of great Benefit to them: Tho' you ſhould obſerve, never to ſow too near the Trees, nor ſuffer any great-rooting Weeds to grow about them, which would exhauſt the Goodneſs of the Soil, and ſtarve 'em.

If, after the Turf which was laid round the Trees be rotted, you dig it in gently about their Roots, it will greatly encourage them.

There are ſome Perſons who plant many Sorts of Fruit together in the ſame *Orchard*, mixing the Trees alternately: But this is a Method which ſhould always be avoided; for hereby there will be a very great Difference in the Growth of the Trees, which will not only render 'em unſightly, but alſo render the Fruit upon the lower Trees ill-taſted, by the tall ones over-ſhadowing them. So that if you are determin'd to plant ſeveral Sorts of Fruit on the ſame Spot, you ſhould obſerve to place the largeſt-growing Trees backward, and ſo proceed to thoſe of leſs Growth, continuing the ſame Method quite thro' the whole Plantation; whereby it will appear at a Diſtance in a regular Slope, and the Sun and Air will more equally paſs throughout the whole *Orchard*, that every Tree may have an equal Benefit therefrom.

The Soil of your *Orchard* ſhould alſo be mended once in two or three Years with Dung, or other Manure, which will alſo be abſolutely neceſſary for the Crops ſown between: So that where Perſons are not inclinable to help their *Orchards*, where the Expence of Manure is pretty great; yet as there is a Crop expected from the Ground beſides the Fruit, they will the more readily be at the Charge upon that Account.

In making Choice of Trees for an *Orchard*, you ſhould always obſerve to procure them from a Soil nearly akin to that where they are to be planted, or rather poorer; for if you have them from a very rich Soil, and that wherein you plant them is but indifferent, they will not thrive well, eſpecially for four or five Years after planting: So that 'tis a very wrong Practice to make the Nurſery, where young Trees are rais'd, very rich, when the Trees are deſign'd for a middling or poor Soil. The Trees ſhould alſo be young and thriving; for whatever ſome Perſons may adviſe to the contrary, yet it has always been obſerv'd, that tho' large Trees may grow and produce Fruit after being remov'd, they never make ſo good Trees, nor are ſo long-liv'd, as thoſe which are planted while young.

Theſe Trees, after they are planted out, will require no other pruning but only to cut out dead Branches, or ſuch as croſs each other ſo as to render their Heads confuſ'd and unſightly: The too often pruning them, or ſhortening their Branches, is very injurious, eſpecially to *Cherries* and Stone-Fruit, which will gum prodigiouſly, and decay in ſuch Places where they are cut: And the *Apples* and *Pears* which are not of ſo nice a Nature, will produce a greater Quantity of lateral Branches, which will fill the Heads of the Trees with weak Shoots whenever their Branches are thus ſhorten'd; and many Times the Fruit is hereby cut off, which, on many Sorts of Fruit-Trees, is firſt produc'd at the Extremity of their Shoots.

It may perhaps ſeem ſtrange to ſome Perſons, that I ſhould recommend the allowing ſo much Diſtance to the Trees in an *Orchard*, becauſe a ſmall Piece of Ground will admit of very few Trees when planted in this Method; but they'll pleaſe to obſerve, that when the Trees are grown up, they will produce a great deal more Fruit, than twice the Number when planted cloſe, and will be vaſtly better taſted; the Trees, when placed at a large Diſtance, being never ſo much in Danger of Blighting as in cloſe Plantations, as hath been obſerv'd in *Herefordſhire*, the great County for *Orchards*, where they find that *Orchards* ſo planted, or ſo ſituated, as that the Air is pent up amongſt the Trees, the Vapours which ariſe from the Damp of the Ground, and the Perſpiration of the Trees, collect the Heat of the Sun, and reflect it in Streams ſo as to cauſe what the call a *Fire-blaſt*, which is the moſt hurtful to their Fruits; and this is moſt frequent where the *Orchards* are open to the South-Sun.

But as *Orchards* ſhould never be planted, unleſs where large Quantities of Fruit are deſired, ſo it will be the ſame thing to allow twice or three times the Quantity of Ground; ſince there may be a Crop of Grain of any Sort upon the ſame Place as was before ſaid); ſo that there is no Loſs of Ground: And for a Family only it is hardly worth while to plant an *Orchard*; ſince a Kitchen-Garden well planted with Eſpaliers will afford more Fruit than can be eaten while good, eſpecially if the Kitchen-Garden be proportion'd to the Largeneſs of the Family: And if *Cyder* be required, there may be a large Avenue of *Apple-trees* extended croſs a neighbouring Field, which will render it pleaſant, and produce a great Quantity of Fruit; or there may be ſome ſingle Rows of Trees planted to ſurround Fields, *&c.* which will fully anſwer the ſame Purpoſe, and be leſs liable to the *Fire-blaſts* before-mentioned.

ORCHIS, ὄρχις a *Teſticle*, becauſe the Root of this Plant reſembles the Teſticles of a Man; or of ὀρέγω, *to have an Appetite after*, on account of its being a Provocative to Venery: It is alſo called κυνοσόρχις, of κύνος a *Dog*, and ὄρχις a *Teſticle.*] Satyrion or Fool-ſtones.

The *Characters* are;

It hath an anomalous Flower, conſiſting of ſix diſſimilar Leaves, the five uppermoſt of which are ſo diſpos'd as to imitate in ſome manner a Helmet; the under one being of many Shapes, headed for the moſt part, and tail'd, ſometimes repreſenting a naked Man, ſometimes a Butterfly, a Drone, a Pigeon, an Ape, a Lizard, a Parrot, a Fly, and other Things: but the Empalement afterwards becomes a Fruit divided into three Cells, in which are contain'd many ſmall Seeds. To theſe Notes ſhould be added, The Flowers are collected into a Spike; and the Roots are fleſhy, ſometimes roundiſh and double like Teſticles, ſometimes flat, and in a manner ſhap'd like a Hand.

The *Species* are;

1. ORCHIS *morio mas, foliis maculatis. C. B. P.* The Male Fool-ſtones.
2. ORCHIS *morio fœmina. Park. Theat.* The Female Fool-ſtones.
3. ORCHIS *barbata fœtida. J. B.* The Lizard Flower, or Great Goat-ſtones.
4. ORCHIS *Pannonica.* 4 *Cluſ. Hiſt.* Little Purple-flower'd Orchis.
5. ORCHIS *obſcure purpurea odorata. Tourn.* Sweet-ſmelling dark-purple Orchis.
6. ORCHIS *purpurea ſpica congeſta pyramidali. Raii Syn.* Purple late-flowering Orchis.
7. ORCHIS *odorata moſchata ſive monorchis. C. B. P.* The yellow ſweet or Muſk Orchis.
8. ORCHIS *ſpiralis alba odorata. J. B.* Triple Ladies Traces.
9. ORCHIS *latifolia, hiante cucullo major. Tourn.* The Man Orchis.
10. ORCHIS *anthropophora Orcades. Col. Ec.* Man Orchis, with a ferrugineous, and ſometimes a green Colour.
11. ORCHIS *myodes, galea & alis herbidis. J. B.* The common Fly Orchis.
12. ORCHIS *myodes major. Park. Theat.* The Greater Fly Orchis.
13. ORCHIS *fuſciflora, galea & alis purpuraſcentibus. J. B.* The Common Humble Bee Satyrion, or Bee-flower.
14. ORCHIS *ſive Teſticulus Sphegodes hirſuto flore. J. B.* Humble Bee Satyrion, with green Wings.
15. ORCHIS *hermaphroditica bifolia. J. B.* Butter-fly Satyrion.
16. ORCHIS *alba bifolia minor, calcari oblongo. C. B. P.* The Leſſer Butter-fly Satyrion.
17. ORCHIS *palmata pratenſis latifolia, longis calcaribus. C. B. P.* The Male-handed Orchis, or Male Satyrion Royal.
18. ORCHIS *palmata pratenſis maculata. C. B. P.* The Female-handed Orchis, or Female Satyrion Royal.
19. ORCHIS *palmata minor, calcaribus oblongis. C. B. P.* Red-handed Orchis, with long Spurs.
20. ORCHIS *palmata minor, flore luteo-viridi. Raii Syn.* Handed Orchis, with a greeniſh Flower, *by ſome call'd* The Frog Orchis.

All theſe Sorts of *Orchis* grow wild in ſeveral Parts of *England*; but, for the extreme Oddneſs and Beauty of their Flowers, deſerve a Place in every good Garden: And the Reaſon for their not being cultivated in Gardens, proceeds from their Difficulty to be tranſplanted: Tho' this, I believe, may be eaſily overcome, where a Perſon has an Opportunity of marking their Roots in their Time of flowering, and letting them remain until their Leaves are decay'd, when they may be tranſplanted with Safety: For it is the ſame with moſt Sorts of bulbous or fleſhy-rooted Plants, which, if tranſplanted before their Leaves decay, ſeldom live, notwithſtanding you preſerve a large Ball of Earth about them; for the extreme Part of their Fibres extend to a great Depth in the Ground, from whence they receive their Nouriſhment; which if broken or damag'd by taking up their Roots, they ſeldom thrive after; for tho' they may ſometimes remain alive a Year or two, yet they grow weaker, until they quite decay: ſo that whoever would cultivate them, ſhould ſearch them out in their Seaſon of flowering, and mark 'em; and when their Leaves are decay'd the Roots ſhould be taken up, and planted in a Soil and Situation as nearly reſembling that wherein they naturally grow as poſſible, otherwiſe they will not thrive: So that they cannot be plac'd all in the ſame Bed; for ſome are only found upon chalky Hills, others in moiſt Meadows, and ſome in ſhady Woods, or under Trees: But if their Soil and Situation be adapted to their various Sorts, they will thrive and continue ſeveral Years, and, during their Seaſon of flowering, will afford as great Varieties as any Flowers which are at preſent cultivated.

The firſt Sort flowers in *April*, and is very common in Paſtures and buſhy Places in moſt Parts of *England*.

The ſecond Sort flowers in *May*: This is common in Paſtures almoſt every-where.

The third Sort is more rare than the former: This is found in a Lane near *Dartford* in *Kent*, and is one of the largeſt of all the Kinds: It flowers at the Latter-End of *May*.

The fourth Sort grows upon dry barren Hills, particularly between *Northfleet* and *Graveſend*: This flowers at the Latter-end of *April*.

The fifth Sort is found in great Plenty in *Weſtmorland*, but particularly in the Meadows, upon both the Banks of *Eden*, throughout ſeveral Pariſhes: It flowers in *May*.

The ſixth Sort grows upon dry, barren, or chalky Hills in divers Parts of *England*: This flowers in *June*.

The ſeventh Sort grows upon chalky Hills, but is pretty rare; it is particularly found upon the Hills near *Cawſham* in *Berkſhire*, and upon *Gogmagog* Hills in *Cambridgeſhire*: It flowers in *May*.

The eighth Sort flowers in *Auguſt*: This grows upon dry ſtony Places, as alſo in moiſt Paſtures in the North Parts of *England*.

The ninth Sort grows upon *Cawſham* Hills, as alſo upon the dry Banks on the Road-ſide between *Greenhith* and *Northfleet* in *Kent*; and flowers in *May*.

The tenth Sort is found about *Northfleet* with the former, and flowers about the ſame Time, as doth alſo the eleventh and twelfth.

The thirteenth Sort flowers in *June*: This grows upon dry Places in many Parts of *England*, as doth the fourteenth Sort, which flowers in *April*.

The fifteenth and ſixteenth Sorts grow in ſhady Places in divers Parts of *England*: They both flower in *May*.

The ſeventeenth and eighteenth Sorts grow in moiſt Paſtures very plentifully; the firſt flowering in *May*, the other in *June*.

The nineteenth Sort grows in moiſt Paſtures, and flowers in *June*.

The twentieth Sort grows in dry Paſtures, and flowers in *May*.

Thus having mention'd the ſeveral Places of Growth, and the Times of theſe Plants flowering, it will be no very difficult Taſk for a Perſon to ſearch them out; which, if it happens to be in a Place where the Roots may be mark'd, and taken up after their Leaves are decay'd, (as I ſaid before) there will be little Hazard of their ſucceeding: But if you are oblig'd to take 'em up in Flower, you muſt be very careful to preſerve a much Earth as poſſible to their Roots, otherwiſe there can be little Hopes of their living. Nor ſhould they be kept out of the Ground longer than till you can conveniently get them Home; for if the Air dries the Earth about 'em, they will ſhrink, and be good for nothing; and if the Earth be water'd, the Roots of ſuch as grow upon dry Soils will rot and periſh; therefore you ſhould be very careful in this Particular.

OREOSELINUM, Mountain Parſley.

The *Characters* are;

It hath a roſe-ſhaped umbellated Flower, conſiſting of ſeveral Leaves, placed in a circular Order, reſting on the Empalement, which afterward becomes a Fruit, compoſed of two Seeds, which are oval, plain, large-ſtreaked and bordered, and ſometimes caſt off their Cover. To theſe Notes muſt be added, That the Leaves are like Parſley.

The *Species* are;

1. Oreoselinum *apii folio, majus. Inſt. R. H.* Greater Mountain Parſley, with a parſley Leaf.

2. Oreoselinum *apii folio, minus. Inſt. R. H.* Smaller Mountain Parſley, with a parſley Leaf.

3. Oreoselinum *pratenſe, cicutæ folio. Inſt. R. H.* Meadow Mountain Parſley, with a hemlock Leaf.

4. Oreoselinum *Orientale, ſeſeleos Maſſilienſis folio. Tourn. Cor.* Eaſtern Mountain Parſley, with a Leaf like the Hartwort of *Marſeilles*.

The firſt and ſecond Sorts grow in the mountainous Paſtures, and Vineyards on the *Rhine* in *Germany*, as alſo on the Hills in the Neighbourhood of *Geneva*.

The third Sort grows in the Meadows, and low Paſtures, in ſeveral Parts of *Germany*, but particularly in the *Palatinate*.

The fourth Sort was diſcovered by Dr. *Tournefort* in the *Levant*, from whence he ſent the Seeds to the Royal Garden at *Paris*.

The Seeds and Roots of the two firſt Sorts are commonly uſed in Medicine by the Phyſicians of *Germany*, but are never preſcribed in *England*. They are eſteemed cleanſing and opening, and very good for the Stone and Gravel. From ſome Species of this Genus, Dr. *Boerhaave* conjectures that ſome of the Gums of *Aſia* and *Africa* are produced: as the *Ammoniac*, *Sagapenum*, *Opopanax*, and *Galbanum*.

Theſe Plants are propagated by Seeds, which ſhould be ſown in Autumn, as ſoon as poſſible after they are ripe; for if they are kept out of the Ground until the Spring, they ſeldom grow. Theſe Seeds ſhould be ſown in the Places where they are deſigned to remain; for as they have downright carroty Roots, ſo they do not bear tranſplanting well. They require a moiſt light Soil, and thrive beſt in a ſhady Situation. The beſt Method is, to ſow the Seeds in Rills, which ſhould be made about eighteen Inches aſunder, and about half an Inch deep. In the Spring, when the Plants come up, they ſhould be carefully cleared of Weeds; and where the Plants are too cloſe, they ſhould be thinned, leaving them about ſix or ſeven Inches apart, that they may have room to grow; but the firſt Sort ſhould be allowed a greater Share of Room, becauſe it grows very large, often riſing to the Height of ſix or ſeven Feet, and ſpreads its Leaves near two Feet each way.

In two Years after the Seeds are ſown, the Plants (if they have thriven well) will be ſtrong enough to produce their Flower-ſtems, when they will begin to ſhoot up in *April*, and their Flowers will appear in *June*, but their Seeds will not ripen till the End of *Auguſt* or *September*. Theſe Plants will continue ſome Years, and will annually produce Seeds; ſo the Ground ſhould be carefully dug between the Plants every Spring, and conſtantly kept clean from Weeds, which is all the Culture the Plants will require.

ORIGANUM, [of 'Ορίγανον, of ὄρος a *Mountain*, and γάνυμαι to *rejoyce*, q. d. a *Plant that delights to grow upon Mountains.*] Origany, or Baſtard Marjoram.

The *Characters* are;

It hath a labiated Flower, conſiſting of one Leaf, whoſe Upper Lip is erect, roundiſh, and divided into two; but the Under Lip is cut into three Segments: Out of the Flower-cup ariſes the Pointal, attended, as it were, by four Embryo's, which afterward become ſo many roundiſh Seeds inclos'd in the Flower-cup: To which ſhould be added, The Flowers grow in ſcaly Spikes, ſomewhat reſembling thoſe of the Muſcary.

The *Species* are;

1. Origanum *vulgare ſpontaneum. J. B.* Wild Marjoram.

2. Origanum *onites. C. B. P.* Pot Marjoram.

3. Origanum *heracleoticum cunila gallinacea Plinii. C. B. P.* Winter Sweet Marjoram, *vulgo*.

4. Origanum *ſylveſtre humile. C. B. P.* Dwarf wild Origany.

5. Origanum *ſylveſtre, foliis variegatis. Hort. Ed.* Wild Marjoram, with variegated Leaves.

6. Origanum *Orientale, folio brunellæ glauco, flore albo. Vaill.* Oriental Wild Marjoram, with a Self-heal Leaf, and white Flowers.

There are ſeveral other Species of this Plant preſerv'd in curious Botanick Gardens, for Variety: But as they are never propagated for Uſe, ſo I ſhall not enumerate them in this Place.

The firſt Sort here mention'd grows wild upon dry chalky Hills, and on gravelly Soils, in divers Parts of *England*, and is gather'd by the People who ſupply the Markets with Medicinal Herbs; ſo that it is rarely cultivated in Gardens.

The ſecond Sort was formerly more cultivated than at preſent: This was us'd as a Pot-herb for Soups, &c. but of late Years it has been almoſt neglected: It is ſaid to grow wild in ſome Parts of *England*.

The third Sort has the Appearance of common *Sweet Marjoram*; and having a ſweet Smell, is cultivated in many Gardens near *London*, and brought to the Markets to ſupply the Want of *Sweet Marjoram* early in the Seaſon, before the *Marjoram* (which is an annual Plant) can be procured, and is us'd by the People who make up Noſegays.

The fourth and fifth Sorts are preſerv'd as Varieties by ſome People, who uſe the fourth, many times, as a Pot-herb, inſtead of the ſecond.

The ſixth Sort was brought from the *Levant*, but is hardy enough to endure the ſevereſt Cold of our Climate in the open Air, provided it be planted upon a dry Soil.

Theſe Plants may be all propagated by ſowing their Seed in the Manner directed for *Marjoram*, and the Plants ſhould be treated in the ſame Way, therefore I ſhall forbear repeating it in this Place: They may alſo be propagated by parting their Roots, or planting Cuttings in the Spring, which, if water'd and ſhaded, will take Root in a few Days, and multiply exceedingly.

Their Roots will abide ſeveral Years, and require no farther Culture but to keep them clear from Weeds, and tranſplant them every Year, otherwiſe they will grow ſo large as to rot in the Middle for want of Air.

ORNITHOGALUM, ['Ορνιθόγαλον, of ὄρνις a *Bird*, and γάλα *Milk*, i. e. a Plant whoſe Flowers are as white as the white Plumes of feather'd Animals.] Star of Bethlehem.

The *Characters* are;

It hath a Lily Flower, compoſed of ſix Petals (or Leaves) ranged circularly, whoſe Center is poſſeſs'd by the Pointal, which afterwards turns to a roundiſh Fruit, which is divided into three Cells, and fill'd with roundiſh Seeds: To which muſt be added, It hath a bulbous or tuberoſe Root, in which it differs from Spiderwort.

The *Species* are;

1. Ornithogalum *anguſtifolium majus, floribus ex albo vireſcentibus. C. B. P.* Spiked Star of Bethlehem, with a greeniſh Flower.

2. Ornithogalum *umbellatum medium anguſtifolium. C. B. P.* Common Star of Bethlehem.

3. Ornithogalum *luteum. C. B. P.* Yellow Star of Bethlehem.

4. Ornithogalum *majus ſpicatum, flore albo. C. B. P.* The Great White Star of Bethlehem.

5. Ornithogalum *Neapolitanum. J. B.* Star of Naples, *vulgo*.

6. Ornithogalum *anguſtifolium ſpicatum maximum. C. B. P.* The greateſt narrow-leaved ſpiked Star of Bethlehem.

7. Ornithogalum *ſpicatum ſeu comoſum, flore lacteo. C. B. P.* Spiked or branchy Star of Bethlehem, with a milk-white Flower.

8. Ornithogalum *majus ſpicatum alterum. C. B. P.* Another great ſpiked Star of Bethlehem, commonly called the Star of *Conſtantinople*.

9. Ornithogalum *ſpicatum, flore viridi lacteſcente. C. B. P.* Spiked Star of Bethlehem, with a whitiſh green Flower.

10. Ornithogalum *ſpicatum album. C. B. P.* White ſpiked Star of Bethlehem.

11. Ornithogalum *luteum ſive pallidum majus. C. B. P.* Greater yellow or pale Star of Bethlehem.

12. Ornithogalum *luteum, magno flore. C. B. P.* Yellow Star of Bethlehem, with a large Flower.

13. Ornithogalum *luteum minus. C. B. P.* Smaller yellow Star of Bethlehem.

14. Ornithogalum *Luſitanicum, capillaceo folio, luteum. Inſt. R. H.* Yellow *Portugueſe* Star of Bethlehem, with a capillaceous Leaf.

15. ORNITHOGALUM *ſpicatum unifolium, flore niveo odorato. Vir. Luſit.* Spiked Star of Bethlehem, with one Leaf, and a ſweet-ſmelling ſnowy Flower.

16. ORNITHOGALUM *umbellatum maximum. C. B. P.* The greateſt umbellated Star of Bethlehem, commonly called the Star of *Alexandria.*

17. ORNITHOGALUM *umbellatum majus anguſtifolium. C. B. P.* Greater narrow-leaved Star of Bethlehem, with umbellated Flowers.

18. ORNITHOGALUM *umbellatum album medium latifolium. C. B. P.* White middle broad-leaved umbellated Star of Bethlehem.

19. ORNITHOGALUM *album minus. C. B. P.* Smaller white Star of Bethlehem.

20. ORNITHOGALUM *umbellatum, floſculis ex albo ſubcæruleis. C. B. P.* Umbellated Star of Bethlehem, with whitiſh blue Flowers.

21. ORNITHOGALUM *latifolium & maximum. C. B. P.* The greateſt broad-leaved Star of Bethlehem.

22. ORNITHOGALUM *latifolium alterum. C. B. P.* Another broad-leaved Star of Bethlehem.

23. ORNITHOGALUM *Orientale villoſum, flore luteo magno. Tourn. Cor.* Eaſtern hairy Star of Bethlehem, with a large yellow Flower.

24. ORNITHOGALUM *Samium villoſum umbellatum album. Tourn. Cor.* Hairy white umbellated Star of Bethlehem of *Samos.*

25. ORNITHOGALUM *Africanum luteum odoratum, foliis cepaceis, radice tuberoſo. H. L.* Yellow ſweet-ſmelling *African* Star of Bethlehem, with Onion Leaves, and a tuberoſe Root.

The firſt five Sorts are propagated by Off-ſets, which their Roots do commonly produce in great Plenty. The beſt Time to tranſplant their Roots is in *July*, when their Leaves are decay'd; for if they be removed late in Autumn, their Fibres will be ſhot out, when they will be very apt to ſuffer, if diſturb'd. They ſhould have a light ſandy Soil; but it muſt not be overdung'd, which would cauſe their Roots to decay. They may be intermix'd with other bulbous-rooted Flowers in the Borders of the Pleaſure-Garden, where they will afford an agreeable Variety, and continue in Flower a long Time. Their Roots need not be tranſplanted oftener than every other Year; for if they be taken up every Year, they will not increaſe ſo faſt; but when they are ſuffer'd to remain too long unremov'd, they will have ſo many Off-ſets about them as to weaken their blowing Roots. Theſe may alſo be propagated from Seeds, which ſhould be ſown and managed as moſt other bulbous-rooted Flowers, and will produce their Flowers in three or four Years after ſowing.

The ſixth, ſeventh, eighth, ninth, tenth, eleventh, twelfth, thirteenth, fourteenth, and fifteenth Sorts, are all of them very hardy, and may be propagated by Off-ſets, which are ſent out from their Roots in great Plenty. They grow wild in *Spain*, *Portugal*, and *Italy*, from whence their Roots have been obtained by thoſe Perſons who are curious in collecting of Flowers.

The five following Sorts are alſo very hardy, and may be treated as the former; theſe produce their Flowers in form of an Umbrella, on the Top of their Stalks, whereas the other Sorts grow on Spikes. They are all of them very pretty Flowers, and are proper to adorn the open Borders of the Flower-Garden, becauſe they require very little Care to preſerve them, and make an agreeable Variety when they are intermixed with other hardy Flowers.

The firſt, ſecond, and third Sorts grow wild in ſeveral Places in the North of *England*, from whence their Roots may be procured. Theſe will thrive very well in ſhady Borders, and do require a pretty ſtrong Soil, in which they will flower much ſtronger, than when they are planted in a rich warm Soil.

The fifth Sort is the leaſt to be valued of all the Kinds; for the Flowers are large, and have no Beauty; and ſo ſoon as the Seed-veſſels begin to ſwell, their Weight breaks down the Stalks; ſo that where they are not ſupported with Sticks, they fall to the Ground, and make a bad Appearance. This Sort ſends forth ſuch Numbers of Off-ſets, that when it hath been a very few Years an Inhabitant in any Garden, it will be very difficult to root out again, ſo that it ſhould never have room in the Borders amongſt other valuable Flowers. *Cluſius*, in his Hiſtory of Plants, ſays, he never ſaw one of them in Flower, unleſs the Root was brought freſh from *Conſtantinople*; for he obſerves, that unleſs the Root have conceived a Flower in the Womb, they will never produce any, when they are tranſplanted to colder Countries.

The ſixteenth Sort is very common in many Gardens near *London*, but it rarely produces any Flowers. This multiplies very faſt by Off-ſets, ſo as in few Years to ſtock a whole Garden. The Leaves and Bulbs, of this Plant are very like to thoſe of the Hyacinth of *Peru*, ſo that many Perſons have taken it for one of that Kind. Theſe Roots have been brought over from *Italy* in great Plenty of late Years, by the Perſons who import Orange-trees; but I have not yet heard that any of them have produced Flowers in *England.*

The twenty-firſt, twenty-ſecond, twenty-third, and twenty-fourth Sorts, are as yet very rare in *England:* Theſe grow in the *Archipelago*; and I have been informed by a very curious Gentleman, that they grow in great Plenty in the *Iſland* of *Zant*, from whence their Roots may be eaſily obtained, by the Ships that bring over the Currans. The beſt Method to bring them over, would be to have the Roots taken out of the Ground, ſoon after their Flower-ſtems and Leaves decay, and dry them in a ſhady Place. Then they may be hung up in the Ship, in Nets, (as is practiſed for Onions) to prevent their rotting by Moiſture, and to ſecure them from Vermin: and if they are four Months or longer out of the Ground, they will do very well, provided the Roots are ſound.

All theſe Sorts may be cultivated by Seeds, by which Method there may be ſome new Varieties obtained; but there are very few Perſons who are curious to propagate them this way, becauſe they multiply ſo faſt by Off-ſets. But whoever is willing to try this Method, they may follow the Directions given for raiſing Narciſſus's.

The twenty-fifth Sort was formerly more common in the *Engliſh* Gardens than at preſent. This Kind is more tender than either of the former; ſo ſhould be planted in Pots filled with freſh light Earth, and in Winter muſt be placed in an airy Glaſs-caſe, amongſt Sedums, Ficoides's, and ſuch other pretty hardy ſucculent Plants, which require a large Share of Air in mild Weather; and in Summer they may be removed out of the Houſe, and placed in a warm ſheltered Situation; obſerving never to give theſe Plants much Water when they are not in a growing State, leſt it rot their Roots; but when they are growing freely, they muſt be frequently refreſhed with Water. Theſe Roots ſhould be tranſplanted every Year; the beſt Time to perform this Work, is ſoon after their Flower-ſtems are decayed, when the Roots will be in the moſt inactive State. When this is done, the Off-ſets ſhould be carefully taken off, and each tranſplanted into a ſeparate ſmall Pot filled with light freſh Earth, and may be treated as the old Roots.

ORNITHOPODIUM, [of ὄρνις a *Bird*, and ποῦς ποδὸς a *Foot*, becauſe the Huſk of this Plant reſembles the Foot of a ſmall Bird.] Bird's-Foot.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a hooked jointed Pod, for the moſt part waved, containing in each Joint one roundiſh Seed: To which muſt be added, That ſeveral Pods grow together in ſuch a manner as to reſemble the Foot of a Bird.

The *Species* are;

1. ORNITHOPODIUM *radice tuberculis nodoſa. C. B. P.* Bird's-Foot, with a knobbed Root.

2. ORNITHOPODIUM *majus. C. B. P.* The Greater Bird's-Foot.

3. ORNITHOPODIUM *ſcorpioides, ſiliqua compreſſa. Tourn.* Caterpillar Bird's-Foot, with a flat Pod.

4. ORNITHOPODIUM *portulacæ folio. Tourn.* Bird's-Foot, with a Purſlane Leaf.

Theſe Plants are propagated by ſowing their Seeds in the Spring upon a Bed of light freſh Earth, where they are to remain; (for they ſeldom do well when they are tranſplanted); and when the Plants come up, they muſt be carefully clear'd from Weeds; and where they are too cloſe, ſome of the Plants ſhould be pull'd out, ſo as to leave the remaining ones about ten Inches aſunder. In *June* theſe Plants will flower, and the Seeds will ripen in *Auguſt*. There is no great Beauty in them; but, for the Variety of their jointed Pods, they are preſerv'd by ſome curious Perſons in their Pleaſure-Gardens; where, if their Seeds be ſown in Patches in the Borders, each Sort diſtinctly by itſelf, and the Plants thinn'd, leaving only two at each Patch, they will require no farther Care; and will add to the Variety, eſpecially where the *Snail* and *Caterpillar* Plants are preſerv'd, which are very proper to intermix with them. They are all annual Plants, which periſh ſoon after their Seeds are ripe.

OROBUS, [ὄροβος, of ἐρέπτω to *eat*, and βοῦς an *Ox*, q. d. an Herb with which *Oxen* are fed, becauſe the Antients us'd to fatten their *Oxen* with a like Herb] Bitter Vetch.

The *Characters* are;

It hath a papilionaceous Flower, conſiſting of the Standard, the

the Keel, and the Wings ; out of whoſe Empalement riſes the Pointal wrapt up in the Membrane, which afterward becomes a round Pod, full of Oval-ſhap'd Seeds : To which muſt be added, That two Leaves join'd together grow upon a Rib that ends in a Point.

The *Species* are ;

1. Orobus *ſylvaticus purpureus vernus. C. B. P.* Vernal Purple-Wood Bitter-Vetch.

2. Orobus *ſylvaticus noſtras. Raii Syn.* Engliſh Wood Bitter-Vetch.

3. Orobus *ſylvaticus, foliis oblongis glabris. Tourn.* Wood or Heath Peas.

4. Orobus *ſylvaticus, foliis viciæ. C. B. P.* Wood Orobus, with Vetch-Leaves.

5. Orobus *latifolius repens, ſiliqua parva. Boerh. Ind.* Broad-leav'd creeping Orobus, with a ſmall Pod, *commonly call'd,* Venetian Vetch.

6. Orobus *ſylveſtris anguſtifolius, aſphodeli radice. C. B. P.* Narrow-leaved wild Bitter-vetch, with an aſphodel Root.

7. Orobus *ſylvaticus, foliis nervoſis. Inſt. R. H.* Wild or wood Bitter-vetch, with Leaves full of Nerves.

8. Orobus *Creticus latifolius incanus. Inſt. R. H.* Broad-leaved hoary Bitter-vetch of Candy.

9. Orobus *Orientalis latifolius villoſus, flore croceo. Tourn. Cor.* Broad-leaved hairy Eaſtern Bitter-vetch, with a ſaffron-coloured Flower.

10. Orobus *Americanus, fructu coccineo, nigrâ maculâ notato. Inſt. R. H.* American Bitter-vetch, with ſcarlet Fruit, mark'd with a black Spot, commonly called wild Liquorice by the Inhabitants of America.

11. Orobus *Americanus erectus, foliorum pinnis anguſtis & ſubtus incanis, ſiliquis glabris. Houſt.* Upright *American* Bitter-vetch, with narrow Leaves, which are hoary underneath, and ſmooth Pods.

12. Orobus *Americanus latifolius argenteus, flore purpureo. Houſt.* Broad-leaved ſilvery American Bitter-vetch, with a purple Flower.

13. Orobus *Americanus procumbens & hirſutus, flore purpureo. Houſt.* Trailing hairy American Bitter-vetch, with a purple Flower.

14. Orobus *Americanus procumbens minimus anguſtifolius, flore coccineo. Houſt.* The leaſt narrow-leaved trailing Bitter-vetch of America, with a ſcarlet Flower.

The firſt of theſe Plants was brought from *Germany,* where it grows in the Foreſts in great Plenty, as alſo about *Geneva,* but it is hardy enough to endure the Cold of our Climate in the open Air, provided it be planted in a dry Soil. This may be propagated either from Seeds or by parting the Roots in the Spring. If you ſow the Seeds, you ſhould obſerve to put them pretty early into the Ground before the dry Weather comes on, otherwiſe the Seeds will not come up : As you ſhould alſo tranſplant the Roots juſt before they begin to ſhoot, or elſe their Flowers will be very weak. The Roots of this Plant will abide many Years, and ſpring up freſh every Year, and in *April* produce fine Spikes of purple Pea-bloom Flowers, which are ſucceeded by ſtrait black Pods two Inches long, containing ſeveral roundiſh bitter Seeds.

The ſecond and third Sorts grow wild in Woods and ſhady Places in divers Parts of *England,* where, during their Seaſon of Flowering, they make a handſome Appearance ; and when tranſplanted under Hedges in a Garden, they will thrive extreamly well, and produce great Quantities of Flowers every Spring.

Theſe were formerly recommended by Dr. *Liſter,* to be ſown for Fodder, as a great Improvement ; but I believe them not very proper for that Purpoſe, ſince they ſeldom thrive well when expos'd to the Sun, nor will they ever riſe to any conſiderable Height, their Branches trailing upon the Ground, unleſs they are ſupported, ſo that in a wet Seaſon they would be apt to rot.

The fourth Sort riſes to be two or three Feet high, and hath ſtrong upright Stalks ; upon which, in *May,* are produc'd great Quantities of purple Flowers, which are ſucceeded by long ſtrait Pods, containing oblong bitter Seeds. The Root of this Plant will abide many Years ; the Stalks decaying in Winter, but do ſpring up again the ſucceeding Year : It delights in a dry freſh Soil, and deſerves a Place in large Borders under the Shade of Trees, where it will thrive well, and make a handſome Appearance.

The fifth Sort was formerly preſerv'd in the Green-houſe as a tender Plant, but will endure the Cold of our Climate very well, if planted in a dry Soil ; and thoſe Roots which are planted in the full Ground, will produce much ſtronger Flowers than thoſe preſerv'd in Pots. This Plant flowers in *April,* but ſeldom produces good Seeds in this Country.

The firſt five Sorts may be propagated either from Seeds, or by parting of their Roots, in the manner directed for the firſt Sort ; and if rightly diſpos'd in the Borders of a Garden, do afford an agreeable Variety : And ſince they are hardy, requiring but little Culture, they deſerve a Place in every good Garden.

The ſixth, ſeventh, eighth, and ninth Sorts are very hardy Plants : theſe may be propagated by ſowing of their Seeds in the Spring, on a Border of freſh Earth, expoſed only to the Morning Sun ; and when the Plants come up, they ſhould be carefully cleared from Weeds, and thinned where they are too cloſe. The *Michaelmas* following, they ſhould be taken up and tranſplanted where they are deſigned to remain, which ſhould be in a ſhady Place, or under Trees in wilderneſs Quarters, where theſe Plants will thrive exceeding well, and when they flow in the Spring, will make an agreeable Variety, in ſuch Places where better Plants will not live, which renders them worthy of a Place in large Gardens.

The tenth Sort is very common in the warmeſt Parts of *America, Aſia,* and *Africa.* The Seeds of this Sort are frequently brought to *England* from the *Weſt-Indies* for their Beauty ; being round and hard, and of a bright ſcarlet Colour, with a black Eye, and are ſomewhat leſs than Peas. Theſe Seeds are by the Inhabitants of the Countries, where they naturally grow, ſtrung, and wore about their Necks for Ornament. And the Leaves of the Plant are ſometimes uſed inſtead of Liquorice, being eſteemed good for the dry Gripes.

This Plant twiſts itſelf round whatever Trees or Shrubs grow near it, and will riſe to the Height of ten or twelve Feet, and will continue ſeveral Years. The Flowers are produced on ſlender Foot-ſtalks, growing in a cloſe Spike or Bunch, which are ſhaped like thoſe of the Kidney-bean, and are of a pale purple Colour ; theſe are ſucceeded by ſhort thick Pods, in which are contained the Seeds.

The eleventh Sort was diſcovered by the late Dr. *Houſtoun* in *Jamaica,* and the twelfth, thirteenth, and fourteenth Sorts, were diſcovered by the ſame Gentleman, at *La Vera Cruz* in the *Spaniſh Weſt-Indies.* Theſe five laſt-mentioned Sorts, being Natives of warm Countries, are very tender ; ſo muſt be preſerved in Stoves, otherwiſe they will not live in *England.* Theſe are propagated by Seeds, which ſhould be ſown early in the Spring, in ſmall Pots, filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, obſerving frequently to moiſten the Earth, otherwiſe the Seeds will not grow (eſpecially thoſe of the tenth Sort, which are very hard, and will ſometimes remain a whole Seaſon in the Ground, where they are kept dry). When the Plants come up, they ſhould be carefully taken out of the Pots, and each tranſplanted into ſeparate ſmall Pots, filled with rich Earth, and then plunged again into the Tan-bed, obſerving to ſhade them until they have taken Root ; after which Time they ſhould have freſh Air admitted to them every Day in warm Weather, and muſt be frequently water'd. With this Management the Plants will make a great Progreſs, and in a few Weeks thoſe of the tenth Sort will reach the Glaſſes of the Hot-bed, unleſs the Frame be very high ; ſo theſe ſhould then be taken out, and plunged into the Bark-bed in the Stove, where they may have room to grow. Theſe Plants ſhould be ſupported by Sticks, or placed near a Trellaſe, to which they ſhould be faſtened, otherwiſe they will trail about whatever Plants grow near them.

The other Sorts being of humbler Growth, may be kept in the Hot-bed until *Michaelmas,* when the Nights begin to be cold ; at which Time they ſhould be removed into the Stove, and plunged into the Bark-bed, where they muſt be treated as other tender exotick Plants ; by which Method they may be preſerved thro' the Winter, and the following Summer they will produce Flowers. Theſe Plants are perennial, ſo that if they ſhould not perfect their Seeds, the Plants may be maintained for ſeveral Years.

ORYZA ; [ὀρυζα, of ὀρυσσω, to *dig,* becauſe the Earth muſt be dug before the Seeds are ſown]. Rice.

The *Characters* are ;

It hath its Grains diſpos'd into a Panicle, which are almoſt of an oval Figure, and are cover'd with a thick Huſk, ſomewhat like Barley.

There is but one *Species* of this Plant ; *viz.*

Oryza. *Matth.* Rice.

This Grain is greatly cultivated in moſt of the Eaſtern Countries, where it is the chief Support of the Inhabitants ; and great Quantities of it are brought into *England* and other *European* Countries every Year, where it is in great Eſteem for Puddings, *&c.* it being too tender to be produc'd in theſe Northern Countries, without the Aſſiſtance of artificial Heat : But from ſome Seeds which were formerly ſent to *South-Carolina,* there have been great Quantities produc'd, and it is found to ſucceed equally as well there as in its native Country, which is a very great Improvement to our *American* Settlements.

This Plant grows upon moiſt Soils, where the Ground can be flow'd over with Water after it is come up; ſo that whoever would cultivate it in *England* for Curioſity, ſhould ſow the Seeds upon a Hot-bed: And when the Plants are come up, they ſhould be tranſplanted into Pots fill'd with rich light Earth, and placed in Pans of Water, which ſhould be plunged into a Hot-bed, and as the Water waſtes, ſo it muſt, from Time to Time, be renew'd again: In *July* theſe Plants may be ſet abroad in a warm Situation, ſtill preſerving the Water in the Pans, otherwiſe they will not thrive; and towards the latter End of *Auguſt* they will produce their Grain, which will ripen tolerably well, provided the Autumn proves favourable.

OSIER. *Vide* Salix.

OSMUNDA, The Oſmund Royal, or flowering Fern.

This is one of the Kinds of Fern which is diſtinguiſhed from the other Sorts, by its producing Flowers on the Top of the Leaves, whereas the others for the moſt part produce them on the Back of their Leaves.

There is but one Kind of this Plant, which grows wild in *England*; but there are ſeveral Sorts of them which grow in *America*; but as they are ſeldom kept in Gardens, ſo I ſhall not enumerate their Species.

The common Sort grows on Bogs in ſeveral Parts of *England*; ſo whoever hath an Inclination to tranſplant it into Gardens, ſhould place it in a moiſt ſhady Situation, otherwiſe it will not thrive.

OX-EYE. *Vide* Buphthalmum.

OXYACANTHA. *Vide* Berberris.

OXYS; Wood-ſorrel.

The *Characters* are;

It hath a bell-ſhaped Flower, conſiſting of one Leaf, having its Brim wide expanded, and cut into ſeveral Diviſions: The Pointal, which riſes from the Flower-cup, becomes an oblong, membraneous Fruit, divided into five ſeminal Cells, opening outward from the Baſe to the Top, and incloſing Seeds which ſtart from their Lodges, by reaſon of the elaſtic Force of the Membrane which involves them.

The *Species* are;

1. Oxys *flore albo. Tourn.* Common Wood-ſorrel, with a white Flower.
2. Oxys *flore purpuraſcente. Tourn.* Wood-ſorrel, with a purpliſh Flower.
3. Oxys *lutea. J. B.* Wood-ſorrel, with a yellow Flower.
4. Oxus *lutea Americana erectior. Tourn.* Upright yellow Wood-ſorrel of *America*.
5. Oxys *bulboſa Africana rotundifolia, caulibus & floribus purpureis amplis. Hort. Amſt.* Round-leav'd *African* Wood-ſorrel, with large purple Flowers.
6. Oxys *bulboſa Æthiopica minor, folio cordato, flore ex albido purpuraſcente. Hort. Amſt.*
7. Oxys *Americana, flore rubro, fibroſa radice. Inſt. R. H.* *American* Wood-ſorrel, with a red Flower, and a fibroſe Root.
8. Oxys *lutea fruteſcens Americana, trifolii bituminoſi facie. Plum. Cat.* Yellow ſhrubby *American* Wood-ſorrel, with the Face of ſtinking Trefoil.
9. Oxys *purpurea Virginiana, radice ſquammata. Inſt. R. H.* Purple Wood-ſorrel of *Virginia*, with a ſcaly Root.
10. Oxys *bulboſa Africana rotundifolia, caulibus virentibus, floribus amplis purpureis. Breyn. Cent.* Bulbous-rooted *African* Wood-ſorrel, with round Leaves, green Stalks, and large purple Flowers.
11. Oxys *lutea annua, floribus dentatis. Feuillée. Obſ.* Yellow annual Wood-ſorrel, with indented Flowers.
12. Oxys *roſeo flore, erectior, vulgo Cullè. Feuillée. Obſ.* Upright Wood-ſorrel, with a Roſe-colour'd Flower, vulgarly call'd Cullé.
13. Oxys *ampliſſimo flore luteo. Feuillée. Obſ.* Wood-ſorrel with the largeſt yellow Flower.
14. Oxys *luteo flore, radice craſſiſſimâ. Feuillée. Obſ.* Wood-ſorrel with yellow Flowers, and a very thick Root.

The firſt Sort grows wild in Woods, and other ſhady Places, in divers Parts of *England*, and flowers in *April* and *May*. This is the Sort which is directed by the College of Phyſicians of *London* to be uſed in Medicine; but the Markets are generally ſupplied with the fourth Sort, which is not near ſo good, having very little Taſte: But the People who cultivate medicinal Plants for the Market, have propagated this Plant in their Gardens, becauſe it grows tall, and branches out greatly; ſo that they can readily gather and tie it up in Bunches for Sale: Whereas the true Sort grows cloſe to the Ground, and each Leaf riſes with a Foot-ſtalk from the Root, which renders it troubleſome to gather in Quantities; but thoſe who uſe it in Medicine ſhould be careful to have the true Sort; the Time for which is always in the Spring, whereas the other Kind is never brought to Market till the Middle of the Summer.

The ſecond Sort is a Variety of the firſt, differing only in the Colour of the Flower. This is found wild in the North of *England*, and is preſerved as a Variety by thoſe Perſons who are curious in Botany; but there is no Difference in the Taſte of this from the common Sort. Theſe two Sorts are abiding Plants, and multiply greatly by their creeping Roots, as alſo by Seeds. They ſhould be planted in a moiſt ſhady Border, either early in the Spring or at *Michaelmas*, that they may be rooted before the Froſt comes on. When the Plants are once eſtabliſhed in the Border, they will ſcatter their Seeds, and increaſe greatly. This common Wood-ſorrel is a much more grateful Acid in Sallads, than the common Sorrel; for which Purpoſe a Border of it ſhould not be wanting in the Kitchen-garden.

The third Sort is an abiding Plant, and increaſes greatly by its trailing Branches, which put out Roots at every Joint; as alſo by its Seeds, which are caſt abroad when ripe by the Elaſticity of the Veſſels in which they are contained, which renders it difficult to ſave the Seeds; for when they are ripe, on the firſt Touch, the Pods burſt, and throw out the Seeds. This is tender, and muſt be ſheltered under a Frame in Winter; otherwiſe it will not abide the Froſts, when they are very ſevere.

The fourth Sort is an annual Plant. This was originally brought from *North-America*; but where-ever it is introduced, and permitted to ſcatter its Seeds, it will maintain itſelf without any further Care, it being a very hardy Plant; and is now become more common than our own Sort in the *London* Markets.

The fifth and ſixth Sorts are preſerved in ſome curious Gardens for Variety. The fifth Sort produces large purple Flowers, which make a very pretty Appearance, and continue in Beauty a long Time, which renders it worthy of a Place in every Collection of Plants. The ſixth Sort hath not much Beauty in its Flowers, but is planted in curious Gardens for Variety. Theſe two Sorts have bulbous Roots, which increaſe pretty faſt, (eſpecially the ſixth) by which they are eaſily propagated. Theſe muſt be planted in Pots filled with freſh light Earth; and in Winter they ſhould be placed under a common Hot-bed Frame, where they ſhould have as much free Air as poſſible in mild Weather; but they muſt be ſheltered from Froſt, otherwiſe they will not live in this Country. In Summer they muſt be expoſed in a ſhady Situation, and in dry Weather muſt be often refreſhed with Water.

The ſeventh, ninth, and tenth Sorts may be treated in the ſame Manner as the former; theſe are preſerved in curious Gardens for the ſake of Variety.

The eighth Sort was diſcovered by Father *Plumier* in ſome of the *French* Settlements in *America*; it was alſo found by the late Dr. *Houſtoun* near *La Vera Cruz*, where it was growing in great Plenty. This Sort riſes to the Height of two Feet or more, and becomes a little Shrub, but it hath little Acidity in the Leaves. This is tenderer than either of the former Sorts, ſo ſhould be kept warmer in Winter, otherwiſe it will not live in this Country.

The eleventh Sort is an annual Plant, which is cultivated in all the Gardens of *Lima* and *Peru* in the *Spaniſh Weſt-Indies*, for its grateful acid Taſte, it being much uſed by the Inhabitants of thoſe Places in all their Sauces. This Sort grows larger than the common upright *American* Kind; the Flowers are yellow edged with purple.

The twelfth Sort grows plentifully in *Chili* in the *Spani* *Weſt-Indies*. It hath beautiful roſe-coloured Flowers, an grows about the ſame Height as the common upright *America* Sort.

The thirteenth Sort ſeldom riſes above two Inches high, an doth not branch as do the former Kinds; this hath very larg yellow Flowers: It grows plentifully on the Borders of th River of *Plate*.

The fourteenth Sort hath very large thick Roots, out o which come up the Leaves, which are of a bright green Colou on their upper Side, and of a Violet-Colour underneath. Th grows on all the Mountains of *Peru*.

All theſe Sorts, being Natives of warm Countries, are ſomewhat tenderer than thoſe before-mentioned, ſo muſt be place in a warm Green-houſe in Winter; but in Summer they ma be expoſed to the open Air, and muſt be plentifully watered i dry Weather. Theſe Plants will all of them produce Seeds i this Country, by which they may be propagated.

P A

PADUS, *vide* Ceraſus.

PÆONIA; [ſo call'd of *Pæon* the Phyſician, becauſe he is ſaid to have cured *Pluto*, being wounded by *Hercules*, with this Herb] The Peony.

The *Characters* are;

It hath a Flower compos'd of ſeveral Leaves, which are plac'd orbicularly, and expand in Form of a Roſe; *out of whoſe Empalement riſes the Pointal, which afterwards becomes a Fruit, in which ſeveral little Horns, bent downwards, are gather'd, as it were, into a little Head, cover'd with Down, opening lengthwiſe, containing many globular Seeds.*

1. Pæonia *folio nigricante ſplendido, quæ mas.* C. B. P. The Male *Peony.*
2. Pæonia *mas major, flore incarnato.* *Hort. Eyſt.* The greater Male *Peony*, with a Fleſh-colour'd Flower.
3. Pæonia *communis vel fæmina.* C. B. P. The female *Peony.*
4. Pæonia *fæmina, flore pleno rubro majore.* C. B. P. Female *Peony*, with a large, double, red Flower.
5. Pæonia *pleno flore rubro, minor.* J. B. *Peony*, with a leſſer, double, red Flower.
6. Pæonia *flore exalbido pleno, major.* C. B. P. Greater *Peony*, with a double, whitiſh Flower.
7. Pæonia *Luſitanica, flore ſimplici odorato.* Portugal *Peony*, with a ſingle ſweet-ſcented Flower.
8. Pæonia *mas, foliorum ſegmentis amplioribus.* C. B. P. Male Piony, with Leaves having broader Segments.
9. Pæonia *tenuius laciniata, ſubtus pubeſcens, flore purpureo.* C. B. P. Piony with narrow jagged Leaves, which are downy underneath, and a purple Flower.
10. Pæonia *aquilinæ foliis.* C. B. P. Piony with a columbine Leaf.
11. Pæonia *flore variegato.* C. B. P.
12. Pæonia *folio ſubtus incano, flore albo vel pallido.* C. B. P. Piony with Leaves hoary underneath, and white or pale Flowers.

The firſt of theſe Sorts is chiefly propagated for the Roots, which are us'd in Medicine; for the Flowers being ſingle, do not afford near ſo much Pleaſure as thoſe with double Flowers, nor will they abide near ſo long in Beauty.

The ſecond Sorts hath larger ſingle Flowers than the firſt, but they are of a paler Colour: This is preſerv'd by Perſons who are curious in collecting the various Kinds of Flowers, but is not ſo much eſteem'd as thoſe which follow.

All the Sorts with double Flowers are preſerv'd in curious Gardens for the Beauty of their Flowers; which, when intermix'd with other large growing Plants in the Borders of large Gardens, do add to the Variety, and the Flowers are very ornamental in Baſons or Flower-pots, when plac'd in Rooms.

They are all extreamly hardy, and will grow in almoſt any Soil or Situation, which renders them more valuable, for they will thrive under the Shade of Trees; and in ſuch Places they will continue much longer in Beauty.

They are propagated by parting their Roots, which multiply very faſt. The beſt Seaſon for tranſplanting them, is towards the Latter end of *Auguſt*, or the Beginning of *September*; for if they are remov'd after their Roots have ſhot out new Fibres, they ſeldom flower ſtrong the ſucceeding Summer.

In parting of theſe Roots, you ſhould always obſerve to preſerve a Bud upon the Crown of each Off-ſet, otherwiſe they will come to nothing; nor ſhould you divide the Roots too ſmall, (eſpecially if you have regard to their blowing the following Year;) for when their Off-ſets are weak, they many times don't flower the ſucceeding Summer, or at leaſt produce but one Flower upon each Root: But where you would multiply them in Quantities, you may divide them as ſmall as you pleaſe, provided there be a Bud to each Off-ſet; but then they ſhould be planted in a Nurſery-bed, for a Seaſon or two, to get Strength, before they are plac'd in the Flower Garden.

The ſingle Sorts may be propagated from Seeds (which they generally produce in large Quantities, where the Flowers are permitted to remain;) which ſhould be ſown in the Middle of *Auguſt* upon a Bed of light freſh Earth, covering them over about half an Inch thick with the ſame light Earth: The Spring following the Plants will come up; when they ſhould be carefully clear'd from Weeds, and in very dry Weather refreſh'd with Water, which will greatly forward their Growth. In this Bed they ſhould remain two Years before they are tranſplanted, obſerving in *Autumn*, when the Leaves are decay'd, to ſpread ſome freſh rich Earth over the Beds about an Inch thick, and conſtantly to keep them clear from Weeds.

When you tranſplant them, (which ſhould be done in *September*) you muſt prepare ſome Beds of freſh light Earth, which ſhould be dug and well cleans'd from the Roots of all noxious Weeds; then plant the Roots therein ſix Inches aſunder, and about three Inches deep. In theſe Beds they may remain untill they flower; after which they may be tranſplanted where you deſign they ſhould grow. It is very probable there may be ſome Varieties obtained from the Seeds of theſe Plants, as is common in moſt other Flowers; ſo that thoſe which produce beautiful Flowers may be plac'd in the Flower-garden, but ſuch as continue ſingle or ill-colour'd, may be planted in Beds to propagate for medicinal Uſe.

The *Portugal Peony* may alſo be propagated either by Seeds or parting of the Roots in the ſame Manner as the other Sorts, but ſhould have a lighter Soil, and a warmer Situation. The Flowers of this kind are ſingle, but do ſmell very ſweet, which renders it worthy of a Place in every good Garden.

PALIURUS: Chriſt's Thorn.

The *Characters* are;

It hath long ſharp Sines; the Flower conſiſts of five Leaves, which expand in Form of a Roſe; *out of the Flower-cup (which is divided into ſeveral Segments) riſes the Pointal, which becomes a Fruit ſhap'd like a Bonnet, having a Shell almoſt globular, which is divided into three Cells, in each of which is contain'd one roundiſh Seed.*

We have but one *Species* of this Plant; *viz.*

Paliurus. *Dod.* Chriſt's Thorn.

This is by many Perſons ſuppos'd to be the Plant from which the Crown of Thorns which was put upon the Head of our Saviour, was compos'd: The Truth of which is ſupported by many Travellers of Credit, who affirm, That this is one of the moſt common Shrubs in the Country of *Judea*; and from the Pliableneſs of its Branches, which may be eaſily wrought into any Figure, it may afford a Probability.

It may be propagated by laying down its tender Branches in the Spring of the Year; which if carefully ſupply'd with Water in dry Weather, will take Root in a Year's time, and may then be taken off from the old Plant, and tranſplanted where it is to remain.

The beſt Time for tranſplanting this Plant is in the Beginning of *April*, juſt before it begins to ſhoot, obſerving to lay ſome Mulch upon the Ground about their Roots to prevent 'em from drying, as alſo to refreſh them now and then with a little Water until they have taken freſh Root, after which they will require but very little Care. They are very hardy, and will grow to be ten or twelve Feet high, if planted in a dry Soil, and a warm Situation. There is little Beauty in this Plant, but it is kept in Gardens as a Curioſity.

PALMA; The Palm-Tree.

The *Characters* are;

It hath a ſingle unbranch'd Stalk; the Leaves are diſpos'd in a circular Form on the Top, which when they wither, or fall off with Age, new ones always ariſe out of the Middle of the remaining ones; among which, certain Sheaths or plain Twigs break forth, opening from the Bottom to the Top, very full of Flowers and Cluſters of Embryo's.

The *Species* are;

1. Palma *major.* C. B. P. The greater *Palm* or *Date-tree.*
2. Palma *minor.* C. B. P. The Dwarf *Palm*, with prickly Footſtalks.
3. Palma *Braſilienſis prunifera, folio plicatili ſeu flabelliformi, caudice ſquamato. Raii Hiſt.* The Palmetto-tree.
4. Palma *altiſſima non ſpinoſa, fructu pruniformi minore racemoſo ſparſo. Sloan. Cat.* The Cabbage-tree.
5. Palma *foliorum pediculis ſpinoſis, fructu pruniformi luteo oleoſo. Sloan. Cat.* The oily *Palm-tree.*
6. Palma *tota ſpinoſa major, fructu pruniformi. Sloan. Cat.* The great Macaw-tree.

7. PALMA *humilis dactylifera radice repentiſſima ſobolifera, folio flabelliformi, pedunculo vix ſpinoſo. Boerh. Ind.* The Dwarf *Palm*, with ſcarcely any Prickles upon the Footſtalks.

8. PALMA *foliis longiſſimis pendulis, abſque ullo pedunculo ex caudice glabro enatis. Boerh. Ind.* The Dragon-tree.

9. PALMA *Japonica, ſpinoſis pediculis, polypodii folio. Par. Bat.* The *Palm-tree* from *Japan*, with prickly Footſtalks, and a Leaf like *Polypody*.

Theſe are all the Sorts of Palms I have obſerv'd now growing in the *Engliſh* Gardens.

Theſe Plants may be eaſily produc'd from the Seeds (provided they are freſh); which ſhould be ſown in Pots fill'd with light rich Earth, and plung'd into a Hot-bed of Tanners Bark; which ſhould be kept in a moderate Temper, and the Earth frequently refreſh'd with Water.

When the Plants are come up, they ſhould be each planted into a ſeparate ſmall Pot fill'd with the ſame light rich Earth, and plung'd into a Hot-bed again, obſerving to refreſh 'em with Water, as alſo to let them have Air in Proportion to the Warmth of the Seaſon, and the Bed in which they are plac'd: During the Summer-time they ſhould remain in the ſame Hot-bed, but in *Auguſt* you ſhould let them have a great Share of Air to harden them againſt the Approach of Winter; for if they are too much forc'd, they will be ſo tender as not to be preſerv'd through the Winter without much Difficulty, eſpecially if you have not the Conveniency of a Bark-Stove to keep them in.

The Beginning of *October*, you muſt remove the Plants into the Stove, placing them where they may have a great Share of Heat (theſe being ſomewhat tenderer, while young, than after they have acquir'd ſome Strength); tho' indeed, they may be ſometimes preſerv'd alive in a cooler Situation, yet their Progreſs would be ſo much retarded, as not to recover their Vigour the ſucceeding Summer: Nor is it worth the Trouble of raiſing theſe Plants from Seeds, where a Perſon has not the Conveniency of a good Stove to forward their Growth; for where this is wanting, they will not grow to any tolerable Size in eight or ten years.

Whenever theſe Plants are remov'd, (which ſhould be done once a Year) you muſt be very careful not to cut or injure their large Roots, which is very hurtful to them, but you ſhould clear off all the ſmall Fibres which are inclinable to Mouldineſs; for if theſe are left on, they will, in time, decay, and hinder the freſh Fibres from coming out, which will greatly retard the Growth of the Plants.

The Soil in which theſe Plants ſhould be plac'd, muſt be compos'd in the following manner; viz. A third Part of light freſh Earth taken from a Paſture-ground, a third part Sea-ſand, and the other part rotten Dung, or Tanners Bark: Theſe ſhould be carefully mix'd, and laid in a Heap three or four Months at leaſt before it is us'd, but ſhould be often turn'd over, to prevent the Growth of Weeds, and to ſweeten the Earth.

You ſhould alſo obſerve to allow them Pots proportionable to the Sizes of the Plants, but you muſt never let them be too large, which is of worſe Conſequence than if they are too ſmall. During the Summer-ſeaſon, they ſhould be frequently refreſh'd with Water, but you muſt be careful not to give it in too great Quantities; and in Winter they muſt be now and then refreſh'd, eſpecially if they are plac'd in a warm Stove, otherwiſe they will require very little Water at that Seaſon.

Theſe Plants are moſt of them very ſlow Growers even in their Native Countries, notwithſtanding they do arrive to a great Magnitude; for it has been often obſerv'd by ſeveral of the old Inhabitants of thoſe Countries, that the Plants of ſome of theſe Kinds, have not advanc'd two Feet in Height in twenty Years; ſo that when they are brought into theſe Countries, it can't be expected they ſhould advance very faſt, eſpecially where there is not due Care taken to preſerve them warm in Winter: But however ſlow of Growth theſe Plants are in their Native Countries, yet they may be with us greatly forwarded by placing the Pots in a Hot-bed of Tanners Bark; which ſhould be renew'd as often as is neceſſary, and the Plants always preſerv'd therein both Winter and Summer, obſerving to ſhift them into larger Pots as they advance in Growth, as alſo to ſupply them with Water: In which Management I have had ſeveral of them come on very faſt; for I obſerve the Roots of theſe Plants are very apt to root into the Bark (if their Pots remain a conſiderable Time without ſhifting) where they meet with a gentle Warmth, and the Moiſture ariſing from the Fermentation of the Bark, doth preſerve their Fibres plump and vigorous.

The *Date Palm* is of very ſlow Growth with us, but is eaſily produc'd from Seeds, taken out of the Fruit, which are brought into *England* in great Plenty; but there are very few of theſe Plants of any conſiderable Size at preſent in the *Engliſh* Gardens.

The *Dwarf Palm*, with prickly Footſtalks, as alſo that with few Prickles, are of humble Growth in their Native Countries, ſeldom riſing above four or five Feet high, but do extend their Roots very far, and increaſe thereby in the ſame ſame Manner as the common Fern doth, ſo that the waſte Ground which is not cultivated, is over-run with the Plants; the Leaves of which the Inhabitants cut, and ſend into theſe Countries to make Flag-Brooms. Theſe grow in *Spain*, *Portugal* and *Italy*, and are much hardier than any of the other Sorts.

The *Palmetto-Tree* is brought from the *Weſt-Indies*, where it grows to be a very large Tree; the Leaves of which the Inhabitants thatch their Houſes withal, for which Purpoſe they are very uſeful in thoſe Countries: Theſe Leaves, before they are expanded, are cut, and brought into *England* to make Womens plaited Hats, which were, a few Years ſince, greatly in Faſhion; and the Berries of theſe Trees were formerly much in Uſe in *England* for Buttons. Theſe were ſome of the chief Commodities which the *Bermuda Iſlands* did afford for Manufactory, but, at preſent, they are both diſus'd in *England*.

The *Cabbage-Tree* is very common in the *Caribbee Iſlands*, where it grows to a prodigious Height; *Ligon*, in his *Hiſtory of Barbados*, ſays, There are ſome of theſe Trees above two hundred Feet high, and that it is commonly a hundred Years before they arrive at Maturity enough to produce Fruit: The Leaves of this Tree envelope each other, ſo that thoſe which are inclos'd, being depriv'd of the Air, are blanch'd, which is the Part the Inhabitants cut for Plait for Hats, *&c.* and the *Gemma* or young Shoots are pickled, and ſent into *England* by the Name of *Cabbage*: But whenever this Part is cut out, the Trees are deſtroy'd, nor do they riſe again from the old Roots, ſo that there are very few Trees left remaining near Plantations, except for Ornament; for their Stems being exceeding ſtrait, and their Leaves being produc'd very regularly at Top, do afford a moſt beautiful Proſpect; for which Reaſon the Planters generally ſpare two or three of them near their Habitations.

The *Oily Palm* grows in great Plenty on the Coaſt of *Guiney*, as alſo on *Cape Verd* Iſland, where they grow as high as the Main-Maſt of a Ship: But theſe Trees have been tranſplanted to *Jamaica* and *Barbadoes*, in both which Places they thrive very well. The Inhabitants make an Oil from the Pulp of the Fruit, and draw a Wine from the Body of the Trees, which inebriates; and with the Rind of theſe Trees they make Mats to lie upon. This Sort will eaſily riſe from Seeds, and if kept warm, will grow much faſter than the *Date Palm*.

The *Macaw-Tree* is very common in the *Caribbee Iſlands*, where the *Negroes* pierce the tender Fruit, from whence flows out a pleaſant Liquor, which they are very fond of; and the Body of the Tree affords a ſolid Timber, with which they make *Javelins*, *Arrows*, &c. and is by ſome ſuppos'd to be a Sort of *Ebony*. This Tree grows very ſlow, and requires to be kept very warm in Winter.

The *Dragon Tree* is very common in the *Madera's* and the *Canary Iſlands*, where they grow to be large Trees; from the Bodies of which it is ſuppos'd the Dragon's Blood doth flow. This Plant ariſes very eaſily from the Seeds, and when it has acquir'd ſome Strength, is pretty hard.

The *Japan Palm Tree* is, at preſent, very rare in *England*, being only in two or three curious Gardens: It will come up from Seeds, if they are freſh, but the Plants muſt be kept very warm, eſpecially while young, otherwiſe they will not live through our Winters.

All ſorts of *Palms* are worthy of being preſerv'd by thoſe who are curious in maintaining *Exotick* Plants, for the ſingular Structure of their Parts and Beauty of their Leaves, which make an agreeable Variety amongſt other curious Plants.

To this *Article* muſt be added;

1. PALMA *cujus fructus ſeſſilis Fauſel dicitur. C. B. P* The Palm-tree whoſe Fruit is called Fauſel.

2. PALMA *altiſſima non ſpinoſa, fructu oblongo. Houſt* The talleſt ſmooth Palm-tree, with oblong Fruit, calle Mountain *Cabbage*.

3. PALMA *coccifera, complicato folio, fructu minore. H. L* The nut-bearing Palm, with a folded Leaf, and ſmalle Fruit.

4. PALMA *Malabarica, floſculis ſtellatis, fructu long ſquammato. Plum.* Palm-tree of *Malabar*, with ſmall ſtarr Flowers, and a long ſcaly Fruit.

5. PALM

5. Palma *dactylifera, fructu acerrimo. Plum.* Date-bearing Palm-tree, with a ſharp Fruit.

6. Palma *montana Malabarica, folio magno complicato acuto, flore albo racemoſo, fructu rotundo. Plum.* Mountain Palm-tree of *Malabar*, with a large ſharp folded Leaf, white Flowers growing in Bunches, and a round Fruit.

7. Palma *prunifera Japonenſis. H. L. B.* Plum-bearing Palm of *Japon*.

8. Palma *dactyliſera & vinifera. Plum.* Date and Wine-bearing Palm-tree.

9. Palma *dactyliſera aculeata minima. Plum.* The leaſt prickly Date-bearing Palm-tree.

10. Palma *coccifera, coſtarum lateribus aculeatis. Plum.* Nut-bearing Palm-tree, with Spines growing on the Stalks.

11. Palma *dactyliſera latifolia. Plum.* Broad-leaved Date-bearing Palm-tree.

12. Palma *Indica coccifera anguloſa. C. B. P.* The Cocoa Nut *vulgò*.

The firſt Sort here mentioned is a Native of the *Eaſt-Indies*: The Fruit of this Kind is directed by the College of Phyſicians to be uſed in Medicine, but it is rarely brought to *England*. The ſecond Sort was diſcovered by the late Dr. *Houſtoun*, growing on the Hills near *La Vera Cruz*; the Fruit of this Kind is about an Inch and half in Length, and near two Inches in Circumference. The Flower-buds, which are produced in the Centre of the Plants, are by the Natives cut, and boiled to eat with their Meat, and are by them called the Mountain *Cabbage*.

The third Sort grows plentifully in ſeveral Parts of the *Spaniſh Weſt-Indies*, from whence I have received the Fruit. Theſe Fruit are ſhaped exactly like the Cocoa-nut, and are incloſed in a Shell in the ſame Manner as that; but theſe are not ſo large as a Man's Fiſt, whereas the Cocoa-nuts are larger than a Man's Head.

The fifth, ſixth, eighth, ninth, tenth and eleventh Sorts, grow in ſeveral Places in the *Eaſt* and *Weſt-Indies*; for by ſeveral Writers they are mentioned to grow in the *Eaſt*, and I have received Fruit of all theſe Sorts from the *Weſt Indies*.

The ſeventh Sort is a Native of the *Eaſt-Indies*, from whence the Fruit have been brought to *England*; but I have not heard that this Kind grows in any Part of *America*. This is one of the moſt beautiful Plants, of all the Kind of *Palms*, and deſerves a Place in every good Stove. It is alſo of quicker Growth than moſt of the other Sorts; for I have known a Plant of this Kind, riſe to have a fine Stem, in eight or nine Years from the ſowing; whereas ſome of the other Kinds will not form a Stem in twenty Years.

Theſe Sorts may be all propagated by their Fruit, which ſhould be put into Pots early in the Spring of the Year, and plunged into a Hot-bed of Tanners-bark; and when the Plants are come up, they ſhould be treated in the ſame Manner as is directed in the former Part of this Article; but muſt take Notice, that ſome of theſe Sorts, whoſe Fruit have hard Shells, will remain in the Ground a whole Year before the Plants will come up, ſo that the Fruit ſhould not be thrown out of the Pots, unleſs they are rotten.

The Cocoa-nut is cultivated in moſt of the inhabited Parts of the *Eaſt* and *Weſt-Indies*, but is ſuppoſed a Native of the *Maldives*, and the deſart Iſlands of the *Eaſt-Indies*: From whence it is ſuppoſed it hath been tranſported to all the warm Parts of *America*: for it is not found in any of the inland Parts, nor any where far diſtant from Settlements. It is one of the moſt uſeful Trees to the Inhabitants of *America*, who have many of their common Neceſſaries of Life from it. The Bark of the Nut is made into Cordage, the Shell of the Nut into Drinking-bowls; the Kernel of the Nut affords them a wholſome Food, and the Milk contained in the Shell a cooling Liquor. The Leaves of the Trees are uſed for thatching their Houſes, and are alſo wrought into Baſkets, and moſt other Things which are made of Oſiers in *Europe*.

This Tree is propagated by planting of the Nuts, which in ſix Weeks or two Months after planting will come up, provided they are freſh, and thoroughly ripe, which is what few of them are, which are brought to *England*; for they always gather them before they are ripe, that they may keep during their Paſſage. So that the beſt way to bring the Nuts to *England* for planting, would be to take ſuch of them as are fully ripe, and put them up in dry Sand in a Tub, where the Vermin may not come to them; and theſe will often ſprout in their Paſſage, which will be an Advantage, becauſe then they may be immediately planted in Pots of Earth, and plunged into the Bark-bed.

Theſe Plants, in the hot Iſlands of *America*, make conſiderable Progreſs in their Growth; in which Places there are ſome Trees of very great Magnitude; but in *Europe*, this Plant is of much ſlower Growth, being many Years before it advances to any conſiderable Height; but as the young Leaves of theſe Plants are pretty large, ſo they make a good Appearance amongſt other tender exotic Plants, in one or two Years time. This Plant is preſerved in ſome curious Gardens in *England*, for Variety, where it muſt be placed in the Bark-ſtove, and managed as hath been directed for for the other Kinds of Palms; obſerving, as often as they are tranſplanted, not to cut their ſtrong Roots, which is generally Death to moſt of the Palm-kind. Theſe Plants muſt not be too much confined in their Roots; for if they are, they will make but little Progreſs: Therefore, when the young Plants have filled the Pots with their Roots, they ſhould be ſhifted into Tubs of a moderate Size, that their Roots may have room to extend: but theſe Tubs muſt be kept conſtantly plunged into the Bark-bed, otherwiſe the Plants will not thrive. The Method of raiſing theſe Plants from the Nuts, when they are planted before they have ſprouted, is fully deſcribed under the Article of raiſing exotic Seeds, in the former Part of this Work, to which the Reader is deſired to turn, to avoid Repetition.

All the Sorts of Palm-trees are Male and Female in different Trees, and it hath been always ſuppoſed neceſſary, that the two ſhould grow near each other, that the Male-tree might impregnate the Female, in order to render the Female fruitful: and where it has ſo happened that a Female Tree grew ſingly, it has been aſſerted that the Inhabitants have carried Branches of the Male-flowers, taken from Trees which grew at a Diſtance, and have faſtened them to the Female Trees, without which they have inſiſted, that the Female Trees would not produce any Fruit. But this is refuted by Father *Labat*, who affirms, that he knew a ſingle Tree of the Date-bearing Palm, which grew by the Side of an antient Convent in *Martinico*, which produced a large Quantity of fair Fruit annually; tho' there was not any other Palm-tree which grew within two Leagues of this: But he alſo affirms, that the Stones of theſe Dates would not grow; for they had planted many of them for ſeveral Years ſucceſſively, without ever raiſing a ſingle Plant; and were afterwards obliged to procure ſome Dates from *Barbary*, in order to propagate them. So that he conjectures, that all the Female Trees may produce Fruit, which may appear very fair to the Eye; but upon Examination they will be found to want the Gem or Bud, which is the Embryo of the future Plant.

This may account for the Fruit of the different Sorts of Palms not growing when they are brought to *England*; for if they are gathered from a Tree growing ſingly, having no Male Tree near it to impregnate the Ovary, it may be the true Cauſe why they do not ſucceed. Therefore thoſe Perſons who collect theſe Fruit to propagate them, ſhould always obſerve to take them from ſuch Trees as grow in the Neighbourhood of the Male.

PANCRATIUM, Sea-daffodil.

The *Characters* are;

It hath a tubulous lily-ſhaped Flower, conſiſting of one Leaf, which is deeply cut into ſix Parts; in the Middle is a Cup, which is bell-ſhaped and ſix-cornered, having a Chive proceeding from each Corner, and is joined thereto as a Part of the Cup, being of the ſame Colour at Bottom; but the Part immediately under the Apex is green: In the Centre riſes the Pointal, which extends beyond the Chives. The Empalement afterwards becomes a roundiſh Fruit, which is triangular, and divided into three Parts containing many flat or roundiſh Seeds.

The *Species* are;

1. Pancratium *Monſpeſulanum, multis Scilla alba parva. J. B.* Sea-daffadil of *Montpelier*, by many called the leſſer white Squill.

2. Pancratium *floribus rubris. Lob. Pan.* Sea-daffodil with red Flowers.

3. Pancratium *Illyricum, floribus albis.* Sea-daffodil of *Illyricum*, commonly called the third *Narciſſus* of *Matthiolus*.

4. Pancratium *Americanum, floribus niveis, odore balſami Peruviani. American* Sea-daffodil, with ſnowy Flowers, ſmelling like the Balſam of *Peru*.

5. Pancratium *Americanum, foliis latiſſimis, floribus niveis majoribus, odore balſami Peruviani. American* Sea-daffodil, with very broad Leaves, and large ſnowy Flowers, ſmelling like the Balſam of *Peru*.

6. Pancratium *alterum vernum Indicum. J. B.* Another *Indian* Sea-daffodil of the Spring.

7. Pancratium *Zeylanicum, flore albo odorato.* Sea-daffodil of *Ceylon*, with white ſweet-ſmelling Flowers.

The firſt Sort is very common on the Sea-coaſts of the *Mediterranean*, where it grows in the Sands. The ſecond is a Variety of the firſt, differing only in the Colour of its Flower. The third Sort grows plentifully on the Sands near *Naples*, and in *Sicily*, as alſo in ſeveral Iſlands of the *Archipelago*, but particularly in *Zant*, where all the Ditches are ſtored with it.

Theſe Plants are very hardy in reſpect to Cold, and may be propagated by Off-ſets from the Roots: for though they produce ripe Seeds in *England*, yet as the ſeedling Plants are many Years before they come to flower, ſo they are ſeldom propagated that Way. Theſe Roots ſhould be tranſplanted in *July*, after the Leaves and Flower-ſtems are decayed; they ſhould be planted in an Eaſt Border, where they will thrive very well, and continue longer in Flower than when they are more expoſed to the Sun; but in every other reſpect they may be treated as hath been directed for the better Sort of *Narciſſus*.

The other four Sorts are very tender, and will not live in *England*, unleſs they are preſerved in the warmeſt Stoves. Theſe may be procured from the Countries of their natural Growth, from whence their Bulbs may be eaſily brought, if they are taken out of the Ground when their Leaves begin to decay; and after drying them in the Shade, they ſhould be put up in Nets or Bags, and hung up, that the Vermin may not come to them.

The fourth Sort is very common in *Jamaica*, and moſt of the Iſlands of *America*: The fifth Sort was brought from the *Bahama-Iſlands*; the ſixth is very common in the *Spaniſh Weſt-Indies*: and the ſeventh is a Native of the Iſland of *Ceylon*.

All theſe Plants increaſe by Off-ſets from their Roots, and flower extremely well, if they are planted in Pots filled with light rich Earth, and plunged into the Bark-bed in the Stove, and managed as hath been directed for the tender Sorts of Lilio-Narciſſus.

PANICLE: A *Panicle* is a Stalk diffuſed into ſeveral Pedicles, or Foot-ſtalks, ſuſtaining the Flowers or Fruits, as in *Oats*, &c.

PANICUM, Panic.

The *Characters* are;

It is a Plant of the millet Kind, differing from that, by the Diſpoſition of the Flowers and Seeds, which, of this, grow in a cloſe thick Spike.

The *Species* are;

1. Panicum *Germanicum, ſive paniculâ minore flaviâ. C. B. P.* Yellow *German* Panic, with a ſmaller Spike.
2. Panicum *Germanicum, ſive paniculâ minore albâ. C. B. P.* White *German* Panic, with a ſmaller Spike.
3. Panicum *Germanicum, ſive paniculâ minore purpureâ. C. B. P.* Purple *German* Panic, with a ſmaller Spike.
4. Panicum *Italicum, ſive paniculâ majore. C. B. P. Italian* Panic, with a larger Spike.
5. Panicum *Indicum, ſpicâ obtuſâ cœruleâ. C. B. P. Indian* Panic, with a blue obtuſe Spike.
6. Panicum *Indicum, ſpicâ longiſſimâ. C. B. P. Indian* Panic, with a very long Spike.
7. Panicum *Americanum, ſpicâ obtuſâ brevi Inſt. R. H. American* Panic, with a ſhort obtuſe Spike.
8. Panicum *Americanum, ſpicâ longiore acutâ. Inſt. R. H. American* Panic, with a longer pointed Spike.
9. Panicum *Indicum altiſſimum, ſpicis ſimplicibus, mollibus, in foliorum alis longiſſimis pediculis inſidentibus. Inſt. R. H.* The talleſt *Indian* Panic, with a ſoft ſingle Spike, which is produced on a long Foot-ſtalk from the Wing of the Leaf.

The three firſt Sorts are only Varieties, which differ in the Colour of the Grain. Theſe are ſowed in ſeveral Parts of *Europe*, in the Fields, as Corn, for the Suſtenance of the Inhabitants; but it is reckoned not to afford ſo good Nouriſhment as *Millet*; however it is frequently uſed in ſome Parts of *Germany*, to make Puddings, Cakes and Bread. This is not ſo much eſteemed as the *Italian* Sort; but as it will ripen better in cold Countries than that, ſo it is generally cultivated, where a better Sort of Grain will not ſucceed.

The Seeds of theſe Sorts may be ſown in the Spring, at the ſame Time as *Barley* is ſown, and may be managed exactly in the ſame Way: but this ſhould not be ſown too thick; for theſe Seeds are very ſmall, and the Plants grow ſtronger, therefore require more Room. The *German* Sort doth not grow above three Feet high, unleſs it is ſown on very rich Land, in which Caſe it will riſe to be four Feet high; but the Leaves and Stems of this Corn are very large, ſo require to ſtand four or five Inches apart, otherwiſe they will grow up weak, and come to little. Theſe large growing Corns ſhould be ſown in Drills at about eighteen Inches apart, ſo that the Ground may be houghed between the Rows of Corn, to keep them clear from Weeds, and the ſtirring of the Ground will greatly improve the Corn. In *July* the Corn will ripen, when it may be cut down and dried, and then ſhould be houſed.

The *Italian* Panic grows much larger than the *German*, and produces much larger Spikes; ſo this ſhould be allowed more Room to grow, and otherwiſe it will come to little. This is alſo later before it ripens, ſo is not very proper for cold Countries.

The other Sorts are Natives of very warm Countries, where they are uſed by the Inhabitants to make Bread. Theſe grow very large, and require a good Summer, otherwiſe they will not ripen in this Country. The Seeds of theſe Kinds ſhould be ſown the latter End of *March*, or the Beginning of *April*, on a Bed of light rich Earth, in a warm Situation. They ſhould be ſown in Drills about three Feet aſunder, and when the Plants come up, they muſt be kept clear from Weeds, and thinned where they are too cloſe. When the Plants are grown pretty tall, they ſhould be ſupported by Stakes, otherwiſe the Winds will break them down; and when the Corn begins to ripen, the Birds muſt be kept from it, otherwiſe they will ſoon deſtroy it. Theſe Sorts are preſerved in ſome curious Gardens for the ſake of Variety, but they are not worth cultivating for Uſe in *England*.

PANSIES, *vide* Viola *Tricolor*.

PAPAVER. Poppy.

The *Characters* are;

The Flower, for the moſt Part, conſiſts of four Leaves, which are plac'd orbicularly, and expand in Form of a Roſe out of whoſe Flower-cup (which conſiſts of two Leaves) riſes the Pointal, which afterwards becomes a Fruit or Pod, which is oval or oblong, and adorn'd with a little Head; under which, in ſome Species, is open'd a Series of Holes quite round, into the Cavity of the Fruit, which is defended lengthwiſe with various Leaves or Plates, to which a great Number of very ſmall Seeds adhere.

The *Species* are;

1. Papaver *hortenſe, ſemine albo, ſativum Dioſcoridis, album Plinio. C. B. C.* Garden Poppy, with white Seeds.
2. Papaver *hortenſe, ſemine nigro, ſylveſtre Dioſcoridis, nigrum Plinio. C. B. P.* Garden Poppy, with black Seeds.
3. Papaver *flore pleno, rubrum. Hort. Eyſt.* Double Red Poppy.
4. Papaver *flore pleno, album. C. B. P.* Double White Poppy.
5. Papaver *flore pleno purpureo. C. B. P.* Double Purple Poppy.
6. Papaver *pleno flore, nigrum. C. B. P.* Black Double-flower'd Poppy.
7. Papaver *laciniatis floribus. C. B. P.* Poppy with jagged Flowers.
8. Papaver *flore pleno laciniato eleganter ſtriato. Hort. Ed.* Double jagged Poppy, with beautiful ſtrip'd Flowers.
9. Papaver *Orientale hirſutiſſimum, flore magno. T. Cor.* Very rough Oriental Poppy, with a large Flower.
10. Papaver *erraticum majus*, ῥοιὰς *Dioſcoridi Plinio, Theophraſto. C. B. P.* Red Poppy, *or* Corn Roſe.
11. Papaver *erraticum majus, foliis florum variegatis. H. R. Par.* Great Wild Poppy, whoſe Flower-leaves are variegated.
12. Papaver *erraticum, flore pleno. C. B. P.* Double Wild Poppy, *commonly called* The Dwarf Poppy.
13. Papaver *erraticum, flore pleno miniato. H. R. Par.* Wild Poppy, with a double Vermilion-colour'd Flower.
14. Papaver *erraticum, flore pleno igneo. H. R. Par.* Wild Poppy, with a double fiery Flower.
15. Papaver *erraticum, flore pleno igneo, marginibus candidis. H. L.* Wild Poppy, with a double fiery Flower, edg'd with white.
16. Papaver *erraticum, flore pleno Phœnicio, unguibus albis. H. R.* Wild Poppy, with a double purple Flower and white Bottom.

17. Papaver *erraticum minus. C. B. P.* Leſſer Wild Poppy, *or* Dwarf Poppy.

18. Papaver *luteum perenne, laciniato folio, Cambro-Britannicum. Raii Syn.* Welſh, *or* Yellow Wild Baſtard Poppy.

The firſt Sort is cultivated in Gardens for medicinal Uſe, and is by ſome ſuppos'd to be the Plant from whence the *Opium* is procured: Of this there are ſeveral Varieties, which chiefly differ in the Colour of their Flowers; but they are no more than ſeminal Variations, and therefore not worth enumerating in this Place.

The *Black Poppy* grows wild in divers Parts of *England*: The Seeds of this Kind are ſold to feed Birds, by the Name of *Maw Seed*. Of this Sort there are a vaſt Number of Varieties ſome of which produce exceeding large Double Flowers of various Colours, and beautifully ſtrip'd: but theſe are apt to vary from Seed; therefore you ſhould never ſave the Seeds of any but ſuch as are very double, and well-colour'd, from which you may always expect to have good Sorts produc'd.

The *Oriental Poppy* is an abiding Plant, which produces a large ſingle Flower in *May*, which makes a beautiful Appearance: This may be propagated from Seeds, or by parting their Roots; the beſt time to tranſplant them is at the Beginning of *March*: This muſt have a light Soil, and a warm Situation.

The *Red Poppy*, or *Corn Roſe*, is never propagated in Gardens, but is very common upon chalky dry Soils in almoſt every Part of *England*, where the Plants come up amongſt the Corn, and are very troubleſome. The Flowers of this Kind are brought into the Markets for Medicinal Uſe. There are many Varieties of this Plant with double Flowers, which are cultivated in the Flower Garden, but eſpecially the Dwarf Sort, of which there are ſome with very double Flowers, which are beautifully edged with white; theſe are by many Perſons ſown for Edgings to the large Borders of the Pleaſure-garden; tho' I think them no ways proper for this, ſince their Flowers are but of a ſhort Duration; and the Plants, when their Seeds are perfected, do immediately decay, ſo that they appear unſightly. Beſides, where they grow very cloſe, the Flowers are generally ſmall: but if they are ſown in Patches upon the Borders, and when the Plants come up, are thinned out, ſo as to leave but three or four in each Place, they will flower very well, and look very beautifully.

All the Sorts of *Poppies* ſhould be ſown in *Autumn*; (for when they are ſown in the *Spring*, the Plants have not Time enough to get Strength before the hot Weather cauſes them to run up to flower; ſo that their Flowers are never ſo large or double as thoſe ſown in the *Autumn*). When the Plants come up, they ſhould be carefully clear'd from Weeds, which is all the Culture they require, (except to pull them up where they are too thick); for they thrive better when they are ſuffer'd to remain where they were ſown, than if they were tranſplanted: but you ſhould obſerve to let them have Room in Proportion to the Growth of the Plants. This Sort firſt mention'd grows very large, and tall, therefore ſhould be not cloſer than eight or ten Inches. But the *Black* Sort, may ſtand ſomewhat nearer; tho' this appears handſomer when the Plants ſtand ſingle; therefore it is the better way to ſcatter the Seeds of thoſe which have beautiful Flowers very thin over the Borders of the Flower-garden: and when the Plants come up they may be pull'd out where they are not well ſituated, leaving here and there a Plant, as the other Flowers in the Borders will admit, where, at the Seaſon of their Flowering, they will make a pretty Variety amongſt the Flowers: but they are of ſhort Duration; and having an ill Scent, they are leſs eſteem'd of late Years, ſince the Plenty of other more valuable Flowers.

PAPAVER CORNICULATUM: *vide* Glaucium.

PAPAVER SPINOSUM: *vide* Argemone.

PAPAYA, Papaw-Tree.

The *Characters* are;

It hath a ſimple Stalk: the Flowers are Male and Female in different Plants; the Male Flowers (which are barren) are tubulous, conſiſting of one Leaf, and expand in the form of a Star: the Female Flowers conſiſt of ſeveral Leaves, which expand in form of a Roſe, *out of whoſe Flower-cup riſes the Pointal, which afterwards becomes a fleſhy Fruit, ſhaped like a* Cucumber *or* Melon, *containing many ſmall oblong furrow'd Seeds.*

The *Species* are;

1. Papaya *fructu Melopeponis effigie. Plum.* The Female Papaw-Tree, bearing a Fruit like the *Melopepo*.

2. Papaya *fructu maximo, Peponis effigie. Plum.* The Female Papaw-Tree, bearing a Fruit like the *Pumkin*.

3. Papaya *mas. Boerh. Ind.* The Male Papaw-Tree.

Theſe Plants are very common in the *Caribbee Iſlands*, where they ariſe from Seeds, and will produce Fruit in eight or ten Months after.

The Fruit is cut before it is ripe, and afterwards ſliced and ſoak'd in Water until the milky Juice be out, and then boil'd and eat as *Turneps*, or baked as *Apples*; and when ripe, it is eaten as *Melons* with Pepper and Sugar, by the Inhabitants of thoſe Countries.

The Flowers of the Male Sort, as alſo the Fruit of the Female, are preſerved, and ſent over as a Sweetmeat to *Europe*, and are ſaid to be very cooling and cordial.

In *England* theſe Plants are preſerved as Curioſities, by ſuch as delight in Exoticks: they are eaſily raiſed from the Seeds, (which are generally brought from the *Weſt Indies* in Plenty every Year) which ſhould be ſown upon a Hot-bed in *February* or *March*; and when the Plants are come up, they ſhould be planted each in a ſeparate ſmall Pot fill'd with rich light Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to water and ſhade them until they have taken Root; after which, you ſhould let them have Air in Proportion to the Warmth of the Seaſon, by raiſing the Glaſſes with Bricks, &c. and you muſt often refreſh them with Water.

When the Plants have grown ſo as to fill the Pots with their Roots, they muſt be ſhaken out of them, preſerving the Earth as intire as poſſible to their Roots, and placed in larger Pots, which ſhould be fill'd with the ſame light Earth, and plunged again into the Hot-bed, obſerving to give them Air and Water, as was before directed: and thus from time to time, as the Plants increaſe their Stature, you ſhould ſhift them into larger Pots, which will cauſe them to be very ſtrong; and if you keep them in the Hot-bed all the *Summer*, and give them due attendance, they will riſe to ſix or ſeven Feet High before *Winter*.

In *October* they ſhould be placed into a new Hot-bed in the Bark-ſtove with other tender Exotick Plants, where, during the Winter Seaſon, they muſt be carefully look'd after, to water and cleanſe them well from Vermin and Filth; and the Stove ſhould be kept nearly to the *Anana's* Heat, as mark'd on Mr. *Fowler's Thermometers*, in which they will thrive and retain their beautiful large Leaves all the *Winter*: and the Male Sort will often continue to produce freſh Flowers all that Seaſon, provided you do not keep them too dry. The ſecond Year the Female Sort will flower, and, if duly attended, will perfect the Fruit the following *Spring*.

Theſe Plants make a very beautiful Appearance (when grown large) amongſt other curious Exoticks in the Stove, and deſerve a Place in every good Collection of rare Plants.

PAPILIONACEOUS: A *Papilionaceous* (or *Pea-bloom*) *Flower*, is ſo call'd, becauſe, in ſome meaſure, it reſembles a Butterfly with its Wings expanded: it always conſiſts of theſe four Parts; the *Vexillum* or Standard, which is a large erect Segment or Petal; the *Alæ* or two Wings, which compoſe the Sides; and the *Carina* or Keel, which is a concave Petal or Segment, reſembling the lower Part of a Boat; this Keel is ſometimes intire, and ſometimes it conſiſts of two Petals or Segments adhering pretty cloſely together: Of this Tribe are *Peas*, *Beans*, *Kidney-Beans*, *Vetches*, and other Leguminous Plants.

PAPPOSE PLANTS, are ſuch as have their Seeds cover'd with a Down, which adheres to the upper Part of the Seed, and are of Uſe to ſpread them when ripe, by ſuſtaining them in the Air, ſo that they may be convey'd to a great Diſtance: Of this Kind are the *Sow-thiſtles*, *Hawkweeds*, *Dandelion*, *Starworts*, &c.

PARASITICAL PLANTS, are ſuch as are produced out of the Trunk or Branches of other Plants, from whence they receive their Nouriſhment, and will not grow upon the Ground, as the *Miſletoe*, &c.

PARIETARIA, [ſo called of *Paries*, Lat. a *Wall*, becauſe it grows on old Walls] Pellitory.

The *Characters* are;

It hath an apetalous Flower, whoſe Flower-cup is divided into four Parts, which is ſometimes Bell-ſhaped, and at other *times ſhaped like a Funnel, with four* Stamina *(or Threads) ſurrounding the Pointal; which Pointal becomes, for the moſt part, an oblong Seed, ſurrounded by the Flower-cup: to which may be added, the Flowers are produced from the Wings of the Leaves.*

The *Species* are;

1. PARIETARIA *officinarum, & Dioſcoridis. C. B. P.* Pellitory of the Wall.
2. PARIETARIA *minor, Ocymi folio. C. B. P.* Leſſer Pellitory, with a Baſil Leaf.

The firſt of theſe Plants is ſuppoſed to be the true Sort which is recommended by *Dioſcoridis* for Medicinal Uſe: this is the moſt common in *Germany*, and ſome other Countries; but it is very different from that which grows wild in *England*, which is more like the ſecond Sort, tho' I can't poſitively affirm it to be the ſame.

Theſe Plants grow wild upon old Walls and Buildings in great Plenty; but may be cultivated by ſowing their Seeds in *Autumn*, upon a dry gravelly or ſtony Soil, where they will thrive much better than in a richer Soil, and are preferable for Uſe to thoſe which grow in a moiſt rich Ground; for tho' in ſuch Places they will often be very rank, yet they are not near ſo ſtrongly ſcented.

PARKINSONIA.

The *Characters* are;

It hath a polypetalous anomalous Flower, conſiſting of five diſſimilar Leaves, from whoſe Cup ariſes the Pointal, which afterward becomes a rough jointed Point, each Knot or Joint containing one kidney-ſhaped Seed.

We know but one *Species* of this Plant, which is;

PARKINSONIA *aculeata, foliis minutis, uni coſtæ adnexis. Plum. Nov. Gen.* Prickly Parkinſonia, with very ſmall Leaves, faſtened to one Middle Rib.

This Plant was diſcovered by Father *Plumier* in *America*, who gave it this Name in Honour to the Memory of Mr. *John Parkinſon*, who publiſhed a univerſal Hiſtory of Plants in *Engliſh*, in the Year 1640.

It is very common in the *Spaniſh Weſt-Indies*, but of late Years it has been introdued into the *Engliſh* Settlements in *America*, for the Beauty and Sweetneſs of its Flowers. This in the Countries where it grows, naturally riſes to be a Tree of twenty Feet high or more, and bears long ſlender Bunches of yellow Flowers, which hang down after the ſame Manner as the *Laburnum*. Theſe Flowers have a moſt agreeable ſweet Scent, ſo as to perfume the Air to a conſiderable Diſtance round about the Trees; for which Reaſon the Inhabitants of the *Weſt-Indies* plant them near their Habitations. And tho' this Plant has not been introduced many Years into the *Engliſh* Settlements, yet it is now become ſo common in all the Iſlands, that but few Houſes are without ſome of the Trees near it; for it produces Flowers and Seeds in Plenty, in about two Years, from Seed; ſo that it may ſoon be made common in all hot Countries: but in *Europe* it requires a Stove, otherwiſe it will not live thro' the Winter.

This Plant is propagated by Seeds, which ſhould be ſown in ſmall Pots filled with light freſh Earth early in the Spring, and the Pots muſt be plunged into a Hot-bed of Tanners-bark, where, in about three Weeks or a Month's Time, the Plants will come up; when they ſhould be kept clear from Weeds, and frequently refreſhed with Water. In a little Time theſe Plants will be fit to tranſplant; which ſhould be done very carefully, ſo as not to injure their Roots. They muſt be each planted into a ſeparate halfpenny Pot filled with light freſh Earth, and then plunged into the Hot-bed again, obſerving to ſtir up the Tan; and if it hath loſt its Heat, there ſhould be ſome freſh Tan added, to renew the Heat again. Then ſhade the Plants from the Heat of the Sun, until they have taken new Root; after which Time they ſhould have freſh Air admitted to them every Day, in proportion to the Warmth of the Seaſon, by raiſing of the Glaſſes of the Hot-bed with bricks or Stones; and they muſt be conſtantly ſupplied with Water every other Day, in warm Weather. With this Management the Plants will grow ſo faſt, as to fill the Pots with their Roots by the Beginning of *July*. At which Time they ſhould be ſhifted into Pots a little larger than the former, and plunged again into the Bark-bed, provided the Plants are not too tall to remain under the Frame, without Danger of being ſcorched by the Glaſſes; in which Caſe they muſt be plunged into the Bark-bed in the Stove, where they may have Room to grow.

As theſe Plants are very tender, ſo they ſhould be conſtantly kept in the Bark-ſtove, with other tender exotic Plants of the ſame Country, obſerving in the Winter Seaſon to refreſh them two or three times a Week with Water, but it ſhould be given to them ſparingly in cold Weather. In Summer they muſt be ſupplied more plentifully with Water, and ſhould have a large Share of free Air in hot Weather. The Plants muſt alſo be ſhifted every Year, and as they grow in Magnitude, ſo they ſhould be allowed larger Pots, being careful not to over-pot them; which is very injurious to moſt Plants, but eſpecially to theſe very tender ones. If the Plants thrive, they will produce Flowers the third Year, when they will make a fine Appearance in the Stove.

PARNASSIA, Graſs of *Parnaſſus.*

The *Characters* are;

It hath a roſe-ſhaped Flower, conſiſting of five Leaves, at the bottom which are ſmall, fringed, and noted leaves, of a greeniſh Colour, and placed orbicularly; out of the Flower-cup riſes the Pointal, which afterward turns to a membranaceous Fruit, which is oval, having but one Cell, which is filled with Seeds, that for the moſt part adhere to a four-fold Placenta.

The *Species* are;

1. PARNASSIA *paluſtris & vulgaris. Inſt. R. H.* Common Marſh-graſs of *Parnaſſus.*
2. PARNASSIA *vulgaris, flore pleno.* Common Graſs of *Parnaſſus*; with a double Flower.

The former of theſe Sorts grows wild in moiſt Meadows, in ſeveral Parts of *England*, but particularly in the *North*; but it doth not grow in the Neighbourhood of *London*, any nearer than on the other Side of *Watford*, in the low Meadows by *Caſſioberry*, where it is in pretty great Plenty.

The other Sort is an accidental Variety of the former, which has been diſcovered wild, and tranſplanted into Gardens. This is but rarely to be found, being in very few Gardens at preſent.

Theſe Plants may be taken up from the natural Places of their Growth, with Balls of Earth to their Roots, and planted into Pots filled with pretty ſtrong freſh undunged Earth, and placed in a ſhady Situation, where, if they are conſtantly watered, they will thrive very well, and flower every Summer. But if the Plants are planted in the full Ground, it ſhould be in a very moiſt ſhady Border, otherwiſe they will not live; and theſe ſhould be as duly watered, as thoſe in the Pots in dry Weather, to make them produce ſtrong Flowers.

They may be propagated by parting of their Roots, which ſhould be done in *March*, before they put out new Leaves; but the Roots ſhould not be divided too ſmall, for that will prevent their Flowering the following Summer; theſe Roots ſhould always be planted in pretty ſtrong freſh Earth, for they will not thrive in a light rich Soil. In the Spring they muſt be conſtantly watered, if the Seaſon ſhould prove dry, otherwiſe they will not flower, nor ſhould they be parted oftener than every other Year, to have them ſtrong. Theſe Plants flower in *July*, and their Seeds are ripe the latter End of *Auguſt*.

It is called *Parnaſſia*, from *Mount Parnaſſus*, on which it was ſuppoſed to grow; and from the Cattle feeding on it, it was called a Graſs, tho' the Plant has no Reſemblance to any of the Graſs-kind, but is more like to the *Ranunculus* in Flower, and the Leaves are pretty broad, oblong and ſmooth.

PARONYCHIA, Mountain Knot-graſs.

The *Characters* are;

It hath an apetalous Flower, conſiſting of ſeveral Chives, which riſe from the Flower-cup, which is ſhaped like the Pelvis, and cut into five Parts for the moſt part like a Crown; the Pointal afterwards becomes a round Seed, wrapt up in a five-cornered Huſk, which was before the Flower-cup.

The *Species* are;

1. PARONYCHIA *Hiſpanica. Cluſ. Hiſp.* Spaniſh Mountain Knot-graſs.
2. PARONYCHIA *Narbonenſis erecta. Inſt. R. H.* Upright Mountain Knot-graſs of *Narbonne.*
3. PARONYCHIA *Hiſpanica ſupina Alſine folia, capitulis minus compactis. Inſt. R. H.* Low *Spaniſh* Mountain Knot-graſs,

graſs, with a thickweed Leaf, and the Heads leſs compact.

4. PARONYCHIA *Hiſpanica fruticoſa, myrti folio. Inſt. R. H.* Shrubby *Spaniſh* Mountain Knot-graſs, with a myrtle Leaf.

5. PARONYCHIA *Luſitanica, polygoni folio, capitulis echinatis. Inſt. R. H. Portugal* Mountain Knot-graſs, with prickly Heads.

6. PARONYCHIA *Orientalis humifuſa, ſerpilli folio. Tourn. Cor.* Dwarf Eaſtern Mountain Knot-graſs, with a Mother of Thyme-leaf.

The five Sorts firſt mentioned grow wild in *Spain, Portugal* and the *South* of *France*, where they generally are found near the Sea, on the Sides of Banks; but the ſixth Sort was diſcovered by Dr. *Tournefort* in the *Levant*. They are all (except the ſecond and fourth Sorts) low Plants, which trail on the Ground, in the ſame Manner as our common Knot-graſs, but continue ſeveral Years.

Theſe Plants are preſerved by thoſe who are curious in Botany, for the ſake of Variety; but are ſeldom admitted into other Gardens: tho' the firſt Sort may have Room in every good Garden, for the fine Appearance it makes in Autumn, when the ſilvery ſcaly Heads, which are produced at every Joint of the Branches, make a goodly Shew.

They may all be propagated by ſowing of their Seeds on a Bed of light freſh Earth, in an open Situation, about the Middle or latter End of *March*; and when the Plants come up, they ſhould be carefully weeded; and if the Seaſon ſhould prove dry, they muſt be now and then watered. When the Plants are large enough to tranſplant, they ſhould be carefully taken up, and ſome of them planted in Pots, and the others on a warm Border, where they may be ſheltered in Winter, otherwiſe they will not live in this Country. Thoſe which are planted in Pots, ſhould be placed under a Hot-bed Frame, where they may be ſcreened from hard Froſts, but ſhould have as much free Air as poſſible in mild Weather. With this management the Plants may be preſerved many Years, and will flower every Seaſon; but they rarely produce any Seeds in this Country.

PARSLEY: *vide* Apium.

PARSNIP: *vide* Paſtinaca.

PARTERRE, is a level Diviſion of Ground, which, for the moſt part, faces the South and beſt Front of an Houſe, and is generally furniſh'd with *Greens, Flowers*, &c.

There are ſeveral Sorts of *Parterres*, as *Bowling-green* or *Plain, Parterres* of *Embroidery*, &c.

Plain Parterres are more beautiful in *England* than in any other Countries, by reaſon of the Excellency of our Turf, and that Decency and unaffected Simplicity that it affords to the Eye of the Spectator.

Others are cut into Shell and Scroll-work, with Sand-Alleys between them, which are the fineſt *Parterre* Works eſteem'd in *England*.

As to the general Proportion of *Parterres*, an Oblong or Long Square is accounted the moſt proper Figure for a *Parterre*; becauſe by the Rules of *Perſpective*, or the natural Declenſion of the viſual Rays in *Opticks*, a long Square ſinks almoſt to a Square, and an exact Square appears much leſs than it really is; therefore a *Parterre* ſhould not be leſs than twice as long as it is broad; twice and a half is accounted a very good Proportion, and it is very rare that three times is exceeded.

As to the Breadth of a *Parterre*, it is to take its Dimenſions from the Breadth of the Front of the Houſe: if it be not above an hundred Feet, it will be too narrow; and if the Front be two hundred Feet, the *Parterre* muſt be of the ſame Breadth.

Some do not approve of making *Parterres* very broad, becauſe it makes them appear too ſhort; when nothing is more pleaſing to the Eye, than a contracted regular Conduct and View, as ſoon as a Perſon goes out of an Houſe or Building: and a forward direct View is the beſt, whether it be either *Parterre* or *Lawn*, or any other open Space, either two, three, or four-fold to the Width: and for that Reaſon, thoſe Deſigns may juſtly be diſapproved, by which the Nobleneſs of the View is marred at the immediate Entrance into the Garden, the Angle of Light being broken and confuſed.

The making of *Parterres* too large, cauſes a great Expence, and at the ſame time occaſions a Dimunition of Wood, which is conſequently the moſt valuable Part of a Garden.

There ſhould be a Terraſs Walk on each Side the *Parterre*, for an Elevation proper for View; and therefore there ſhould never be the Flat of a *Parterre* between Terraſs Walk and Terraſs Walk above three hundred Feet; nor can it be well made leſs than an hundred and forty; and then the Length, at twice and a half the Breadth, would be three hundred and fifty Feet, which ſome account a handſome proportion.

As to the adorning and furniſhing theſe *Parterres*, whether it be plain, or with Embroidery, that depends much upon the Form of them, and therefore muſt be left to the Judgment and Fancy of the Deſigner.

PARTHENIASTRUM, Baſtard Feaverfew.

The *Characters* are:

It hath a radiated diſcous Flower, conſiſting of ſeveral Florets, which occupy the Diſk, but are barren; the half Florets, which are ſhaped like a Heart, are ſucceeded by black Seeds, which are naked, having no Down adhering to them: To which may be added, The Flower-cup is ſimple, and cut into five Parts to the Bottom.

The *Species* are;

1. PARTHENIASTRUM *artemiſiæ folio, flore albo. Acad. Reg. Scien.* Baſtard Feaverfew, with a Mugwort Leaf, and a white Flower.

2. PARTHENIASTRUM *helenii folio. Hort. Elth.* Baſtard Feaverfew, with an Elecampane Leaf.

The firſt Sort grows wild in great plenty in the Iſland of *Jamaica*, and in ſome other of the *Engliſh* Settlements in the *Weſt-Indies*, where it is called Wild Wormwood, and is uſed by the Inhabitants as a vulnerary Herb.

The ſecond Sort grows plentifully in ſeveral Parts of the *Spaniſh Weſt-Indies*, from whence the Seeds have been brought to *Europe*.

Theſe are both annual Plants, which may be propagated by ſowing of their Seeds on a Hot-bed early in the *Spring*, and when the Plants are come up, they ſhould be tranſplanted on another Hot-bed, at about five or ſix Inches Diſtance; obſerving to water and ſhade them until they have taken new Root; after which Time they muſt have a pretty large Share of freſh Air in warm Weather, by raiſing of the Glaſſes of the Hot-bed every Day; and they muſt be duly watered every other Day at leaſt. When the Plants have grown ſo as to meet each other, they ſhould be carefully taken up, preſerving a Ball of Earth to their Roots, and each planted into a ſeparate Pot, filled with light rich Earth; and if they are plunged into a moderate Hot-bed, it will greatly facilitate their taking freſh Root; but where this Convenience is wanting, the Plants ſhould be removed to a warm ſheltered Situation, where they muſt be ſhaded from the Sun until they have taken new Root; after which Time they may be expoſed, with other tender annual Plants, in a warm Situation, where they will flower in *July*, and their Seeds will ripen in *Auguſt*. But if the Seaſon ſhould prove cold and wet, it will be proper to have a Plant or two in Shelter, either in the Stove or under tall Frames, in order to have good Seeds, if thoſe Plants which are expoſed ſhould fail, whereby the *Species* may be preſerved.

PASQUE FLOWER: *vide* Pulſatilla.

PASSION FLOWER: *vide* Granadilla.

PASTINACA, [of *Paſtus*, Lat. *ſed*, becauſe it is a Plant whoſe Root is edible] Parſnip.

The *Characters* are;

It is a Plant with Roſe and umbellated Flowers, conſiſting of many Petals or Leaves placed orbicularly, and reſting on the Empalement, which turns to a Fruit, compoſed of two Seeds, which are oval, large, thin, border'd, and generally caſting off their Cover: To theſe Marks muſt be added, that the Leaves are winged and large.

The *Species* are;

1. PASTINACA *ſativa, latifolia. C. B. P.* Garden Parſnip.

2. PASTINACA *ſylveſtris, latifolia. C. B. P.* Wild Parſnip.

3. PASTINACA *ſylveſtris, altiſſima. Tourn.* The talleſt Wild Parſnip, or *Hercules*'s All-heal.

The firſt Sort grows wild in divers Parts of *England*, upon the Sides of dry Banks, and is by ſome affirmed to be no ways different from the ſecond Sort, but by Cultivation. Which is a very great Miſtake; for I have ſown the Seeds of both Sorts in the ſame Bed for ſeveral Years, but could not find that either Sort alter'd in the leaſt, the firſt ſtill retaining the ſame Smoothneſs in the Leaf, and the ſame pale Colour and Largeneſs of Root; as did the ſecond its uſual Roughneſs, dark green Colour, and ſlender Roots: Nor do I believe either Sort will alter, if they were cultivated ever ſo long.

The Root and Seed of the firſt Sort is ſometimes uſed in Medicine; but it is ſeldom cultivated in Gardens, the Markets being ſupplied from the Fields; yet the Druggiſts do commonly ſell the Seeds of the Garden Kind for it, which they may purchaſe at an eaſy Price, when it is too old to grow.

The ſecond Sort is cultivated in Kitchen Gardens, the Roots of which are large, ſweet, and accounted very nouriſhing: They are propagated by Seeds, which ſhould be ſown in *February* or *March*, in a rich mellow Soil, which muſt be well dug, that the Roots may run downward; their greateſt Excellency being the Length and Bigneſs of the Roots. Theſe may be ſown alone, or with *Carrots*, as is practiſed by the Kitchen-Gardeners near *London*, ſome of whom do alſo mix *Leeks*, *Onions* and *Lettuce* with their *Parſnips*: But this I think very wrong; for it is not poſſible that ſo many different Sorts can thrive well together, except they are allowed a conſiderable Diſtance; and if ſo, it will be equally the ſame to ſow the different Sorts ſeparate. However, *Carrots* and *Parſnips* may be ſown together very well, eſpecially where the *Carrots* are deſigned to be drawn off young; becauſe the *Parſnips* do generally ſpread moſt towards the latter End of Summer, which is after the *Carrots* are gone; ſo that there may be a double Crop upon the ſame Ground.

When the Plants are come up, you ſhould hough them out, leaving them about ten Inches or a Foot aſunder; obſerving at the ſame time to cut up all the Weeds, which, if permitted to grow, would ſoon over-bear the Plants, and choak them: This muſt be repeated three or four times in the *Spring*, according as you find the Weeds grow: But in the latter Part of *Summer*, when the Plants are ſo ſtrong as to cover the Ground, they will prevent the Growth of Weeds; ſo that after that Seaſon they will require no farther Care.

When the Leaves begin to decay, the Roots may be dug up for Uſe, before which Time they are ſeldom well-taſted; nor are they good for much late in the *Spring*, after they are ſhot out again: So that thoſe who would preſerve thoſe Roots for *Spring* Uſe, ſhould dig them up in the Beginning of *February*, and bury them in Sand, in a dry Place, where they will remain good until the Middle of *April*, or later.

If you intend to ſave the Seeds of this Plant, you ſhould make choice of ſome of the longeſt, ſtraiteſt and largeſt Roots, which ſhould be planted about two Feet aſunder, in ſome Place where they may be defended from the ſtrong South and Weſt Winds; for the Stems of theſe Plants do commonly grow to a great Height, and are very ſubject to be broken by ſtrong Winds, if expoſed thereto: They ſhould be conſtantly kept clear from Weeds; and if the Seaſon ſhould prove very dry, you muſt give them ſome Water twice a Week, which will cauſe them to produce a greater Quantity of Seeds; which will be much ſtronger than if they were wholly neglected. Toward the latter End of *Auguſt*, or the Beginning of *September*, the Seeds will be ripe, at which Time you ſhould carefully cut off the Heads, and ſpread them upon a coarſe Cloth for two or three Days, to dry; after which the Seeds ſhould be beaten off, and put up for Uſe: But you muſt never truſt to theſe Seeds after they are a Year old; for they will ſeldom grow beyond that Age.

The third Sort is preſerved in Botanic Gardens, among ſome other Sorts of theſe Plants, for Variety, but is ſeldom propagated for Uſe: This is by many ſuppoſed to be the *Panaces Syriacum* of the Antients, from whence the *Opoponax* is taken, which is ſuppoſed to be the concrete Juice of this Plant: As is the *Aſſa Fœtida* ſuppoſed to be the concrete Juice of one Species of this Plant.

All theſe Sorts may be cultivated by ſowing their Seeds early in the *Spring*, or in *Autumn*, ſoon after they are ripe, and ſhould be managed as the Garden Kind, with this difference, *viz.* the Plants ſhould not ſtand nearer than two Feet and an half Diſtance; but then they need not be reduced to this until the ſucceeding *Spring*. Theſe Roots are perenniel, and may be removed with Safety at any time after their Leaves are decayed: They ſeldom produce Seeds until the third Year after they are ſown.

PASTURE.

Paſture Ground is of two Sorts, the one is Low Meadow-land, which is often overflowed, and the other is Up-land Paſture, which lies high and dry. The firſt of theſe will produce a much greater Quantity of Hay than the latter, and will not require manuring or feeding ſo often: But then the Hay produced on the Upland is much preferable to the other, as is alſo the Meat which is fed on the Upland, more valued than that which is fatted in rich Meadows: Though the latter will make the fatter and larger Cattle, as is ſeen by thoſe which are brought from the low rich Lands of *Lincolnſhire*. But where People are nice in their Meat, they will give a much larger Price for ſuch as hath been fed on the Downs, or in ſhort Up-land Paſture, than for the other, which is much larger. Beſides this, dry Paſtures have an Advantage over the Meadows, that they may be fed all the Winter: and are not ſo ſubject to poach in wet Weather; nor will there be ſo many bad Weeds produced, which are great Advantages, and do in a great meaſure recompenſe for the Smallneſs of the Crop.

I have already mentioned the Advantages of Meadow-land, or ſuch as is capable of being overflowed with Water, and given Directions for draining and improving low Paſture-land, under the Article of Land; ſo ſhall not repeat that here, but ſhall juſt mention ſome Methods for improving of Up-land Paſture.

The firſt Improvement of Up-land Paſture, is by fencing of it, and dividing it into ſmall Fields, of four, five, ſix, eight or ten Acres each, planting of Timber-trees in the Hedge-rows, which will ſcreen the Graſs from the drying pinching Winds of *March*, which prevents the Graſs from growing in large open Lands; ſo that if *April* proves a dry Month, the Land produces very little Hay; whereas in the ſheltered Fields, the Graſs will begin to grow early in *March*, ſo will cover the Ground, and prevent the Sun from parching the Roots of the Graſs, whereby it will be kept growing ſo as to afford a tolerable Crop, if the *Spring* ſhould prove dry. But in fencing of Land, it muſt be obſerved (as was before directed) not to make the Incloſures too ſmall, eſpecially where the Hedge-rows are planted with Trees; becauſe when the Trees are advanced to a conſiderable Height, they will ſpread over the Land; and where they are cloſe, will render the Graſs ſour, ſo that, inſtead of being an Advantage, it will greatly injure the Paſture.

The next Improvement of Up-land Paſtures, is to make the Turf good, where either from the Badneſs of the Soil, or for want of proper Care, the Graſs hath been deſtroyed by Ruſhes, Buſhes, or Mole-hills. Where the Surface of the Land is clayey and cold, it may be improved by paring of it off, and burning it in the Manner before directed; but if it is a hot ſandy Land, then *Chalk*, *Lime*, *Marle* or *Clay* are very proper Manures to lay upon it; but this ſhould be laid in pretty good Quantities, otherwiſe it will be of little Service to the Land.

If the Ground is over-run with Buſhes or Ruſhes, it will be a great Advantage to the Land to grub them up toward the latter Part of the *Summer*; and after they are dried, to burn them, and ſpread the Aſhes over the Ground juſt before the Autumnal Rains; at which Time the Surface of the Land ſhould be levelled, and ſown with Graſs-ſeed, which will come up in a ſhort time, and make good Graſs the following *Spring*. So alſo, where the Land is full of Mole-hills theſe ſhould be pared off, and either burnt for the Aſhes, or ſpread immediately on the Ground, when they are pared off, obſerving alſo to ſow the bare Patches with Graſs-ſeed, juſt as the Autumnal Rains begin.

Where the Land has been thus managed, it will be o great Service to roll the Turf, in the Months of *February* and *March*, with a heavy Wood-roller, always obſerving t do it in moiſt Weather, that the Roll may make an Impreſſion. This will render the Surface level, and make it much eaſier to mow the Graſs, than when the Ground lies i Hills; and will alſo cauſe the Turf to thicken, ſo as t have what the People uſually term a good Bottom. Th Graſs will alſo be the ſweeter for this Huſbandry, and it wil be a great Help to deſtroy bad Weeds.

Another Improvement of Up-land Paſtures, is the feeding of them; for where this is not practiſed, the Land mu be manured at leaſt every third Year; and where a Farme hath much arable Land in his Poſſeſſion, he will not care t part with his Manure to the Paſture. Therefore every Fa mer ſhould endeavour to proportion his Paſture to h arable Land, eſpecially where Manure is ſcarce, otherwi he will ſoon find his Error; for the Paſture is the Foundatio of all the Profit, which may ariſe from the arable Land.

Whenev

Whenever theſe Up-land paſtures are mended by Manure, there ſhould be a Regard had to the Nature of the Soil, and a proper Sort of Manure applied: as for Inſtance, all hot ſandy Lands ſhould have a cool Manure; Neats-dung and Swines-dung, are very proper for ſuch Lands: but for cold Lands, Horſe-dung, Aſhes, and other warm Manures are proper. And when theſe are applied, it ſhould be done in *Autumn*, before the Rains have ſoaked the Ground, and rendered it too ſoft to cart on; and it ſhould be carefully ſpread, breaking all the Clods as ſmall as poſſible, and then harrowed with Buſhes, to let it down to the Roots of the Graſs. When the Manure is laid on at this Seaſon, the Rains in *Winter* will waſh down the Salts, ſo that the following Spring the Graſs will receive the Advantage of it.

There ſhould alſo be great Care had to the deſtroying of Weeds in the paſture every *Spring* and *Autumn*; for where this is not practiſed, the Weeds will ripen their Seeds, which will ſpread over the Ground, and thereby fill it with ſuch a Crop of Weeds, as will ſoon over-bear the Graſs, and deſtroy it; and it will be very difficult to root them out, after they have gotten ſuch poſſeſſion: eſpecially Ragwort, and ſuch other Weeds as have Down adhering to their Seeds.

Theſe Up-land paſtures ſeldom degenerate the Graſs which is ſown on them, (if the Land is tolerably good) whereas the low Meadows which are overflowed in *Winter*, do in few Years turn to a harſh ruſhy Graſs, tho' the Up-land will continue a fine ſweet Graſs for many Years without renewing.

The Graſſes proper to ſow on theſe Up-land paſtures, are, *Rye-graſs*, *Clover*, *Trefoil*, *Nonſuch*, *Spurrey*, *St. Foyn* and *La Lucern*. The Manner of ſowing and cultivating all theſe, is exhibited under their proper *Articles*.

PAVIA, The Scarlet Flowering Horſe Cheſnut: *vulgo*.

The *Characters* are;

The Leaves are like thoſe of the Horſe-Cheſnut: *the Flower is of an anomalous Figure, and conſiſts of five Leaves, which are ſo diſpoſed as to reſemble a Lip Flower; the two uppermoſt are united, and form a ſort of Helmet; the three undermoſt appear ſomewhat like a Mouth gaping: theſe Flowers are diſpoſed into a Spike, and are of a beautiful ſcarlet Colour: the Ovary, which riſes in the Center of the Flower-cup, afterwards becomes an oblong pyramidal Fruit, divided into three Cells, in each of which is lodged one globular Seed.*

There is but one *Species* of this Tree, *viz.*

Pavia. *Boerh. Ind.* The Scarlet Flowering Horſe-Cheſnut: *vulgo*.

This Tree is a Native of *America*, from whence the Seeds were firſt brought into *Europe*: it grows in great Plenty in the Woods of *South Carolina*, but is very hardy, enduring the ſevereſt Cold of our Climate in the open Air.

It may be propagated by ſowing the Seeds in the *Spring*, upon a warm Border of light ſandy Earth; and when the Plants come up, they ſhould be carefully clear'd from Weeds: but they muſt not be tranſplanted until the *Spring* following, when they ſhould be removed juſt before they begin to ſhoot, and placed either in a Nurſery to be train'd up, or elſe into the Places where they are to remain; obſerving, if the Seaſon be dry, to water them until they have taken Root, as alſo to lay ſome Mulch upon the Surface of the Ground, to prevent the Sun and Wind from drying it too faſt: and as the Plants advance, ſo the lateral Branches ſhould be pruned off, in order to reduce them to regular Stems.

You muſt alſo obſerve to dig the Ground about their Roots every *Spring*, that it may be looſe, to admit the Fibres of the Roots, which, while young, are too tender to penetrate the Ground, if it be very hard.

With this Management the Plants will greatly advance, and in four or five Years will produce Flowers and Fruits, which in warm Seaſons are perfected enough to grow, ſo that the Plants may be multiplied therefrom very faſt.

This Tree may alſo be propagated by budding or inarching it upon the common *Horſe-Cheſnut*: but the Trees thus raiſed will never arrive to near the Size of thoſe which are produced from Seeds; nor will they grow near ſo faſt.

Such of theſe Trees as are raiſed from Seeds, if planted in a good Soil, will grow to be twenty-five or thirty Feet high, and produce great numbers of beautiful red Flowers, which commonly appear the Beginning of *June*; at which Seaſon it makes a beautiful Appearance amongſt other hardy Trees.

PEACH: *vide* Perſica.

PEAR: *vide* Pyrus.

PEASE: *vide* Piſum.

PEASE EVERLASTING: *vide* Lathyrus.

PEDICLE, is that Part of a Stalk which immediately ſuſtains the Leaf, a Flower, or a Fruit, and is commonly call'd a Foot-ſtalk.

PEDICULARIS, Rattle, Cocks-comb or Louſewort.

There are four different Kinds of this Plant, which grow wild in Paſtures in ſeveral Parts of *England*, and in ſome low Meadows are very troubleſome to the Paſtures; eſpecially one Sort with yellow Flowers, which riſes to be a Foot high or more, and is often in ſuch Plenty, as to be the moſt predominant Plant; but this is very bad Food for Cattle, and when it is mowed with the Graſs for Hay, renders it of little Value. The Seeds of this Plant are generally ripe by the Time the Graſs is mowed, ſo that whenever a Perſon takes Graſs-ſeed for ſowing, they ſhould be very careful, that none of this Seed is mixed with it. As theſe Plants are never cultivated, ſo I ſhall not trouble the Reader with their ſeveral Varieties.

PELECINUS.

The *Characters* are;

It hath a papilionaceous (or pea-bloom) Flower, out of whoſe Empalement riſes the Pointal, which afterward becomes a plain bicapſular and bivalve Pod, indented on each Side like a Saw, and filled with plain kidney-ſhaped Seeds.

We know but one *Species* of this Plant; (*viz.*)

Pelecinus *vulgaris. Inſt. R. H.* Common Pelecinus.

This plant is preſerved in Botanic Gardens, for the ſake of Variety: it is an annual Plant, ſo the Seeds ſhould be ſown early in *April*, on a Bed of light freſh Earth, in Drills about eighteen Inches aſunder; and when the Plants are come up, they ſhould be carefully cleared from Weeds; and where they are too cloſe, they ſhould be thinned, leaving them ſix or eight Inches Diſtance in the Rows, and obſerve always to keep them clear from Weeds, which is all the Culture they require. Theſe Plants ſpread on the Ground, and from the Wings of the upper Leaves; the Flowers are produced on ſlender Foot-ſtalks, which are ſmall, and of a dirty red Colour; theſe are ſucceeded by Pods, which are flat, and indented on both Sides, reſembling the Saw of the Saw-fiſh.

PELLITORY OF THE WALL: *vide* Parietaria.

PENDULOUS HEADS OF FLOWERS, are ſuch as hang downward.

PENNATED: A Pennated Leaf (call'd in *Latin*, *Folium Pennatum*) is a compound Leaf, divided into ſeveral Parts, (each of which is call'd a *Lobe*) placed along the middle Rib, either alternately, or by Pairs. When the middle Rib is terminated by an odd Lobe, it is ſaid to be unequally pennated; and equally pennated, when it is not terminated by an odd Lobe. When the Lobes are all nearly of the ſame Form and Bigneſs, it is call'd, an Uniform pennated Leaf; when they are not ſo, it is ſaid to be Difform. Examples of pennated Leaves, are the *Aſh*, *Walnut*, &c.

PENNY-ROYAL: *vide* Pulegium.

PENTAPETALOUS FLOWEFS, are ſuch as have five Leaves.

PENTAPHYLLOIDES, [of πέντε, *five*, φύλλον, a *Leaf*, and εἶδος, *Form*] Baſtard Cinquefoil.

The *Characters* are;

It hath pennated Leaves, conſiſting of ſeveral Lobes placed along the middle Rib, and terminated by an odd Lobe, in which it differs from the Cinquefoil; *the Flower conſiſts of five Leaves, which expand in form of a* Roſe, *and are ſucceeded by Hemiſpherical Seed-veſſels, which contain many ſmall Seeds.*

The *Species are* ;

1. PENTAPHYLLOIDES *Argentina dicta. Raii Syn.* Wild Tanſey *or* Silver-weed.
2. PENTAPHYLLOIDES *fruticoſum. Raii Syn.* Shrub Cinquefoil.

The firſt of theſe Plants is very common in moiſt Meadows, and by the Sides of Ditches, in divers Parts of *England*, and is rarely cultivated in Gardens ; for the Branches of theſe Plants trail upon the Ground, and take Root at their Joints, ſo that in a ſhort time, a few of theſe Plants would over-run a whole Garden. This Herb is uſed in Medicine ; for which purpoſe it is gather'd in the Fields, and brought to Market, by ſuch Perſons who make it their Buſineſs to gather wild Plants.

The ſecond Sort grows to be four or five Feet high, and may be train'd to a regular Head. This is a very proper Shrub to intermix with others of the ſame Growth, in ſmall Wilderneſs Quarters, where it will make a pretty Diverſity, and continues flowering a long time.

This is propagated either by Suckers or Layers, which may be obtain'd in great Plenty ; for it generally produces a great number of Shoots from the Bottom, which when they come out near the Ground, may be earth'd up, or laid down therein ; and if they are water'd in dry Weather, will take Root in a ſhort time ; when they may be taken off, and tranſplanted where they are to remain. The beſt Time to tranſplant them is in *October* or *February :* they delight in a moiſt Soil ; tho' they will grow in almoſt any Soil or Situation.

There are ſeveral other *Species* of this Plant, which are preſerved in ſeveral curious *Botanick* Gardens for Variety ; but as they are Plants of little Beauty or Uſe, ſo I ſhall not enumerate them here.

PEONY : *vide* Pæony.

PEPO, [takes its Name of πεπαίνεσθαι to *ripen*, becauſe the Fruit of this Plant ripens very readily] Pumpion.

The *Characters* are ;

The Flower conſiſts of one Leaf; which is Bell-ſhaped, expanded at the Top, and cut into ſeveral Segments : of theſe Flowers ſome are Male, and ſome are Female, as in the Cucumbers *and* Melons : *The Female Flowers grow upon the Top of the* Embryo, *which afterwards becomes an oblong or round fleſhy Fruit, having ſometimes a hard, rugged, or uneven Rind, with Knobs and Furrows, and is often divided into three Parts, incloſing flat Seeds, that are edged or rimmed about as it were with a Ring, and fix'd to a ſpungy* Placenta.

The *Species* are ;

1. PEPO *oblongus. C. B. P.* The greater oblong Pumpion.
2. PEPO *vulgaris. Raii Hiſt.* The common Pumpion.
3. PEPO *rotundus Aurantii forma. C. B. P.* Orange-ſhaped Pumpion.
4. PEPO *fructu parvo, pyriformi. Tourn.* Pear-ſhaped Pumpion.
5. PEPO *fructu minimo ſphærico. Tourn.* Pumpion, with a very ſmall ſpherical Fruit.

There are ſeveral other Varieties of theſe Fruits, which ſeem to be only ſeminal Variations ; ſo that it would be needleſs to mention them all in this Place, ſince the Seeds taken from any one of the Sorts will not continue the ſame three Years together, if ſown in the ſame Garden, as I have ſeveral times experienced.

The two firſt Sorts are by ſome Perſons cultivated for their Fruit ; which, when ripe, they cut open, and take out the Seeds, and then ſlice ſome Apples into the Shell, mixing them with the Pulp of the Fruit and Sugar : this they bake in an Oven, and afterwards eat it ſpread upon Bread ; but it is too ſtrong for Perſons of weak Stomachs, and only proper for Country People, who uſe much Exerciſe.

The Seeds of theſe Plants are uſed as one of the four cold Seeds in Medicine.

The other Sorts are preſerved by ſome curious Perſons, for Variety, but are of little Uſe, being good for nothing when grown old ; but while they are very ſmall, ſome Perſons gather and boil them, like *Turnips*, or as they do the *Squaſhes*, and are very fond of them.

Theſe may be propagated in the ſame Manner as was directed for the *Gourds*, to which I ſhall refer the Reader, to avoid Repetition.

PERENNIAL PLANTS, are ſuch whoſe Roots will abide many Years, whether they retain their Leaves in Winter or not : thoſe which do retain their Leaves, are call'd *Evergreens* ; but ſuch as caſt their Leaves, are call'd *Deciduous* or *Perdiſols*.

PERESKIA, Gooſeberry *vulgò*.

The *Characters* are ;

It hath a roſe-ſhaped Flower conſiſting of ſeveral Leaves, which are placed orbicularly ; whoſe Cup afterward becomes a ſoft fleſhy globular Fruit, beſet with Leaves ; in the Middle of the Fruit, are many flat roundiſh Seeds, included in a Mucilage.

We know but one *Species* of this Plant ; *(viz.)*

PERESKIA *aculeata, flore albo, fructu flaveſcente. Plum. Nov. Gen.* Prickly *Pereskia*, with a white Flower, and a yellowiſh Fruit.

This Plant grows in ſome Parts of the *Spaniſh-Weſt-Indies*, from whence it was brought to the *Engliſh* Settlements in *America*, where it is called a Gooſeberry, and by the *Dutch* it is called Blad-Apple. This Plant hath many ſlender Branches, which will not ſupport themſelves, ſo muſt be ſupported by Stakes, otherwiſe they will trail on whatever Plants grow near them. Theſe Branches, as alſo the Stem of the Plant, are beſet with long whitiſh Spines, which are produced in Tufts. The Leaves are roundiſh, very thick and ſucculent, and the Fruit is about the Size of a Walnut, having Tufts of ſmall Leaves on it, and hath a whitiſh mucilaginous Pulp.

It may be propagated by planting of the Cuttings during any of the *Summer* Months : theſe Cuttings ſhould be planted in Pots filled with freſh light Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun in the Heat of the Day, as alſo to refreſh them every third or fourth Day with Water. In about two Months the Cuttings will have made good Roots, when they may be carefully taken out of the Pots, and each planted in a ſeparate Pot filled with freſh Earth, and then plunged into the Hot-bed again, where they may remain during the *Summer* Seaſon ; but at *Michaelmas*, when the Nights begin to be cold, they ſhould be removed into the Stove, and plunged into the Bark-bed. During the *Winter* Seaſon, the Plants muſt be kept warm, and ſhould be watered twice a Week ; but in cold Weather it ſhould not be given to them in large Quantities. In *Summer* they muſt have a large Share of Air, and muſt be more plentifully watered : but they ſhould conſtantly remain in the Stove ; for tho' they will bear the open Air in *Summer*, in a warm Situation, yet they will make no Progreſs, if they are placed abroad ; nor do they thrive ſo well in the Dry-ſtove, as when they are plunged in the Tan : ſo that the beſt Way is to ſet them next a Trellice, at the Back of the Tan-bed, to which their Branches may be faſtened, to prevent their trailing on other Plants. This Plant has not as yet produced either Flowers or Fruit in *England* ; but as there are ſeveral Plants pretty well grown, in the Gardens of the Curious, ſo we may expect ſome of them will flower in a ſhort Time.

PERICLYMENUM [Περικλύμενον, of περὶ, *about*, and κυλίω, to *roll*, becauſe the Branches of theſe Plants roll or twiſt themſelves round ſuch Plants as grow near them] Trumpet-Honeyſuckle : *vulgo*.

The *Characters* are ;

It hath the whole Appearance of the Honeyſuckle, *(from which it differs in the Shape of the Flower) which is tubuloſe or Bell-ſhaped, and expands at the Top, where it is cut into ſeveral almoſt equal Segments.*

PERICLYMENUM *Virginianum, ſemper-virens & florens. H. L.* Virginian Scarlet Honeyſuckle : *vulgo*.

This Shrub is greatly eſteem'd for the Beauty of its Flowers, which are of a fine Scarlet Colour ; the Leaves continue all the Year green, and it continues flowering moſt Par of the *Summer*.

It may be propagated by laying down the tender Branch in the *Spring*, obſerving in dry Weather to refreſh them wit Water, which will greatly facilitate their Rooting : th *Spring* following, they will be fit to tranſplant ; when the ſhould be cut off from the old Plants, and carefully take up, ſo as not to injure their Roots. The beſt Time to r move them is in *March*, juſt before they ſhoot out ; but yo muſt obſerve, if the Seaſon ſhould prove dry, to water them an and lay a little Mulch upon the Surface of the Ground near their Stems, to prevent their Ground from drying too faſt. It ſhould have a ſtrong Soil, and be expoſed to the South-Eaſt Sun, but muſt have the Aſſiſtance of a Wall or Pale to ſupport the Branches, otherwiſe they will trail upon the Ground.

This Plant, altho' a Native of *Virginia*, yet if planted in a clear Air, will endure the ſevereſt Cold of our Climate very well; but it will not thrive in cloſe Places, or too near the City, the Smoak ariſing from the Sea-coal Fires being very pernicious to it.

To this *Article* muſt be added,

1. Periclymenum *racemoſum, flore flaveſcente, fructu niveo. Plum. Tab. Hort. Elth.* Branching Trumpet Honey-ſuckle, with a yellowiſh Flower, and a ſnowy Fruit, commonly called in *Barbadoes*, Snowberry-buſh.

2. Periclymenum *arboreſcens, ramulis inflexis, flore luteo. Plum. Cat.* Tree-like Trumpet Honey-ſuckle, with a yellow Flower.

3. Periclymenum *aliud arboreſcens, ramulis inflexis, flore corallino. Plum. Cat.* Tree like Trumpet Honey-ſuckle, with a coralline Flower.

The firſt of theſe Plants is pretty common in *Barbadoes* and *Jamaica*, where the Inhabitants give it the Name of Snowberry-buſh, from the extreme Whiteneſs of the Fruit. The ſecond and third Sorts where diſcovered by Father *Plumier* in ſome of the *French* Settlements in *America*; and ſince by the late Dr. *Houſtoun* at *La Vera Cruz*.

Theſe are all of them very tender Plants, ſo muſt conſtantly remain in the Bark-ſtove, otherwiſe they will not thrive in this Country. They may be propogated by Seeds, which ſhould be brought over either in Sand or Earth, otherwiſe they ſeldom ſucceed; when they arrive, the Tubs of Earth, in which the Seeds were ſown, ſhould be plunged into a Hot-bed of Tanners-bark, obſerving frequently to water them: and when the Plants are come up, they ſhould be carefully tranſplanted into ſeparate ſmall Pots filled with rich freſh Earth, and plunged into the Hot-bed again; where they may remain till about *Michaelmas*, when they ſhould be plunged into the Bark-bed in the Stove, and treated as other tender exotic Plants from the ſame Countries; and in two or three Years the Plants will flower, when they will make an agreeable Variety.

PERIPLOCA, [Περιπλοκὴ, of περὶ, *about*, and πλοκη a *knitting* or *plaiting*, becauſe this Plant entangles itſelf with itſelf, or any other neighbouring Plants] Virginian Silk or climbing Dog's bane: *vlgo.*

The *Characters* are;

The Flower conſiſts of one Leaf, which is more expanded at the Brim than thoſe of the Apocynum; *che Pointal which riſes in the Center of the Flower-cup, becomes a Fruit ſo nearly reſembling that of the* Apocynum, *as not to be diſtingniſh'd therefrom, but by very curious Obſervers: to which ſhould be added, it hath climbing Stalks.*

The *Species* are;

1. Periploca *foliis oblongis. Tourn.* Periploca with oblong Leaves.

2. Periploca *Monſpeliaca, foliis rotundioribus. Tourn.* Periploca of *Montpellier*, with rounder Leaves.

3. Periploca *foliis oblongis anguſtioribus. Inſt. R. H.* Longer and narrower-leaved *Virginian* Silk, or Climbing Dogs-bane.

4. Periploca *Monſpeliaca, foliis acutioribus. Inſt. R. H.* Climbing Dogs-bane of *Montpelier*, with ſharp pointed Leaves.

5. Periploca *Americana, fructu molliter echinato. Inſt. R. H. American* Climbing Dogs-bane, with a prickly Fruit.

6. Periploca *Americana latifolia, ſiliqua dura oblonga, tumida & glabra. Inſt. R. H.* Broad-leaved *American* Climbing Dogs-bane, with a long hard ſmooth ſwelling Pod.

7. Periploca *Americana ſcandens, ſalicis anguſtiſſimo folio, flore albo. Plum.* Climbing *American* Dogs-bane, with a narrow willow Leaf, and a white Flower.

8. Periploca *Americana repens umbellata, foliis citri, flore coccineo. Plum.* Creeping *American* Dogs-bane, with a citron Leaf, and ſcarlet Flowers, growing in an Umbel.

9. Periploca *Americana ſcandens, folio citri, fructu maximo. Plum.* Climbing *American* Dogs-bane, with a citron Leaf, and a large Fruit.

10. Periploca *Americana ſcandens, folio convolvuli, fructu alato. Plum. American* climbing Dogs-bane, with a convolvulus Leaf, and a winged Fruit.

The two firſt are all I have obſerved in the *Engliſh* Gardens: the firſt is very common in *England*, but the latter is, at preſent, pretty rare.

Theſe may be propagated by laying down their Branches in the Spring, which will take Root in a Year's time; when they may be taken off, and tranſplanted where they are to remain: which ſhould be either againſt a lofty Wall or Building, or elſe placed in Wilderneſs Quarters amongſt other tall Flower-trees, where they ſhould be ſupported by ſtrong Poles, about which theſe Plants will twine, and riſe to a great Height. Theſe two Sorts are hardy, and will endure the Cold of our Winters very well, provided they are planted in a dry Soil.

They produce their Flowers in *June* and *July*, but do rarely perfect their Seeds in *England*. Their Flowers are not very beautiful; but, for their Oddneſs, may have a Place amongſt other hardy Shrubs in every good Garden.

The third and fourth Sorts are hardy Plants, which will live in the open Air in this Country. Theſe may be propagated by laying down of their Branches (for they very rarely produce good Seeds in *England*;) theſe may be treated in the ſame Manner as the two firſt.

The ſix laſt Sorts are tender, being Natives of the warm Parts of *America*. The Seeds of all theſe Sorts were ſent to *England* by the late Dr. *Houſtoun*, who collected them in *Jamaica*, at *Campechy*, and *Carthagena*; where they grow in great Plenty, and twiſt themſelves round whatever Trees grow near them, and ſome of them riſe to the Height of forty or fifty Feet or more. Some of theſe Sorts produce very large warted Pods, which are full of oblong flat Seeds, to which is faſtened a very long ſoft white Down, which helps to convey the Seeds to a great Diſtance when ripe. This Down, as alſo that of the *Apocynum*, have of late Years been uſed to ſtuff Pillows, Matraſſes and Quilts, for which Purpoſes there is nothing ſo proper; for it is ſo exceedingly light, that a Quilt of great Thickneſs is hardly to be felt, when ſpread over a Bed; which is of great Advantage to thoſe Perſons who are troubled with the Gout, and cannot bear any Weight on the Part affected. It hath alſo a very great Elaſticity, ſo that it is not apt to ſtick together. This Down is called in *French*, *de la Wadde*, and is greatly in uſe amongſt the Quality in *France*.

All theſe Plants may be propagated by Seeds, which ſhould be ſown on a Hot-bed early in the Spring; and when the Plants are fit to tranſplant, they ſhould be each planted into a ſeparate Pot filled with freſh Earth, and plunged into a moderate Hot-bed of Tanners-bark, obſerving to ſhade them from the Sun every day, until they have taken new Root; after which Time, they ſhould have a large Share of Air in warm Weather, and muſt have Plenty of Water. In about ſix Weeks or two Months after planting, the Plants will get up to reach the Glaſſes of the Hot-bed; when they would be ſhifted into larger Pots, and plunged into the Bark-bed in the Stove; where they muſt be ſupported by an Eſpalier, otherwiſe they will twiſt themſelves round whatever Plants grow near them.

Theſe Plants will bear the open Air in Summer, but they never make any Progreſs, when they are expoſed, and rarely flower; therefore in order to have theſe Plants in Beauty, they ſhould conſtantly remain in the Stove, and muſt have a large Share of free Air in mild Weather. When they are thus managed, they will riſe to the Height of thirty Feet or more, and will produce Flowers every Summer.

PERIWINCLE: *vide* Pervinca.

PERSEA, The Avocado or Avogato Pear.

The *Characters* are;

It hath a roſe-ſhap'd Flower, conſiſting of ſeveral Leaves, which are ranged in a Circle; from whoſe Middle riſes the Pointal, which afterwards becomes a ſoft fleſhy pear-ſhaped Fruit, in which is a hard Stone or Seed, having two Lobes, which is included in a Membrane or Pericardium.

We know but one *Species* of this Plant; (*viz.*)

Persea. *Cluſ. Hiſt.* The Avocado or Avogato Pear.

This Tree grows in great Plenty in the *Spaniſh Weſt-Indies*, as alſo in the *Iſland* of *Jamaica*, and hath been tranſplanted into moſt of the *Engliſh* Settlements in the *Weſt-Indies*, on account of its Fruit, which is not only eſteemed ed by the Inhabitants as a Fruit to be eaten by way of Deſert, but is very neceſſary for the Support of Life. The Fruit is of itſelf very inſipid, for which Reaſon they generally eat it with the Juice of Lemons and Sugar to give it a Piquancy. It is very nouriſhing, and is reckoned a great Incentive to Venery. Some People eat this Fruit with Vinegar and Pepper.

This Tree in the warm Countries, where it is planted, grows to the Height of thirty Feet or more, and has a Trunk as large as our common Apple-trees; the Bark is ſmooth, and of an Aſh-colour. The Branches are beſet with pretty large oblong ſmooth Leaves, which are of a deep green Colour, and continue on the Tree throughout the Year. The Flowers and Fruit are, for the moſt part, produced toward the Extremity of the Branches.

In *Europe* this Plant is preſerved as a Curioſity, by thoſe Perſons who are ſkilful in collecting exotic Plants: and tho' there is little Hope of its producing Fruit, yet for the Beauty of its ſhining green Leaves, which continue thro' the Winter, it deſerves a Place in every curious Collection of Plants.

It is propagated by Seeds, which ſhould be obtained as freſh as poſſible from the countries of its Growth; and if they are brought over in Sand, they will be more likely to grow, than ſuch as are brought over dry. Theſe Nuts or Seeds ſhould be planted in Pots, filled with light rich Earth, and plunged into a Hot-bed of Tanners-bark, which ſhould be kept pretty warm, by covering of the Glaſſes of the Bed every Night with Mats or Straw, eſpecially when the Nights are cold. The Pots ſhould alſo be frequently watered, when the Earth appears dry, which will greatly facilitate the Vegetation of the Seed, provided the Water is not given in large Quantities, which would rot them. In about a Month or five Weeks the Plants will come up, when they muſt be treated very tenderly; for the Bed muſt be kept in a due Temperature for Heat; and when the Days prove warm, the freſh Air ſhould be admitted to the Plants, by raiſing of the Glaſſes a little. The Plants muſt alſo be frequently watered. When the Plants have grown about four Inches high, they ſhould be carefully tranſplanted; and where there are ſeveral Plants in one Pot, they muſt be parted, being careful to preſerve a Ball of Earth to the Root of each, and planted into ſeparate ſmall Pots filled with light rich Earth, and then plunged into a Hotbed of Tanners-Bark; obſerving to ſhade them until they have taken new Root; after which Time they ſhould have freſh Air admitted to them, in proportion to the Warmth of the Seaſon, and they muſt be duly watered. Towards *Michaelmas* the Plants muſt be removed into the Stove, and plunged into the Bark-bed, where, during the winter Seaſon, they ſhould be kept very warm, and muſt be gently watered twice a Week. In the Spring the Plants ſhould be ſhifted into Pots a Size larger than the former, and the Bark-bed ſhould be then renewed with freſh Tan, which will ſet the Plants in a growing State early, whereby they will make a fine Progreſs the following Summer. The Plants muſt be conſtantly kept in the Stove, for they are too tender to bear the open Air in this Country at any Seaſon.

PERSICA, [ſo call'd of *Perſia* in *Aſia*, from whence this kind of Plant was brought into our Climate] The Peach-Tree.

The *Characters* are;

It hath long narrow Leaves; the Flower conſiſts of ſeveral Leaves, which are placed in a circular Order, and expand in form of a Roſe; *the Pointal which riſes from the Center of the Flower-cup, becomes a roundiſh fleſhy Fruit, having a longitudinal Furrow, incloſing a rough rugged Stone, which is deeply furrow'd, by which it is diſtinguiſh'd from the* Almond.

There are a great Variety of theſe Trees, which are cultivated in the Gardens of thoſe who are curious in collecting the ſeveral Sorts of Fruit in the different Parts of *Europe*: I ſhall therefore firſt beg Leave to mention two or three Sorts, which are cultivated for the Beauty of their Flowers: after which, I ſhall enumerate the ſeveral Sorts of good Fruit which have come to my Knowledge.

1. Persica *vulgaris, flore pleno. Tourn.* Peach-Tree, with double Flowers.
2. Persica *Africana nana, flore incarnato ſimplici. Tourn.* Dwarf-Almond, with ſingle Flowers: *vulgo.*
3. Persica *Africana nana, flore incarnato pleno. Tourn.* Double-flowering Dwarf-Almond; *vulgo.*

The firſt of theſe Trees is a very great Ornament in a Garden early in the Spring, the Flowers being very large, double, and of a beautiful red or purple Colour. This may be planted in Standards, and if intermix'd amongſt other Flowering-Trees of the ſame Growth, makes a very agreeable Variety: or it may be planted againſt the Walls of the Pleaſure-Garden, where the beautiful Appearance of its Flowers early in the Spring will be more acceptable in ſuch Places than the choiceſt Fruits, which muſt be expoſed to Servants, and others, ſo that they ſeldom can be preſerved in large Families until they are ripe. This Tree may be propagated by budding it on the *Almond* or *Plum* Stocks, in the ſame Manner as the other Sort of *Peaches*, and ſhould be planted in a good freſh Soil that is not over-moiſt.

The other two Sorts are of humbler Growth, ſeldom riſing above five Feet high: theſe may be budded upon *Almond-Stocks*, or propagated by *Layers*; they will alſo take upon *Plum-Stocks*; but they are very apt to canker, after they have ſtood four or five Years upon thoſe Stocks, eſpecially that with double Flowers, which is tenderer than the other.

Theſe Shrubs make a very agreeable Variety amongſt low Flowering-Trees, in ſmall Wilderneſs Quarters. The ſingle Sort flowers in the Beginning of *April*, and the double is commonly a Fortnight later.

I ſhall now proceed to mention the ſeveral Sorts of good *Peaches* which have come to my Knowledge; and tho', perhaps, a greater number of Sorts may be found in ſome Catalogues of Fruits, yet I doubt whether many of them are not the ſame Kinds call'd by different Names: for, in order to determine the various Sorts, it is neceſſary to obſerve the Shape and Size of the Flowers, as well as the different Parts of the Fruit; for this does ſometimes determine the Kind, when the Fruit alone is not ſufficient: beſides, there is a vaſt Difference in the Size and Flavour of the ſame *Peach*, when planted on different Soils and Aſpects; ſo that it is almoſt impoſſible for a Perſon who is very converſant with theſe Fruits to diſtinguiſh them, when brought from various Gardens.

The preſent Confuſion of the Names of Fruits hath been many times owing to the bringing over Trees from *France*; for the Perſons who are generally employed to bring over thoſe Trees for Sale, are intirely ignorant of their various Sorts, and do themſelves take them upon Truſt, from the Perſons who make it their Buſineſs to propagate great Quantities, to ſupply the Markets of *France*, whither they are brought in Waggons, and ſold out in Parcels to thoſe Perſons who bring them into *England*. It alſo happens many times, if they are received by right Names, that theſe, in Length of Time, are loſt, or the Trees come into the Poſſeſſion of other Perſons, who not knowing the true Name of the Fruit, do often give them new Names, whereby there is ſuch a Confuſion in the Names of Fruit, as is impoſſible to rectify: And hence ſome Perſons have ſuppoſed a much greater Variety of *Peaches* than there is in Reality; tho' as the greateſt Part of theſe have been obtained from Seeds, ſo their Varieties may be multiplied annually, until there be no End of the Sorts. However, I ſhall content myſelf with enumerating the principal Sorts not known in *England*, which are ſufficient for any Gentleman to make a Collection to continue thro' the whole Seaſon of Fruit.

1. The *White Nutmeg* (called by the *French Petit-avant-peſche)* is the firſt ripe *Peach*; its Juice is muſky, if well expoſed, and is ripe the Beginning of *July*; it is a great Bearer, and if planted in two different Aſpects, the Fruit may be continued three Weeks in Perfection, otherwiſe it is ſoon gone after it is ripe, as is the Caſe with moſt other *Summer* Fruits. This ſhould have a *South Eaſt* and *South Weſt* Aſpect.

2. The *Red Nutmeg* (or *La Peſche de Troy)* is ripe towards the End of *July*. This is a great Bearer, and, if well expoſed, is an extraordinary good Fruit; it is ſomewhat larger than the White, and is of a beautiful red Colour towards the Sun.

3. The *Yellow Alberge* ripens ſoon after the *Red Nutmeg*, but is not eſteemed ſo good a Fruit; it is generally a good Bearer; the Fleſh is yellow within; and for Variety, there may be one Tree planted, where there is Room enough.

4. The *Red Magdalaine* (or *Magdalene Rouge)* is a middle-ſized Fruit; the Fleſh or Pulp is very delicious; it parts from the Stone where the Fleſh is red, and the Tree is a good Bearer. This ripens the Beginning of *Auguſt*, and ſhould have a *South* or *South-Eaſt* Aſpect.

5. The *White Magdalaine* (or *Magdalene Blanche)* is a fine large Fruit, when planted in a good Soil; the Fleſh is white, except near the Stone, where it is of a reddiſh Co-

lour; it is very full of a rich viny Juice, and eaſily melts in the Mouth; it is a great Bearer, but is very ſubject to drop its Fruit, and is often invaded by Inſects, as are many other Sorts of rich *Peaches*. This ripens the Beginning of *Auguſt*.

6. The *Mignonne* (or, as it is commonly called, *Minion*) *Peach*, is an excellent fine Fruit; the Side next the Sun is of a beautiful red Colour, as is alſo the Fleſh next the Stone; the Pulp is very firm, and full of a rich Juice; it is a plentiful Bearer, and ripens the Beginning of *Auguſt*.

7. The *Italian Peach* (or *Peſche d' Italie*) is of an oval Shape, ſomewhat pointed; the Fleſh is very delicate, and full of Juice, and red towards the Stone, which is flat, and ſharp-pointed; it is a good Bearer, a hardy *Peach*, and ripens the Middle of *Auguſt*.

8. The *Early Newington* (or *Smith's Newington*) is a very good *Peach*; the Pulp is firm, of a rich ſugary Flavour, and cloſely adheres to the Stone: this is very red on the Side next the Sun, as is alſo the Fleſh near the Stone. This ripens the Beginning of *Auguſt*.

9. *Les Druſelles* (or *Druſel Peach*) is of an oval Shape; the Skin is of a ſoft purple Colour next the Sun; the Fleſh is red and dry, but of a very agreeable Flavour. This ripens the End of *Auguſt*.

10. The *Nobleſs* (or *Nobleſt*) is a fair large *Peach*; the Fleſh comes clean from the Stone; the Pulp is melting, and full of a delicious Juice, and is of a reddiſh Colour next the Stone: It is a good Bearer, and ripens the Beginning of *Auguſt*.

11. *La Chevreuſe* (or *Belle Chevreuſe*) is of a bright red Colour next the Sun; the Fruit is longiſh, and pretty large; the Pulp is full of a delicate ſweet Juice, and ripens the latter End of *Auguſt*.

12. The *Chancellor* (or *Peſche Chanceliere*) was raiſed from the Stone of the *Chevreuſe Peach*, in the Gardens of the Chancellor *Seguire* in *France*, from whence it had its Name: It is a very large fair Fruit, full of a delicate ſugary Juice, and is eſteemed among the beſt Sort of *Peaches* in *France*. It ripens the End of *Auguſt*.

13. The *Montauban* is a fair handſome *Peach*, of a deep red Colour on the Side next the Sun, but of a pale green next the Wall; the Fleſh is melting, and parts from the Stone, where it is of a faint red Colour. This is a very good Bearer, and ripens the Beginning of *Auguſt*.

14. The *Royal George Peach*: this is a middle-ſized Fruit, pretty round, with a deep Furrow running Lengthwiſe: It is of a dark red Colour on the Side next the Sun, and of a paler Colour next the Wall; the Skin is covered over with a downy Subſtance, and is full of red Spots; the Fleſh is melting, of a delicate Flavour, and of a yellowiſh Caſt; the Stone is large, and of a deep red Colour. This ripens the latter End of *Auguſt*.

15. The *Nivette Peach* is of a middling Size, of an oval or oblong Shape, a little compreſſed on the Sides; it is of a yellowiſh Colour, marbled with red, and covered with a ſoft downy Subſtance; the Fleſh is ſoft, melting, of a yellow Colour, and parts from the Stone; the Juice is very rich: It ripens the Beginning of *September*.

16. The *Violet Peach* (or *Peſche Violette*) is ſomewhat long, of a middle Size; the Pulp is melting, and its Juice of a vinous Flavour. This is by the *French* eſteemed the Queen of Fruits. It ripens towards the End of *Auguſt*, and is a plentiful Bearer.

17. The *Portugal Peach* is a fair, large, beautiful Fruit, of a deep red Colour towards the Sun, which fades off to a light green next the Wall; the Skin has a ſoft Down upon it, and is pretty full of red Spots; the Fleſh is very firm, of a rich vinous Flavour, and adheres cloſely to the Stone, which is ſmall for the Size of the Fruit, but very rough. This ripens the Beginning of *September*.

18. The *Purple Alberge* (or *La Peſche Alberge Violette*) is a middle-ſized Fruit, of a dark purple or Violet Colour on the Side next the Sun, which goes off to a dark red next the Wall; the Fleſh is yellow, and parts from the Stone, where it is red; it is full of a rich vinous Juice, and ripens towards the End of *Auguſt*.

19. The *Old Newington* is eſteemed one of the beſt *Peaches* in *England*; it is a fair large Fruit, of a lively red Colour next the Sun, which goes off to a yellowiſh green next the Wall; the Fleſh is firm, and cloſely adheres to the Stone; it is full of a delicious rich Juice, and of a deep red next the Stone. This is accounted an indifferent Bearer, which is wholly owing to its Management in pruning; for I have had it bear extremely well in a Standard, and the Fruit has been deeper coloured, and of richer Flavour than thoſe againſt Walls.

20. *La Teton de Venus* (or *Venus's Breaſt*) is a middle-ſized Fruit, rather long than round, having a very deep Sulcus or Furrow, which divides it like a double Fruit; the two Sides of which riſe ſomewhat like a Woman's Breaſt, from whence it had its Name; the Fleſh is very white, with a little Bluſh of red next the Sun; it is melting, and full of a high-flavoured Juice. This ripens the latter End of *Auguſt*.

21. *La Peſche pourpree* (or *purple Peach*) is a fair round Fruit, of a dark red Colour next the Sun, which goes off to a paler red next the Wall; the Fleſh next the Stone is very red; the Juice is of a moſt delicious Flavour, when the Fruit is full ripe. This ripens the Beginning of *September*.

22. The *Pavy Royal* (or *Peſche Royale*) is a large round Fruit, of a dark red or black Colour next the Sun, which goes off to a paler red next the Wall; the Fleſh comes from the Stone, where it is very red; the Juice is exquiſitely rich, and equal to, if not exceeding, all other *Peaches* yet known, provided it grows upon a Soil rather dry than moiſt, and is expoſed to a good Aſpect. This ripens the Beginning of *September*.

23. The *Admirable* is a large round Fruit, of a fine red Colour next the Sun, which goes off to a greeniſh yellow next the Wall; the Fleſh is firm, and full of rich ſugar'd Juice; it parts from the Stone, where it is of a deep red Colour. This is a great Bearer, and ripens toward the End of *Auguſt*, or the Beginning of *September*.

24. *La Pavie Rouge de Pompone, ou Monſtreux* (or the *Monſtrous Pavy of Pompone*) is the largeſt *Peach* yet known; it is of a globular Shape, deeply divided into two Parts, of a beautiful red next the Sun, which goes off to a bright yellow next the Wall; the Fleſh is melting, and of a rich vinous Flavour; it ripens the Middle of *September*. This ſhould have a *South Eaſt* Aſpect, and the Shoots ſhould be laid very thin againſt the Walls; for if there are many Fruit upon a Tree, they ſeldom ripen, or are well-flavour'd.

25. The *Catherine Peach* is a fine large Fruit, (eſpecially when not left too thick upon the Trees;) the Skin is covered with a ſoft Down, and is of a dull red Colour next the Sun, which goes off to a whitiſh green next the Wall; the Fleſh is full of a rich vinous Juice, and in a good Seaſon, comes neareſt to the *Old Newington Peach* of any other Sort. This is a great Bearer, but ſhould be planted in a warm Soil, and to a *South-Eaſt* Aſpect. It ripens in the Middle of *September*.

26. The *Rambouillet*, or, as it is commonly called, *Rumbullion*, is a middle-ſized Fruit, rather round than long, deeply divided by a Sulcus or Furrow in the Middle; of a pleaſant red Colour next the Sun, but of a light yellow next the Wall; the Fleſh is of a bright yellow, and parts from the Stone, where it is of a deep red Colour. The Juice is of a rich vinous Flavour. It is a good Bearer, and ripens the Middle of *September*.

27. The *Malacoton* (or *Cotton-Apple*) is a large fair *Peach*; the Skin is covered over with a thick downy Subſtance, from whence it took its Name: it is of a beautiful red Colour next the Sun, but of a light yellow next the Wall; the Fleſh is firm, and full of a rich vinous Juice, and, when duly ripen'd, is an excellent Fruit. This ripens towards the latter End of *September*. It ſhould have a warm Soil, and the Branches muſt be laid very thin againſt the Wall, otherwiſe the Fruit ſeldom comes to any Thing.

28. *La Sanguinolle* (or the *Bloody*) *Peach*, is a middle-ſized Fruit, whoſe Fleſh is of a deep red Colour within, from whence it had its Name; it parts from the Stone; the Outſide next the Sun is of a deep red, but the Side next the Wall is of a greeniſh yellow Colour. This ripens in *October*; ſo that unleſs the *Autumn* proves very favourable, it is not good for any thing.

There are ſeveral other Sorts of *Peaches*, which are very good, in the South of *France*, and other warm Countries, which with us do rarely ripen ſo as to be eatable, for which Reaſon they are not worth cultivating; ſuch are, the *Violette Tardive*, or *Late Violet*; *La Corbeil*; *La Peſche Noix*; the *Double-flower'd*, &c. which ſeldom ripen in *France* until the latter End of *October*, when the Nights are long and froſty, the Seaſon often very wet and cold; ſo that theſe Fruits will be watery, inſipid, and very unwholeſome in this Country.

The *French* diſtinguiſh thoſe we call *Peaches* into two Sorts, *viz.* *Pavies*, and *Peaches*; thoſe are called *Peaches* which quit the Stone; and thoſe whoſe Fleſh cloſely adheres to the Stone are called *Pavies*; theſe are much more eſteemed in *France* than the *Peaches*; tho' in *England* the latter are preferred to the former by many Perſons.

The *French* do alſo diſtinguiſh them into *Male* and *Female*; the *Pavies* they make to be the *Male*, and the *Peaches* the *Female*: But this Diviſion is without Foundation, ſince the Kernels of both Sorts will produce Trees equally; for the Flowers of *Peach-trees* are generally hermaphrodite, and have all the Parts of Generation in them; ſo that there is no Neceſſity of ſuppoſing any of them to be intirely *Male* or *Female*: But it is likely that this Diſtinction is of long ſtanding, before Perſons had a perfect Notion of *Male* and *Female* in Plants, or at leaſt they did not know how to diſtinguiſh them aſunder.

The *Nectarines* (as I have in another Place ſaid) are by the *French* called *Brugnons*, which differ from the other two Sorts, in having a firm hard Fleſh, and the Skins quite ſmooth, without any Down upon them. The Sorts of theſe I have already mentioned under the Article *Nectarines*, to which the Reader may readily turn, therefore I ſhall not repeat them in this Place.

I ſhall now ſet down the good Qualities of *Peaches*, by which any Perſon may judge of their Worth.

A good *Peach* ought to have a firm Fleſh; the Skin ſhould be thin, of a deep or bright red Colour next the Sun, and of a yellowiſh Caſt next the Wall; the Fleſh ſhould be of a yellowiſh Colour, full of Juice, which ſhould be high-flavoured, the Stone ſmall, and the Pulp or Fleſh very thick. When a *Peach* hath all theſe Qualities, it may be eſteemed a valuable Fruit.

All the different Sorts of *Peaches* have been originally obtained from the Stones, which being planted do produce new Varieties, as do the Seeds of all other Fruits; ſo that where Perſons have Garden enough to allow Room for propagating theſe Fruits from Seeds, there is no doubt but many good ſorts may be obtained, which will be better adapted to our Climate than ſuch as are brought from warmer Countries; though, it is true, that there will be many of them good for nothing, as is the Caſe of moſt Fruits and Flowers which are produced from Seeds, amongſt which there may be ſome valuable Kinds, ſuperior to thoſe from whence the Seeds were taken; yet there is always a great Number which are little worth; but if we can obtain only two or three valuable Sorts, it is ſufficient to make Amends for the Trouble of raiſing them; but where Perſons are ſo curious as to plant the Stones of theſe Fruits, great Regard ſhould be had to the Sorts; and if the Fruit were permitted to remain upon the Trees until they dropped off, the Kernels would be fitter for planting, and more likely to grow. The beſt Sorts for ſowing are thoſe whoſe Fleſh is firm, and cleaves to the Stone; and from amongſt theſe you ſhould chuſe ſuch as ripen pretty early, and have a rich vinous Juice; from which Sorts ſome good Fruit may be expected.

Theſe Stones ſhould be planted in *Autumn*, on a Bed of light dry Earth, about three Inches deep, and four Inches aſunder; and in the Winter the Bed ſhould be covered, to protect them from the Froſt, which, if permitted to enter deep into the Ground, will deſtroy them: In the *Spring*, when the Plants come up, they ſhould be carefully cleared from the Weeds, which ſhould alſo be obſerved throughout the *Summer*; and if the *Spring* ſhould prove very dry, if you refreſh them now and then with a little Water, it will greatly promote their Growth: In this Bed they ſhould remain until the following *Spring*, when they ſhould be carefully taken up, ſo as not to break their tender Roots, and tranſplanted into a Nurſery, in Rows three Feet aſunder, and eighteen Inches diſtant Plant from Plant in the Rows, obſerving to lay a little Mulch upon the Surface of the Ground about their Roots, to prevent its drying too faſt: And if the *Spring* ſhould prove very dry, you ſhould give them a little Water once a Week, until they have taken Root; after which they ſhould be conſtantly kept clear from Weeds, and the Ground between the Rows carefully dug every *Spring*, to looſen it, ſo as that the tender Fibres may ſtrike out on every Side.

In this Nurſery they may continue two or three Years; after which they ſhould be tranſplanted, where they are to remain, to produce Fruit.

In removing theſe Trees, you ſhould obſerve to prune their downright Roots (if they have any) pretty ſhort, and to cut off all bruiſed Parts of the Roots, as alſo all the ſmall Fibres, which do generally dry, and when left upon the Roots, after planting again, grow mouldy, and decay; ſo that they are injurious to the new Fibres which are ſhot out from the Roots, and very often prevent the Growth of the Trees: but you ſhould by no means prune their Heads; for the Plants which are produced from Stones, are generally of a more ſpongy Texture, and ſo more liable to decay when cut, than thoſe which are budded upon other Stocks. Beſides, as theſe Trees are deſigned for Standards, (for it is not proper to plant them againſt Walls, until you ſee the Produce of their Fruit, to ſhew which of them deſerves to be cultivated;) ſo they will never require any other pruning, but only to cut out decayed Branches, or ſuch as ſhoot out very irregular from the Sides; for more than this, is generally very injurious to them.

In planting theſe Trees, it will be the better Way to diſpoſe them ſingly in the Quarters of the Kitchen-Garden, where they will thrive and produce Fruit much better, than if they are planted pretty near each other in Rows; and as they are thus ſingly diſpoſed, they will not do much Injury to the Crops which grow under them.

When they have produced Fruit, you will ſoon be a Judge of their Goodneſs: therefore ſuch of them as you diſlike, may be deſtroy'd; but thoſe which are good may be propagated, by inoculating them upon other Stocks, which is the common Method now practiſed to propagate theſe Fruits: therefore I ſhall now proceed to treat of that more particularly; in the doing of which, I ſhall ſet down the Method now commonly practiſed by the Nurſery Gardeners; and then propoſe ſome few Things of my own, as an Improvement thereon, for ſuch Perſons who are very curious to have good Fruit. But firſt,

You ſhould be provided with Stocks of the *Muſcle* and *White-Pear-Plums*, which are generally eſteem'd the two beſt Sorts of *Plums* for Stocks, to inoculate *Peaches* and *Nectarines* upon; as alſo ſome *Almond* and *Apricock* Stocks, for ſome tender Sorts of *Peaches*, which will not grow upon *Plum* Stocks: theſe ſhould be all produced from the Stone, (as hath been already directed in the Article of a *Nurſery*) and not from Suckers, for the Reaſons there laid down.

When theſe Stocks have grown in the Nurſery two Years, they will be ſtrong enough to bud, the Seaſon for which is commonly about *Midſummer*; when you ſhould make choice of ſome good Cuttings of the Sorts of Fruit you intend to propagate, always obſerving to take them from healthy Trees, and ſuch as do generally produce a good Quantity of well-taſted Fruit; for it is very certain, that any Sort of Fruit may be ſo far degenerated, where this Caſe is wanting, as not to be like the ſame Kind. Beſides, whenever a Tree is unhealthy, the Buds taken from that Tree will always retain the Diſtemper, in a greater or leſs Degree, according as it hath imbibed a greater or leſs Quantity of the diſtemper'd Juice. Thus, for Inſtance, where a *Peach* or *Nectarin* Tree hath been greatly blighted, ſo as that the Shoots have grown buſled, and the Leaves curled up to a great degree, that Diſtemper is ſeldom recover'd again by the greateſt Art, or at leaſt not under ſeveral Years Management; for let the Seaſons prove ever ſo favourable, yet theſe Trees will continually ſhew the ſame Diſtemper: which many Perſons are ſo weak as to ſuppoſe a freſh Blight: whereas in reality it is no other but the Remains of the former Sickneſs, which are ſpread and intermix'd with all the Juices of the Tree; ſo that whatever Buds are taken from ſuch Trees, will always retain a Part of the Diſtemper.

The Cuttings with which you are thus to be provided, ſhould always be taken from the Trees either in a Morning or Evening, or elſe in a cloudy Day; for if they are cut off when the Sun is very hot, the Shoots will perſpire ſo freely, as to leave the Buds deſtitute of Moiſture, which is often the Cauſe of their miſcarrying; and the ſooner theſe are uſed when cut from the Trees, the better they will take. The Manner of this Operation being fully explain'd under the Article of *Inoculation*, I ſhall not repeat it in this Place. The Management of theſe Trees during their remaining Time in the *Nurſery*, is likewiſe fully ſet down under that Article. I ſhall therefore proceed to the Planting of theſe Trees, either againſt Walls, Eſpaliers, or for Standards. But as the future Succeſs of theſe Trees doth in a great meaſure depend upon the Soil in which they are planted; ſo I ſhall briefly ſet down the Method of Preparing the Earth for the Borders where they are deſigned to grow.

The beſt Earth for *Peach-Trees*, is ſuch as is taken from a Paſture Ground, that is neither too ſtiff and moiſt, nor over-dry, but of a middling Nature: this ſhould be dug from th Surface of the Ground about ten Inches deep, taking th Turf with it; and ſhould be laid in Heaps eight or te Months before it be uſed, during which Time it ſhould b often turned, to rot the Turf, and break the Clods, where by it will be render'd very light, and eaſy to work; and a bout the Beginning of *September* you ſhould carry it into th Garden, and make the Borders, which muſt be raiſed i Height proportionable to the Moiſture of the Garden; f if the Ground be very wet, it will be adviſeable to lay ſom Rubbiſh in the Bottom of the Border, to drain off the Mo ſture, and to prevent the Roots of the Trees from runni downwards; then raiſe the Border of Earth at leaſt Foot above the Level of the Ground, ſo that the Roots of t Trees may always remain dry: but if the Ground be pret dr dry, the Borders ſhould not be raiſed above four or five Inches higher than the Surface, which will be ſufficient to allow for their ſinking.

As to the Breadth of theſe Borders, that can't be too great; but they ſhould never be leſs than ſix Feet broad where Fruit-Trees are planted; for when the Borders are made very narrow, the Roots of the Trees will be ſo confined in four or five Years time, that they will ſeldom thrive well after. The Depth of theſe Borders ſhould not be greater than two Feet; for where they are prepared to a great Depth, it only intices the Roots of the Trees downward, which may be the Cauſe of their future Barrenneſs; for their Roots being got down below the Influences of the Sun and Showers, do imbibe a great Quantity of crude Juices; which only add to the luxuriant Growth of the Trees, and deſtroy their Fruitfulneſs: beſides whatever Fruit are produced from ſuch Trees, are not near ſo well-taſted, as are thoſe which grow upon thoſe Trees whoſe Roots lie near the Surface, and enjoy the kindly Benefit of the Sun's Heat, to correct and digeſt whatever Crudities there may be in the Earth.

Your Borders being thus prepared, ſhould lie about three Weeks or a Month, to ſettle, by which time the Seaſon for Planting will be come, which ſhould be perform'd as ſoon as the Leaves begin to decay, that the Trees may take Root before the Froſt comes on to prevent them: then you ſhould carefully take up the Trees out of the Nurſery, ſo as not to break or bruiſe their Roots; and with a ſharp Knife you muſt prune the extreme Parts of them, and cut off ſmooth any broken or bruiſed Roots; as alſo all the ſmall Fibres ſhould be taken off, for the Reaſons before given.

And having thus prepared your Trees, you ſhould meaſure out their Diſtance, which ought never to be leſs than fourteen Feet; but where the Ground is very good, they ſhould be planted ſixteen Feet aſunder. This, I doubt not, will be thought too great a Diſtance by many Perſons, eſpecially ſince it is contrary to the general Practice at this Time: but I am ſatisfied, whoever ſhall try the Experiment, will find it no more than is ſufficient for theſe Trees, where they are rightly managed; for if they do take kindly to the Soil, their Branches may be ſo train'd, as to furniſh all the lower Part of the Wall in a few Years: which is what ſhould be principally regarded, and not, as is too often the Practice, run up the Shoots in Height, and leave all the lower Part of the Tree deſtitute of bearing Wood; ſo that, in a few Years, there will not be any Fruit but upon the upper Part of the Trees: which alſo muſt be the Caſe where they are planted too cloſe; becauſe there being no Room to extend the Branches on either Side, they are obliged to lead them upright, which produces the before-mention'd ill Effect.

And here I can't help taking notice of another very great Error in planting Wall-Fruit; which is, the placing Standard or Half-Standard Trees between the others, to cover the upper Part of the Wall, and to produce Fruit, until the Trees underneath are grown up ſufficient to furniſh the Walls, when the Standards are to be taken away: this is done, without conſidering that the greater Number of Trees are planted in a ſmall Compaſs, the leſs Nouriſhment they can receive, and ſo, conſequently, muſt be the weaker; for the ſame Space of Ground can't nouriſh twenty Trees equally as well as it could ten: ſo that whatever Strength the Standard-Trees may have, the Dwarfs will be proportionably weaker: and it is a common Obſervation, that moſt Trees extend their Roots as far under Ground, as their Branches ſpread above Ground; ſo that there ſhould always be the ſame Allowance given to the Wall-Trees, if we would have them ſtrong and vigorous; therefore the building very high Walls for Fruit is to no Purpoſe; for a ten or twelve Foot Wall will be ſufficient for moſt Sorts of Fruit.

But to return to Planting: After you have mark'd out the Places where each Tree is to ſtand, you muſt with your Spade make a Hole wide enough to receive the Roots of the Tree; then you ſhould place it down, obſerving to turn the Bud outwards, that the wounded Part of the Stock may be hid, and let the Stem of the Tree be placed about four or five Inches from the Wall, with its Head inclining thereto; then fill in the Earth with your Hands, obſerving to break the Clods, that the Earth may fall in between the Roots, ſo as no void Spaces may be left about them. You ſhould alſo gently ſhake the Tree with your Hands, to ſettle the Earth down the better; then with your Foot gently preſs down the Earth about the Stem; but do not tread it down too hard, which is many times a very great Fault; for when the Ground is inclinable to bind, the treading of it cloſe doth often render the Ground ſo hard, as that the tender Fibres of the Roots can't ſtrike into it, whereby the Trees remain at a Stand for ſome time; and if the Earth be not looſen'd in Time, it frequently dies: ſo that whenever you obſerve the Earth of your Borders to be bound, either by great Rains, or from any other Cauſe, you ſhould dig and looſen it again, obſerving always to do it in dry Weather, if in *Winter* or *Spring*; but in *Summer* it ſhould be done in a moiſt Seaſon.

After you have thus planted your Trees, you ſhould faſten their Heads to the Wall, to prevent their being ſhaken by the Wind, which would diſturb their Roots, and break off the tender Fibres ſoon after they were produced, to the no ſmall Prejudice of the Trees: You ſhould alſo lay ſome Mulch upon the Surface of the Ground about their Roots, to prevent the Froſt from penetrating the Ground, which would injure, if not deſtroy the ſmall Fibres.

Theſe Things being duly obſerved, they will require no farther Care till the *February* following; towards the latter End of which Month, or the Beginning of *March*, according as the Seaſon is earlier or later, you muſt cut off the Heads of the new-planted Trees, leaving only four or five Eyes above the Bud; in doing of which, you muſt be very careful not to diſturb their Roots; to prevent which, you ſhould place your Foot down cloſe to the Stem of the Tree, and take faſt hold of that Part of the Stock below the Bud with one Hand, to hold it ſteady, while with the other Hand you gently ſlope off the Head of the Tree with a ſharp Knife at the intended Place, which ſhould always be juſt above an Eye: this ſhould always be done in dry Weather; for if there ſhould be much Rain ſoon after it is done, the Wet will enter the wounded Part, and damage the Tree: nor ſhould it be done in froſty Weather, for the ſame Reaſon; for that would enter the wounded Part, and prevent its healing over. After you have headed the Trees, you ſhould gently looſen the Earth of the Borders, to admit the Fibres of the Roots: but you muſt be very careful, in doing of this not to cut or bruiſe their new Roots, which would alſo damage them: and if the Mulch which was laid about their Roots in *Autumn* be rotted, you may dig it into the Border at ſome Diſtance from the Roots of the Trees; and when the dry Weather comes on, you ſhould pare off ſome Turf from a Paſture Ground, which ſhould be laid upon the Surface of the Border about the Roots of the Trees, turning the Graſs downwards, which will preſerve a gentle Moiſture in the Earth better than any other ſort of Mulch; and this will not harbour Inſects, as do moſt ſorts of Dung and Litter, to the no ſmall Detriment of the Trees.

In watering of theſe Trees, you ſhould obſerve to do it with a Noſſel upon the Watering-Pot, ſo as to let it out in Drops; for when it is haſtily pour'd down, it cauſes the Ground to bind; and if you water over the Head of the Tree, it will be of great Service to it. Your Waterings ſhould not be repeated too often, nor ſhould it be given them in great Quantity, both which are very injurious to new-planted Trees.

In the Middle of *May*, when theſe Trees will have ſeveral Shoots ſix or eight Inches in Length, you ſhould nail them to the Wall, obſerving to train them horizontally, rubbing off all fore-right Shoots, or ſuch as are weak, whereby thoſe which are preſerved will be much ſtronger: but if there are not more than two Shoots produced, and thoſe very ſtrong, you ſhould at the ſame time nip off their Tops, which will cauſe each of them to puſh out two or more Shoots, whereby the Wall will be better ſupplied with Branches: you muſt alſo continue to refreſh them with Water in dry Weather, during the whole Seaſon, otherwiſe they will be apt to ſuffer; for their Roots having but little Hold of the Ground the firſt year after tranſplanting, if the Seaſon ſhould prove very dry, it will greatly retard their Growth, if due Care be not taken to water them.

In the Beginning of *October*, when you obſerve the Trees have done ſhooting, you ſhould prune them; in doing of which, you muſt ſhorten the Branches in proportion to the Strength of the Tree; which, if ſtrong, may be left eight Inches long; but if weak, ſhould be ſhorten'd to four or five: then you ſhould train them horizontally to the Wall, (as was before directed;) ſo that the Middle of the Trees may be void of Branches; for that Part of the Tree will be eaſily furniſh'd with Wood afterwards; whereas if the Shoots are train'd perpendicularly to the Wall, thoſe which are the ſtrongeſt will draw the greateſt Share of the Sap from the Roots, and mount upwards; ſo that the Side-Branches will be deprived of their Nouriſhment, and grow weaker, until they, many times, decay; and this is the Reaſon that we ſee ſo many *Peach-Trees* with one upright Stem in the Middle, and the two Sides wholly unfurniſh'd with Branches, whereby the Middle of each Tree cannot produce any Fruit, that being fill'd with large Wood, which never produces any Bearing Shoots: nor can the two Sides of the Trees be regularly fill'd with fruitful Branches, when this Defect happens to them; therefore this Method ſhould be carefully obſerved in the training up young Trees; for when they are permitted to run into Diſorder at firſt, it will be impoſſible to reduce them into a regular healthful State afterwards, the Wood of theſe Trees being too ſoft and pithy to admit of being cut down again, (as may be practiſed on many other hardy Fruit-trees, which will ſhoot out vigorouſly again;) whereas theſe will gum at the Places where they are wounded, and in a few Years intirely decay.

The Summer following, when the Trees begin to ſhoot, you ſhould carefully look over them, to rub off all fore-right Buds, or ſuch as are ill placed, and train thoſe which are deſign'd to remain horizontally to the Wall, in their due Order as they are produced; for this is the principal Seaſon when you can beſt order the Trees as you would have them; whereas if they are neglected until *Midſummer*, as is the common Practice, a great part of the Nouriſhment will be exhauſted by foreright Shoots, and other uſeleſs Branches, which muſt afterwards be cut off; and hereby the remaining Shoots will be render'd very weak, and perhaps ſome Part of the Wall be intirely unfurniſh'd with Branches; which might have been eaſily ſupplied in the Beginning of *May*, by ſtopping ſome of the ſtronger Shoots in ſuch Parts of the Tree where there is a Neceſſity for more Branches, which would cauſe each of them to ſhoot out two or more Side-Branches below the Ends of the Shoots, which may be guided into the vacant Parts of the Tree, as they are produced, ſo as that every Part may be regularly furniſhed with proper Wood, which is the greateſt Beauty and Excellency of Wall-Trees: but you ſhould always forbear ſtopping the Shoots in *Summer*, where there is not a Neceſſity for Branches to fill the Wall; for there cannot be a greater Fault committed, than that of multiplying the Number of Shoots, ſo as to cauſe a Confuſion, whereby the Branches will be too weak to produce good Fruit: beſides, when they are too cloſely laid in upon the Wall, the Air is excluded from the Shoots by the great number of Leaves, ſo that they are never duly ripen'd, and, conſequently, what Fruit is produced thereon can't be ſo well-taſted as thoſe which are produced upon ſuch Trees where the Shoots receive all the Advantages of Sun and Air to maturate them.

Thus having ſet down the Method of Training up young Trees, I ſhall now proceed to their Pruning, and future Management; which being the ſame as with full-grown Trees, will ſerve for general Directions how to manage theſe Sorts of Fruit.

In the Pruning of *Peach* and *Nectarine*-Trees, (which require the ſame Culture) the two following Rules ſhould be ſtrictly obſerved; *viz.* *1ſt*, That every part of the Tree be equally furniſh'd with Bearing-Wood; and, *2dly*, That the Branches are not laid in too cloſe to each other, for the Reaſons before laid down, (with ſome others, which will be hereafter inſerted.) As to the firſt, it muſt be obſerv'd, that all theſe Trees do produce their Fruit upon the young Wood, either of the preceding Year, or at moſt the two Years Shoots, after which Age they do not bear: therefore the Branches ſhould be pruned ſo as to cauſe them to produce new Shoots annually in every Part of the Tree; which cannot be done in the ordinary Method of Pruning, where Perſons neglect their Trees at the Seaſon when they are moſt capable of Management, which is in *May*, at which Time the luxuriant Growth of Branches may be check'd by pinching, and new Shoots produced where they are wanting, by ſtopping the neighbouring branches; which Shoots being produced at that Seaſon, will have Time enough to ripen and gain Strength before the *Autumn* comes on; whereas all thoſe Shoots which are produced after the Beginning of *June*, will be crude and pithy; and tho' they may ſometimes produce a few Bloſſoms, yet thoſe do rarely bring Fruit; nor are the future Branches good which are produced from ſuch Wood, the Veſſels being too large to ſtrain the Juices, ſo that they eaſily admit of great Quantities of crude Nouriſhment to paſs thro' them. Therefore thoſe Perſons who only regard their Wall-Trees at two different Seaſons, *viz.* the *Winter* and *Midſummer* Pruning, can't poſſibly have them in good Order; for when all the Branches which were produced in the *Spring* are permitted to remain until the Middle or latter End of *June*, (as is the common Practice) ſome of the moſt vigorous will draw the greateſt Part of the Nouriſhment from the weaker Branches, which, when the ſtrong ones are taken off, will be too weak to produce fair Fruit; and hereby the Strength of the Trees is exhauſted, to nouriſh the uſeleſs Branches, which are annually cut off again: and thus are too many Trees managed, and at the ſame time Complaints made of their Luxuriancy; becauſe two or three Shoots, by drawing in the greateſt Share of the Nouriſhment, grow very ſtrong and woody: (whereas if the Nouriſhment had been equally diſtributed to a regular Quantity of Branches, there would be no Sign of their too great Strength,) untill by often cutting off theſe vigorous Branches, the Trees are either intirely deſtroy'd, or at leaſt render'd ſo weak as not to be able to produce Fruit: for altho' by thus weakening the Branches it is often the Means to produce a good number of Bloſſoms, (as may many times be obſerved alſo upon Autumnal Shoots,) yet the utmoſt of their Strength is ſpent in expanding the Flowers, ſo that they rarely produce Fruit, and very often the greateſt Part of the Branches die ſoon after, which is ſuppoſed to be occaſion'd by a Blight, (as I have elſewhere ſaid) when in reality it is nothing leſs than the Fault of thoſe who have the Management of the Trees. It is therefore of the greateſt Conſequence to Wall-Trees, eſpecially of theſe Sorts, to go over them two or three times in the Month of *May*, to rub off all irregular Shoots, and to train in the Branches that are left in due Order to the Wall, that each Shoot may have an equal Advantage of Sun and Air, both of which are abſolutely neceſſary to ripen and prepare the Wood for the next Year's Bearing.

And by duly obſerving the Trees at this Seaſon, there will not be Occaſion for ſo much Cutting, as is often practiſed on *Peach-Trees*, to their great Injury; for their Wood-Branches are generally ſoft, tender, and pithy, which, when greatly wounded, are not heal'd over again ſo ſoon as many other Sorts of Trees; and the Wet inſinuating into the wounded Parts, doth often cauſe the Branches to canker and die; which may be intirely avoided, by the gentle, eaſy Method of pinching and rubbing off the Buds in the *Spring* Seaſon, which never makes any Wounds on the Tree; and hereby a vaſt deal of Labour is ſaved; for one Perſon, who is ready at this Buſineſs, will go over a great Quantity of Walling in a Day; whereas if the Trees are permitted to grow rude all the *Spring*, they will require ſix times the Labour to reduce them into Order. Beſides, it is a great Diſadvantage to the Fruit, in permitting the Branches of the Trees to extend from the Wall, and ſhade them; and when they have grown under the Shelter of theſe Branches and Leaves all the *Spring*, until *Midſummer*, then by pruning off ſome of theſe Shoots, and nailing the others cloſe to the Wall, the Fruits are ſuddenly expoſed to the Sun and Air, whereby they receive a very great Check, and are not only retarded in their Growth, but often render'd ill-taſted, and have tough Skins.

The Diſtance which the Branches of theſe Trees ſhould be allow'd againſt the Wall, muſt be proportion'd to the Size of the Fruit, or the Length of the Leaves: for if we obſerve how the Branches of Trees are naturally diſpoſed to grow, we ſhall always find them placed at a greater or leſs Diſtance, as their Leaves are larger or ſmaller, (as I have already obſerved under the Articles of *Leaves*:) and there is no ſurer Guide to a curious Artiſt than Nature, from whence a Gardener ſhould always be directed in every Part of his Profeſſion; ſince his Buſineſs is to aid and aſſiſt Nature, where ſhe is not capable of bringing her Productions to Maturity, or where there is Room to make conſiderable Improvements by Art; which cannot be any otherwiſe effected, than by gently aſſiſting her in her own Way.

But to return to Pruning of theſe Trees: The Branches being carefully train'd in, as before directed in the *Spring* and *Summer* Seaſons, we come now to treat of the *Winter* Pruning, which is commonly perform'd in *February* or *March*: but the beſt Seaſon for this Work is about *Michaelmas*, when their Leaves begin to fall, which will be early enough for their Wounds to heal, before the Froſt comes on, ſo that there will be no danger of their being hur thereby: and the Branches of the Trees being proportion' to the Strength of the Roots at that Seaſon, all the aſcending Sap in the *Spring* will be employed to nouriſh only thoſ uſeful Parts of the Branches which are left; whereas if they are left unpruned till *February*, the Sap in the Branches being then in Motion, as may be obſerv'd by the ſwelling o the Buds, the greateſt Part of it will be drawn up to th extreme Parts of the Branches, to nouriſh ſuch Bloſſoms muſt be afterwards cut off: and this may be eaſily known by obſerving the ſtrongeſt Shoots at that Seaſon, when yo will find the extreme Buds to ſwell faſter than moſt of th lower ones; for there being no Leaves then upon th Branches, to detain the Sap to nouriſh the lower Buds, th upper ones will always draw from thoſe below.

But it is a conſtant Practice amongſt Gardeners, founde upon long Experience, to prune weak Trees early in th *Winter*, and luxuriant Trees late in the *Spring* in order check their Luxuriancy. Now it is evident, that this Chec does not proceed from any conſiderable Loſs of Sap at th

Woun

Wounds of the pruned Tree, (excepting a few of the bleeding Trees, when cut at that Seaſon,) but muſt ariſe from ſome other Cauſe; for by ſeveral Experiments made by the Rev. Dr. *Hales*, in fixing Mercurial Gages to the Stems of freſh-cut Trees, he found thoſe Wounds were conſtantly in an imbibing State, except the Vine in the bleeding Seaſon.

When a weak Tree is pruned early in the Beginning of *Winter*, the Orifices of the Sap-veſſels are cloſed up long before the *Spring*; and conſequently, when in the *Spring* and *Summer*, the warm Weather advancing, the attracting Force of the perſpiring Leaves is not then weaken'd by many Inlets from freſh Wounds, but is wholly exerted in drawing Sap from the Root: whereas, on the other hand, when a luxuriant Tree is pruned late in the *Spring*, the Force of its Leaves to attract Sap from the Root will be much ſpent and loſt, at the ſeveral freſh-cut Inlets.

Beſides, if it were no Advantage to the Trees to prune them at this Seaſon, (which I think, no one will have Reaſon to doubt, after making the Trial,) but that it only ſucceeds as well as the *Spring* Pruning, yet there is a great Advantage in doing of it at *Michaelmas*; for that being a much more Leiſure Seaſon with Gardeners than the *Spring*, they will have more Time to perform it carefully; and then they will not have too many Things come together, which may require to be immediately executed: for the *Spring* being the principal Seaſon for Cropping their Kitchen-Gardens, and attending their Hot-beds, if they are diſingaged from the Buſineſs of Pruning at that Time, it will be of great Advantage, eſpecially where there is a great Quantity of Walling. And here is alſo another Benefit in Pruning at this Seaſon, which is, the having the Borders at liberty to dig and make clean before the *Spring*, ſo that the Garden may not appear in Litter at that Seaſon.

Having ſaid thus much concerning the Time of Pruning, I ſhall now proceed to give ſome general Directions how it is to be perform'd on *Peach* and *Nectarine* Trees, which require a very different Management from moſt other Sorts of Fruits.

In Pruning of theſe Trees, you ſhould always obſerve to cut them behind a Wood-bud, (which may be eaſily diſtinguiſh'd from the Bloſſom-buds, that are ſhorter, rounder, and more turgid than the Wood-buds;) for if the Shoot have not a leading Bud where it is cut, it is very apt to die down to the next leading Bud; ſo that what Fruit may be produced above that, will come to nothing, there being always a Neceſſity of a leading Bud to attract the Nouriſhment; for it is not ſufficient that they have a Leaf-bud, as ſome have imagined, ſince that will attract but a ſmall Quantity of Nouriſhment; the great Uſe of the Leaves being to perſpire away ſuch crude Juices as are unfit to enter the Fruit: the Length you ſhould leave theſe Branches, ſhould be proportion'd to the Strength of the Tree, which, in a healthy ſtrong Tree may be left ten Inches or more; but in a weak one, they ſhould not be more than ſix Inches; however, in this you muſt be guided by the Poſition of a leading Bud; for it is better to leave a Shoot three or four Inches longer, or to cut it two or three Inches ſhorter, than we would chuſe to do, provided there be one of theſe Buds, it being abſolutely neceſſary, for the future Welfare of the Tree: you ſhould alſo cut out intirely all weak Shoots, tho' they may have many Bloſſom-buds upon them; for theſe have not Strength enough to nouriſh the Fruit, ſo as to give it a kindly Flavour; but they will weaken the other Parts of the Tree.

In nailing the Shoots to the Wall, you muſt be careful to place them at as equal Diſtances as poſſible, that their Leaves, when come out, may have Room to grow, without ſhading the Branches too much; and you ſhould never nail them upright, if it can be prevented; for when they are thus train'd, they are very ſubject to ſhoot from the upper-moſt Eyes, and the lower Part of the Shoots will thereby become naked.

There is not any thing in the Buſineſs of Gardening, which has more exerciſed the Thoughts of the Curious, than how to preſerve their tender Sorts of Fruit from being blighted in the *Spring* of the Year; and yet there has been little wrote upon this Subject, which is worth Notice: Some have propoſed Mattreſſes of Straw or Reeds to be placed before the Fruit-Trees againſt Walls, to prevent their being blaſted: Others have directed the fixing horizontal Shelters in their Walls, to prevent the perpendicular Dew or Rain from falling upon the Bloſſoms of the Fruit-Trees, which they ſuppoſed to be the chief Cauſe of their Blighting: but both theſe Contrivances have been far from anſwering the Expectations of thoſe Perſons who have put them in Practice, (as I have elſewhere ſhewn;) therefore it may not be improper to repeat ſome Things in this Place, which I have before mentioned, in relation to this Matter. And,

1ſt, I have already ſaid, that the Blights, which are ſo often complained of, do not proceed from any external Cauſe or Inclemency in the Seaſon, ſo often as from a Diſtemper or Weakneſs in the Trees; for if we obſerve the Trees at that Seaſon, where they are the moſt ſubject to what is call'd a Blight, we ſhall find the Branches very ſmall, weak, and not half ripened, as alſo trained in very cloſe to each other; theſe Branches are, for the moſt part, full of Bloſſom-buds (which is chiefly occaſioned by their want of Strength.) Theſe Buds do indeed open, and to Perſons not ſkilled in Fruit-trees, ſhew a great Proſpect of a plentiful Crop of Fruit; whereas the whole Strength of the Branches is ſpent in nouriſhing the Flowers, and being unable to do any more, the Bloſſoms fall off, and the ſmall Efforts of the Leaf-buds are checked, ſo that, many times, the greateſt Part of the Branches die away; and this is called a great Blight: Whereas at the ſame time it may be often obſerv'd, that ſome Trees of a different Sort, nay, even ſome of the ſame Sort, which were ſtronger, tho' placed in the ſame Soil, expoſed to the ſame Aſpect, and ſubject to the ſame Inclemency of Air, have eſcaped very well, when the weak Trees have appeared to be almoſt dead: which is a plain Indication that it proceeds from ſome Cauſe within the Tree, and not from any external Blight. All this will therefore be remedied, by obſerving the foregoing Directions in the Pruning and Management of the Trees, ſo as never to overburden them with Branches, nor to ſuffer any Part of the Trees to exhauſt the whole Nouriſhment from the Root, ſo as to cauſe the other Parts to be very weak; but to diſtribute the Nouriſhment equally to every Shoot, ſo that there may be none too vigorous, at the ſame Time that others are too weak; and by continually rubbing off uſeleſs or fore-right Shoots, as they are produced, the Strength of the Trees will not be ſpent, to nouriſh ſuch Branches as muſt be afterwards cut out, which is too often ſeen in the Management of theſe Trees. And,

2dly, It ſometimes happens that the Roots of theſe Trees are buried too deep in the Ground, which, in a cold or moiſt Soil, is one of the greateſt Diſadvantages that can attend theſe tender Fruits; for the Sap which is contained in the Branches, being by the Warmth of the Sun put ſtrongly into Motion early in the *Spring*, is exhauſted in nouriſhing the Bloſſoms, and a Part of it is perſpired thro' the Wood-branches, ſo that its Strength is loſt before the Warmth can reach to their Roots, to put them into an equal Motion in ſearch of freſh Nouriſhment, to ſupply the Expence of the Branches; for want of which the Bloſſoms fall off and decay, and the Shoots ſeem to be at a ſtand, until the farther Advance of the Warmth penetrates to the Roots, and ſets them in Motion; when ſuddenly after the Trees, which before looked weak and decaying, do make prodigious Progreſs in their Shoots, and before the *Summer* is ſpent, are furniſh'd with much ſtronger Branches than thoſe Trees which have the full Advantage of Sun and Showers, and that are more fruitful and healthy; which muſt certainly be owing to the former Obſervation, as alſo to their drawing in a great Quantity of crude Moiſture, which, tho' productive of Wood, is yet unkindly for Fruit. If, therefore, this be the Caſe, there is no Way of helping this but by raiſing up the Trees, if they are young; or, if they are too old to remove, it is the better Way to root them out, and make new Borders of freſh Earth, and plant down young Trees; for it is a great Vexation to be at the Trouble and Expence of pruning and managing theſe Trees, without having the Pleaſure of reaping any Advantage from them. Which will always be the Caſe, where the Trees are thus injudiciouſly planted. Or,

3dly, This may proceed from the Trees wanting Nouriſhment, which is many times the Caſe where they are planted in a hard gravelly Soil, in which it is the common Practice to dig Borders three or four Feet wide, and three Feet deep into the Rock of Gravel, which is filled with good freſh Earth, into which the Trees are planted, where they will thrive pretty well for two Years, until their Roots reach the Gravel, where they are confined, as if planted in a Pot, and for want of proper Nouriſhment the Branches do continually decay every Year. This cannot be helped, where the Trees have been growing ſome Years, without taking them intirely up, or by digging away the Gravel from their Roots and adding a large Quantity of freſh Earth, that may afford them a Supply of Nouriſhment. But where a Perſon intends to plant Fruit-trees upon ſuch a Soil, I would adviſe him never to dig into the Gravel, but, on the contrary, to raiſe the Borders at leaſt two Feet above it, with good freſh Earth, which, if made of a conſiderable Width, ſo that their Roots may have Room to extend themſelves upon the

Gravel, they will enjoy the kindly Influences of the Sun and Showers, and produce delicate well-flavoured Fruit in plenty.

But if the Unfruitfulneſs of the Trees do not proceed from any of the before-mentioned Cauſes, and is the Effect of unkindly Seaſons, then the beſt Method yet known, is in froſty dry Weather, when little Dew falls, to ſprinkle the Branches of the Trees gently with Water in the bloſſoming Seaſon; and while the young-ſet Fruit is tender, (which ſhould always be done before Noon, that the Moiſture may evaporate before the Night comes on) and if in the Night you carefully cover the Trees with Mats, Canvas, or ſome ſuch light Covering, it will be of great Service to them: However, where the Trees are ſtrong and vigorous, they are not ſo liable to ſuffer by a ſmall Inclemency as are thoſe which are weak; ſo that there will be few Seaſons in which there may not be Hopes of a moderate Quantity from them, tho' there ſhould be no Covering uſed.

When your Fruit is ſet, and grown to the Bigneſs of a Small-nut, you ſhould go over the Trees and thin them, leaving them at leaſt five or ſix Inches aſunder; for when they are permitted to remain in Bunches, as they are often produced, the Nouriſhment which ſhould be employ'd wholly to the Fruits deſigned to ſtand, will be equally ſpent amongſt the whole Number, a great Part of which muſt be afterwards pulled off; ſo that the ſooner this is done, the better it will be for the remaining Fruit: And if it ſhould ſometimes happen that a Part of thoſe left, by any Accident ſhould be deſtroyed, yet the remaining ones will be much the larger and better taſted for it, and the Trees will gain more Strength; for a moderate Quantity of Fruit is always preferable to a great Crop; the Fruit, when but few, will be much larger, better taſted, and the Trees in a Condition to bear well the ſucceeding Years; whereas when they are overcharged with Fruit, it is always ſmall, ill-taſted, and the Trees are generally ſo much weakened thereby, as not to be in a Condition for bearing well for three or four Years after. So that, upon the whole, it is much better to have a leſſer Number of Fruit than is commonly eſteemed a Crop, than to have too many, ſince the Fruit and alſo the Trees are benefited thereby.

The farther Management of *Peach-trees* in *Summer* I have already mentioned, and ſhall only add a Word or two more upon that Head in this Place.

1ſt, That the Shoots being regularly trained to the Wall as they are produced, the Fruit will always be equally expoſed to the Sun and Air, by which it will be kept in a conſtant and equal State of Growing; whereas when they are over-ſhadowed by luxuriant Branches for ſome time, and afterwards expoſed to the Sun, by cutting off thoſe Branches, their Skins will grow tough, and the Fruit be greatly retarded in its Growth.

2dly, By rubbing off and diſplacing irregular Shoots as they are produced, there will be no need to uſe a Knife to theſe Trees in *Summer*, which is what they are often greatly injured by; for when there are large Wounds made on theſe Trees, eſpecially in *Summer*, it weakens them very much. Beſides (as I before ſaid) by doing this early, the Sap of the Trees is not employed to nouriſh uſeleſs Branches.

3dly, I would adviſe, never to ſhorten any of the Branches in *Summer*, unleſs it be to procure ſome ſide Shoots to fill up a Vacancy of the Wall; and this ſhould never be done after *May*, becauſe the Shoots produced after that Time are never duly ripened, and ſo are no better than Autumnal Branches.

When theſe Rules are duly executed, there will be no Occaſion to pull off the Leaves of the Trees, to admit the Sun to the Fruit, which is too often practiſed; for if we conſider, that the Leaves are abſolutely neceſſary to cheriſh the Bloſſom-buds, which are always formed at the Foot-ſtalks of the Leaves, ſo by pulling them off before they have performed the Office aſſigned them by Nature, is doing great Injury to the Trees; therefore I caution every one againſt that Practice.

PERSICARIA, [ſo called, becauſe its Leaves reſemble a *Peach*: It is alſo called *Hydro-piper*, of ὕδωρ, *Water*, and ϖέπερι, *Pepper*, becauſe it is an Aquatick Plant, and has the Taſte of Pepper] Arſmart.

The *Characters* are;

It is a Plant with an apetalous Flower, having ſeveral Stamina (or Chives) which ariſe from the multifid Calyx: The Pointal afterwards becomes an oval-pointed ſmooth Seed, incloſed in the Capſule, which was before the Flower-cup: To which may be added, it hath jointed Stalks, and the Flowers are produced in Spikes.

The *Species* are;

1. PERSICARIA *mitis maculoſa. C. B. P.* Dead *or* Spotted Arſmart.

2. PERSICARIA *vulgaris acris, ſeu Hydro-piper. J. B.* Water-pepper, Lake-weed, *or* Arſmart.

3. PERSICARIA *major, lapathi foliis, calyce floris purpureo. Tourn.* Great Arſmart, with Dock-leaves, and a purple Flower-cup.

4. PERSICARIA *Orientalis, Nicotianæ folio, calyce florum purpureo. T. Cor.* Eaſtern Arſmart, with a Tobacco-leaf, and a purple Flower-cup.

There are ſeveral other Species of this Plant, which grow wild upon moiſt Soils and Dunghills in divers Parts of *England*; but as they are rarely cultivated in Gardens, and being Plants of no Uſe at preſent, ſo I omit enumerating of them in this Place.

The two firſt ſorts here mentioned are ſometimes uſed in Medicine; the latter of which is a very ſharp acrid Plant, from whence it had its Name of *Water-pepper* and *Arſmart*: This is a perennial Plant, which grows in great Plenty on the Sides of Ditches, and in moiſt Places, almoſt in every Part of *England*, and is a very bad Weed, if once it gets Poſſeſſion in a Garden; for the Roots extend themſelves greatly under Ground, and ariſe from every Joint (as doth *Couch-graſs)* ſo that it is with great Difficulty extirpated.

The firſt is an annual Plant, that propagates itſelf in great plenty from Seeds, which falling upon the Ground, riſe the ſucceeding *Spring*, and ſpread over the Ground, wherever they are permitted to grow; ſo that they ſhould not be ſuffered to remain in Gardens: Theſe are both gathered in the Fields in *Autumn* for medicinal Uſe, when they are in Perfection.

The third Sort is cultivated in ſome curious Gardens for Variety, it making a handſome Appearance during the Seaſon of its Flowering: This may be propagated by ſowing the Seeds upon a Bed of rich moiſt Earth in *Autumn*, ſoon after they are ripe, and the Plants will come up the *Spring* following, when they may be tranſplanted into the Borders where they are to remain: This is alſo an annual Plant, which requires to be ſown every Year, or the Seeds permitted to shed, which will grow better than thoſe which are ſown by Art.

The fourth Sort was brought from the Eaſtern Country by Monſ. *Tournefort*, to the *Royal Garden* at *Paris*, from whence it hath been ſince communicated to ſeveral Parts of *Europe*. This Plant (though but an Annual) doth grow to be ten or twelve Feet high, and divides into ſeveral Branches, each of which produces a beautiful Spike of purple Flowers at their Extremities in the *Autumn*; which, together with its large green Leaves, and jointed Stalks, do make a very grand Figure in the Borders of large Gardens, late in the Seaſon, when few other Plants are in Beauty.

The Seeds thereof ſhould be ſown in *Autumn*, as ſoon as they are ripe; or if they are permitted to fall on the Ground, the Plants will come up the *Spring* following better than when they are ſown by Art, as was before obſerved: for if the Seeds are ſown in the *Spring*, it is very rare that any of them ſucceed; and if ſome few Plants do come up from thoſe Seeds ſown at that Seaſon, they ſeldom grow near ſo ſtrong as thoſe which are produced from the Seeds which fell in *Autumn*; ſo that there is no other Culture required to this Plant but to tranſplant them out in the *Spring*, where they are deſigned to ſtand, which ſhould be in large Gardens, giving them great Space; for if they are placed near other Plants, they will ſhade them intirely from the Sun, and by continual dripping upon them, will greatly injure them; and if they ſtand too cloſe their Beauty is greatly diminiſhed.

When the Plants begin to aſpire upwards (which is commonly in *July)* their ſide Shoots ſhould be pruned off, to make them advance in Height, and preſerve them within Compaſs; otherwiſe they are very ſubject to branch out widely on every Side, ſo as to become troubleſome in a Garden; but when they are pruned up regularly five or ſix Feet high, they may afterwards be permitted to ſhoot out ſide Branches; ſince thoſe which are produced above that Height will never be very long or troubleſome, but will add to the Beauty of the Plant; This delights in a rich moiſt Soil, upon which it will grow to a prodigious Height; it produces its Flowers in *September*, which continue in Beauty until the Froſt deſtroys them.

PERVINCA, [ſo called of *pervincere*, Lat. to *overcome thoroughly*, becauſe it reſiſts the *Winter*'s Cold: It is alſo called *Clematis*, of Κλῆμα, to *climb*, becauſe this Plant climbs upon thoſe Plants which grow near it. It is alſo called *Daphnoides*, of *Daphne*, a *Laurel*, becauſe its Leaves reſemble the Laurel. It was called *Vinca*, becauſe Girdles were made of it at Weddings, or becauſe it is good for Virgins. It is called *Chamædaphne*, of χαμαὶ, *on the Ground*, and Δάφνη, *a Laurel*, q. d. *little Laurel*; becauſe it lies on the Ground, and its Leaves reſemble a Laurel.] Periwinkle.

The *Characters* are;

The Flower-cup conſiſts of one Leaf, which is divided into five long narrow Segments: The Flower alſo conſiſts of one Leaf, which expands in the Form of a Salver, and is cut into five broad Segments; the Pointal, which ariſes from the Center of the Flower-cup, becomes a Fruit, compoſed of two Huſks (or Pods) which contain oblong cylindrical furrow'd Seeds: To which may be added, that this Plant ſhoots out many long creeping Branches, which ſtrike out Roots at their Joints.

The *Species are*;

1. Pervinca *vulgaris anguſtifolia, flore cœruleo. Tourn.* Common *or* Narrow-leav'd Periwinkle, with a blue Flower.
2. Pervinca *vulgaris anguſtifolia, flore albo. Tourn.* Common Periwinkle, with a white Flower.
3. Pervinca *vulgaris latifolia, flore cœruleo. Tourn.* Greater Periwinkle, with a blue Flower.
4. Pervinca *vulgaris anguſtifolia, flore rubente. Tourn.* Common Periwinkle, with a reddiſh Flower.
5. Pervinca *vulgaris anguſtifolia, flore pleno, ſaturate purpureo. Tourn.* Common Periwinkle, with a double Flower, of a deep purple Colour.
6. Pervinca *anguſtifolia vulgaris variegate ex aureo & viridi. Boerh. Ind.* Common Periwinkle, with yellow ſtriped Leaves.
7. Pervinca *anguſtifolio vulgaris variegata ex argenteo & viridi. Boerh. Ind.* Common Periwinkle, with Silver-ſtrip'd Leaves.

The firſt Sort grows wild in divers Parts of *England*, and is not ſo much cultivated in Gardens at preſent as it was formerly, when it was planted for edging of Borders; but the Shoots being very apt to root at their Joints, rendered it very difficult to preſerve in any tolerable Order; and the Plants rooting deep in the Ground, do greatly exhauſt the Goodneſs of the Soil; ſo that it is now almoſt wholly caſt out of Gardens.

The ſecond and fourth Sorts are Varieties from the firſt, differing only in the Colour of their Flowers; as are alſo the ſixth and ſeventh, which differ in their variegated Leaves, for which they are preſerved in the Gardens of thoſe who admire ſtriped Plants.

The fifth Sort produces fine double Flowers, which makes a very handſome Appearance during its Seaſon of Flowering, which renders it worthy of a Place in every good Garden.

The third Sort grows much larger than the former, and produces large blue Flowers: This is found in Woods and ſhady Places in divers Parts of *England*.

All theſe Plants multiply exceedingly by their Shoots from the old Roots, which trailing upon the Ground do ſtrike out Roots in a ſhort Time, and may be taken off and tranſplanted where they are to remain; and tho' they are not ſo proper for a Flower-garden, yet a few Roots of each Sort may be planted in ſhady Borders under Trees, where few other Plants will thrive, or in ſmall Wilderneſſes; in which Places, if they are kept within Compaſs, they make a pretty Variety. The large Sort may be planted under Hedges, in Woods, *&c.* where it will grow four or five Feet high, and continue a long time in Flower.

Theſe Plants propagate themſelves by Roots ſo plentifully, that they ſeldom produce Fruit.

Monſ. *Tournefort* ſays, He could never obſerve any Fruit upon them either in the Country adjoining to *Paris*, or in *Provence* or *Languedoc*, where they are very common, or in the Neighbourhood of *Liſbon*.

Of all the Botanical Writers before *Tournefort*, *Cæſalpinus* is the only Perſon who found and deſcribed this Fruit; which, he ſays, is oblong, being two forked Huſks, arched and conjoined at their Extremities, containing, for the moſt part, two oblong Seeds in each.

To have this Plant produce Fruit, Monſ. *Tournefort* adviſes its being planted in a Pot that contains but a ſmall Quantity of Earth; ſo that the Sap being prevented from diſſipating and ſpending itſelf upon nouriſhing new Shoots, will mount the Stems, and ſwell the Pointal, which becomes the Fruit; and this, he ſays, was the Method whereby he obtained the Fruit of this Plant, of which he has given a Figure in his *Elements of Botany*.

But notwithſtanding what Monſ. *Tournefort* has related concerning this Matter, yet I have often obſerved the Fruit upon ſuch Plants as have grown ſingly on a good Soil; tho' where their Shoots are permitted to entangle with each other, and grow very cloſe, there is ſeldom any Fruit produced.

PETALS, are the fine-coloured Leaves which compoſe the moſt conſpicuous Parts of a Flower: Theſe are called in *Latin*, *Petala*, to diſtinguiſh them from the Leaves of Plants, which are called *Folia*.

PETASITES, [it takes its Name of πεταίω, to *extend*, becauſe its Leaves are very broad, or of πετάσυς, a *Cap*, becauſe its Leaves may ſerve inſtead of a Cap; for it has a certain Hollow in the Middle, and a hollow Expanſion round that; ſo that it reſembles a Bonnet] Butter-bur.

The *Characters* are;

It is a Plant with a floſculous Flower, conſiſting of many Florets, divided into many Parts, ſitting on the Embryo, and contained in a cylindrical Empalement, divided alſo into many Parts; the Embryo afterwards becomes a Seed furniſhed with Down: To which may be added, the Flowers appear before the Leaves.

The *Species* are;

1. Petasites *major & vulgaris. C. B. P.* Common Butter-bur, *or* Peſtilent-wort.
2. Petasites *major, floribus pediculis longis inſidentibus. Raii Syn.* Greater Butter-bur, with long Foot ſtalks to the Flowers.
3. Petasites *albus, anguloſo folio. J. B.* White Butter-bur, with angular Leaves.
4. Petasites *minor alter, tuſſilaginis folio. H. R. Par.* Leſſer Butter-bur, with a Colt's-foot Leaf.

The firſt Sort here mentioned is uſed in Medicine: This grows wild in great Plenty by the Sides of Ditches, and in moiſt Soils, in divers Parts of *England*. The Flowers of this Plant appear in the Beginning of *March*; and after they are paſt, the green Leaves come up, and grow to be very large.

The ſecond Sort was found by Mr. *Jacob Bobart* in *Oxfordſhire*, and ſent to the *Phyſic Garden* at *Chelſea*: This differs greatly from the former in its manner of Flowering; for the Flower-ſtems of this Sort riſe near two Feet high, and the Flowers grow upon long Foot-ſtalks; whereas the Stems of the common Sort do ſeldom riſe above eight or ten Inches high, and the Flowers do cloſely ſurround the Stalks.

The other two Sorts are preſerved in Botanick Gardens for Variety; but as they have little Beauty, ſo they are ſeldom propagated in other Gardens: They do all of them increaſe greatly by their creeping Roots, and, if placed in a moiſt Soil, will in a ſhort Time over-run a large Compaſs of Ground.

PETIVERIA, Guinea Henweed *vulgo*.

The *Characters* are;

It hath a Flower conſiſting of four Leaves, which are placed almoſt in the Form of a Croſs, from whoſe Cup riſes the Pointal, which afterward becomes the Fruit, which is bordered and cut at the Top, reſembling an inverſed Shield containing oblong Seeds.

We know but one *Species* of this Plant, *viz.*

Petiveria *ſolani foliis, loculis ſpinoſis. Plum. Nov. Gen.* Petiveria with Nightſhade Leaves, and prickly Seed-veſſels, commonly called *Guinea* Henweed.

This Name was given to this Plant, by Father *Plumier*, who diſcovered it in *America*; in Honour to Mr. *James Petiver* an Apothecary, who was a curious Botaniſt.

It is a very common Plant in *Jamaica*, *Barbadoes*, and moſt of the other Iſlands in the *Weſt-Indies*, where it grows in ſhady Woods, and all the *Savannas*, in ſuch Plenty, as to become a very troubleſome Weed; and as this Plant will endure a great deal of Drought, ſo it remains green, when other Plants are burnt up, which occaſions the Cattle to brouze on it; and having a moſt unſavoury ſtrong Scent, ſomewhat like wild Garlick, it gives the Cows Milk the ſame Flavour; and the Cattle which are killed ſoon after feeding on this Plant, have a moſt intolerable Scent, ſo that their Fleſh is good for little.

In *Europe* this Plant is preſerved in the Gardens of thoſe Perſons who are curious in Botany, but there is little Beauty in it; and having ſo ſtrong rank a Scent upon being handled renders it leſs valuable. It is propagated by Seeds, which muſt be ſown in a Hot-bed early in the Spring; and when the Plants are come up, they ſhould be each tranſplanted into a ſeparate Pot, and plunged into a moderate Hot-bed to bring them forward. When the Plants have obtained a good Share of Strength, they ſhould be inured to bear the open Air by degrees; into which they may be removed toward the latter End of *June*, placing them in a warm Situation, where they may remain till *Autumn*, when they ſhould be removed into the Stove, and in Winter muſt have a moderate Degree of Warmth, otherwiſe they will not live in this Country.

Theſe Plants will grow woody, and ſhoot out many Side-branches, but ſeldom riſe above two Feet high. They will produce Flowers and Seeds every Summer, and will continue ſeveral Years, remaining conſtantly green throughout the Year.

PETROSELINUM: *vide* Apium.

PEUCEDANUM [Πευκέδανον, of Πεύκη, the *Pine-tree*, becauſe the Leaves ſeem to reſemble the Pine-tree.] Hogs-fennel.

The *Characters* are:

It is a Plant with a Roſe and umbellated Flower, conſiſting of many Petals placed orbicularly, and reſting on the Empalement, which becomes a Fruit compoſed of two Seeds, which are almoſt plain, oval, gently ſtreak'd, and border'd: to theſe Marks muſt be added, that the Leaves are winged, narrow, graſſy, and divided into three Segments.

The *Species* are;

1. PEUCEDANUM *majus, Italicum. C. B. P.* Greater Hogs-fennel.
2. PEUCEDANUM *minus Germanicum. J. B.* Leſſer *German* Hogs-fennel *or* Sulphur-wort.

There are ſeveral other *Species* of this Plant, which are preſerv'd in ſome curious Botanick Gardens; but as they are Plants of little Beauty or Uſe, ſo it would be needleſs to enumerate their ſeveral Varieties in this Place.

The firſt Sort here mention'd is not very common in *England*, being only to be found in ſome curious Gardens: but the ſecond Sort (which is directed to be uſed in Medicine) is found wild in watery Places, in ſeveral Parts of *England*.

Theſe Plants may be cultivated by ſowing their Seeds on a moiſt Soil in the *Autumn*, ſoon after they are ripe, in which Place they will come ſtrong the ſucceeding *Spring*, when they ſhould be carefully weeded, and drawn out, where they are too cloſe, otherwiſe they will draw each other up very weak; and the *Autumn* following they may be taken up, and tranſplanted where they are to remain, in which Place they ſhould be planted at leaſt two Feet aſunder; for their Roots will grow very large, and branch out greatly, when they have acquired Strength. The ſecond Year after ſowing, they will produce Flowers and Seeds; but the Roots will abide many Years.

PHALANGIUM, [this Plant is ſo call'd, becauſe the Ancients uſed it in curing the pricking or ſtinging of Spiders, *Tarantula*] Spider-wort.

The *Characters* are;

It is a Plant with a Lily Flower, compoſed of ſix Petals, from whoſe Center riſes the Pointal, which afterwards becomes a roundiſh Fruit, divided into three Cells, and full of angular Seeds: to theſe Marks muſt be added, a fibroſe Root, in order to diſtinguiſh it from the Ornithogalum.

The *Species* are;

1. PHALANGIUM *parvo flore, ramoſum. C. B. P.* Branched Spider-wort, with a ſmall Flower.
2. PHALANGIUM *parvo flore, non ramoſum. C. B. P.* Unbranch'd Spider-wort, with a ſmall Flower.
3. PHALANGIUM *Africanum, floribus luteis parvis. Raii Hiſt.* African Spider-wort, with ſmall yellow Flowers.
4. PHALANGIUM *parvo flore, ramoſum, foliis fiſtuloſis, annuum. H. L.* Annual-branching Spider-wort, with fiſtulous Leaves, and a ſmall Flower.
5. PHALANGIUM *Africanum, foliis cepaceis, floribus ſpicatis aureis. Boerh. Ind.* African Spider-wort, with Onion Leaves, and Golden Flowers, growing in Spikes, *falſely call'd* an Aloe.
6. PHALANGIUM *Æthiopicum, ramoſum, floribus albis, petalis reflexis. Hort. Amſt.* Branchy *Ethiopian* Spider-wort, with white Flowers, whoſe Petals are turn'd backward.

The firſt and ſecond Sorts are abiding Plants, which are propagated in curious Gardens, for the ſake of their Flowers; and tho' they are not very beautiful, yet for their long Continuance in Flower, they deſerve a Place in the open Borders of every curious Flower-Garden.

Theſe may be propagated either from Seeds, or by parting their Roots. The beſt Time to ſow the Seeds is in *Autumn*, ſoon after they are ripe, in the Manner directed for bulbous-rooted Flowers, with which theſe Plants do agree in their Culture, and the ſecond Year after ſowing they will produce Flowers. The Seaſon for parting their Roots is in *September*; in doing of which, you muſt obſerve to preſerve a good Head to each Off-ſet, and not to divide them too ſmall, which will cauſe them to flower weak the following *Summer*: they delight in a freſh light Earth, and an open Situation.

The third Sort is an annual Plant, which ſhould be ſown on a Bed of light Earth, in *March*; and when the Plants are come up, they muſt be tranſplanted where they are to remain, in which Place they muſt be kept clear from Weeds, which is all the Culture they require: they produce their Flowers in *July*, and their Seeds are perfected in *Auguſt*.

The fourth Sort is alſo annual, but grows very large, in compariſon to the laſt: this commonly riſes two Feet high, and divides into many Branches, each of which produces a Spike of Flowers: it is a very hardy Plant; and if the Seeds are permitted to fall in *Autumn*, they will come up in the *Spring*, and produce much ſtronger Plants, than if ſown at that Seaſon, and will flower much ſooner: this muſt have a light dry Soil.

The fifth Sort is preſerv'd in Green-houſes, with other ſucculent Plants, amongſt which it makes a pretty Variety, there being ſcarcely a Month in the Year when there are not ſome of the Spikes of Flowers in Beauty. This was formerly call'd an *Aloe*, which Name is ſtill retain'd by unſkilful Perſons, tho' it is vaſtly different therefrom, in its whole Appearance. This Plant multiplies very faſt by Off-ſets, which, tho' produced at ſome Diſtance from the Earth, yet do emit Roots of a conſiderable Length; and when planted, do immediately take in the Earth: they ſhould be planted in Pots of light ſandy Earth, and houſed in Winter, with *Ficoides's*, and other hardy ſucculent Plants, where they may have free open Air; for they are hardy, and require only to be protected from Froſt.

The ſixth Sort is alſo preſerved in ſome curious Gardens, with other Exotick Plants, in the Green-houſe: this is multiplied by parting the Roots; the beſt Seaſon for doing this is in *Auguſt*, when the Leaves are decay'd; they ſhould be planted in Pots fill'd with light ſandy Earth, and houſed in Winter with the laſt: this produces large-branching Stems, which are thinly beſet with Flowers, that have their Petals reflex'd, and are of a whitiſh Colour, but continue a long time in Beauty.

PHASEOLOIDES, [of *Phaſeolus*, Lat. and εἶδος, *Shape*] Kidney-bean Tree: *vulgo*.

The *Characters* are;

It hath a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a long Pod, incloſing ſeveral Seeds, which are ſhaped almoſt like a Kidney: to which muſt be added, that it hath pennated Leaves, conſiſting of an unequal Number of Lobes, which diſtinguiſhes it from Phaſeolus.

We have but one *Species* of this Plant, at preſent, in *England*; which is,

PHASEOLOIDES *Carolinianum fruteſcens ſcandens, foliis pinnatis, floribus cœruleis ſpicatis.* Carolina Kidney-bean Tree: *vulgo*.

The Seeds of this Plant were ſent from *Carolina* by Mr. *Catesby*, in the Year 1724. and diſtributed to ſeveral curious Perſons in *London*; from which many Plants have been raiſed, which are very hardy, and propagate very eaſily by laying down the tender Branches, or from Suckers, which are ſent from the Root in great Plenty.

The beſt Seaſon for tranſplanting theſe Plants is in the *Spring*, juſt before they ſhoot: they will grow in almoſt any Soil, but thrive beſt in a rich light Earth.

This Plant is very proper to place among other climbing Shrubs in ſmall Wilderneſs Quarters, where, if it be ſupported with ſtrong Stakes, it will riſe twelve or fourteen Feet high, and produce many Spikes of fine blue Flowers; and if the Seaſon prove favourable, the Seeds will ripen very well: it is extreme hardy, enduring the ſevereſt Cold of our Climate in the open Air, provided it be not too much expoſed to the cold Winds.

PHASEOLUS, [takes its Name from φάσηλος, a *long ſwift Ship*, becauſe the Huſk of this Plant reſembles ſuch a Ship] Kidney-bean.

The *Characters* are;

It is a Plant with a papilionaceous Flower, out of whoſe Empalement riſes the Pointal, which afterwards becomes a long Pod, pregnant with Seeds, for the moſt part ſhaped like a Kidney or Oval: to theſe Notes are to be added, Leaves growing by Three's on each Pedicle, and the Plant for the moſt part climbing.

It would be to little Purpoſe to enumerate all the Varieties of this Plant which have come to Knowledge, in this Place; ſince *America* does annually furniſh us with new Sorts, ſo that there is no knowing what Varieties there may be produced in *England:* beſides, as they are not likely to be much cultivated here, ſince the old Sorts are preferable to any of the new ones, for the Kitchen; therefore I ſhall only firſt ſet down a few Sorts which are cultivated for their Flowers, or as Curioſities, and then mention thoſe which are moſt eſteem'd for the Table.

1. PHASEOLUS *Indicus, flore coccineo, ſeu puniceo. Mor. Hiſt.* The Scarlet Bean.
2. PHASEOLUS *Americanus perennis, flore cochleato odorato, ſeminibus fuſcis orbiculatis, Caracalla dictus. H. L.* Perennial American Kidney-bean, with ſweet-ſmelling cochleated Flowers, *commonly call'd* Caracalla.
3. PHASEOLUS *Americanus, ſtrumoſa radice, flore purpureo, ſiliqua anguſtiſſima. Plum.* American Kidney-bean, with a ſtrumoſe Root, a purple Flower, and a very narrow Pod.
4. PHASEOLUS *Canadenſis purpureus minor, radice vivaci. Schol. Bot.* Small purple Kidney-bean, with a perennial Root.
5. PHASEOLUS *arbor Indica incana, ſiliquis toroſis, Kayan dicta. Raii Hiſt.* Indian Hoary-Tree Kidney-bean, with ſwelling knotted Pods, *commonly call'd* Pigeon-Pea.

The firſt of theſe Plants is very common in the *Engliſh* Gardens, being planted for the Beauty of its ſcarlet Flowers: this Plant ſpreads itſelf very far, ſo that it ſhould be allow'd Room, otherwiſe it will over-run whatever Plants grow near it. The Seaſon for planting the Seeds of this Plant is in the Beginning of *April*, obſerving always to do it in dry Weather, otherwiſe the Seeds will burſt and rot: they will produce their Flowers by the Beginning of *July*, and will continue flowering until the Froſt prevents them; and their Seeds will ripen in *September*, when they ſhould be gather'd, and preſerv'd in a dry Place until the ſucceeding *Spring*, in order to be ſown. This Plant being annual, periſhes with the firſt Approach of *Winter:* it will thrive very well in the City, the Smoak of the Sea-coal being leſs injurious to this Plant than moſt others, ſo that it is often cultivated in Balconies, &c. and being ſupported either with Sticks or Strings, grows up to a good Height, and produces its Flowers very well: it is alſo planted in ſome Gardens, to cover Arbors and other Seats in the *Summer* Seaſon, to afford Shade, for which Purpoſe it will do very well: but the Seeds muſt be put in where they are to remain; for the Plants don't bear to be tranſplanted well.

The ſecond Sort is an abiding Plant, which may alſo be propagated by Seeds, which ſhould be ſown in a moderate Hot-bed in the *Spring*; and when they come up, they muſt be carefully tranſplanted into Pots fill'd with light freſh Earth, which muſt be plung'd into a Hot-bed, to facilitate their taking Root; after which, they ſhould be inured to bear the open Air by Degrees, into which they ſhould be removed when the Seaſon is warm, placing them in a ſhelter'd Situation; and as they advance, ſo ſhould they be removed into larger Pots, which muſt be fill'd up with freſh light Earth.

During the *Summer* Seaſon it muſt be frequently refreſh'd with Water; but in *Winter* it muſt be removed into the Green-houſe, and ſhould have but little Water during that Seaſon. It requires only to be ſcreen'd from Froſt; but muſt have open free Air whenever the Weather will permit, otherwiſe the Leaves will grow mouldy, and decay the tender Shoots: it produces its ſcarlet Flowers in *July* and *Auguſt*, but ſeldom perfects its Seeds in this Country. This Plant is very common in *Portugal*, where it is planted to cover Arbors and Seats in Gardens, for which it is greatly eſteem'd by the Inhabitants of that Country, and for its beautiful ſweet-ſmelling Flowers; and in that Country it thrives very well in the open Air.

The third Sort is preſerv'd in ſome curious Gardens for Variety; but is a Plant of no great Beauty: this may be propagated by ſowing the Seeds in the *Spring* upon a Hot-bed, and when they come up, they muſt be planted in Pots, and treated as the former Sort: it produces its Flowers in *July*, and the Seeds ripen in *September*.

The fourth Sort was brought from *America*, and is preſerv'd in curious Gardens, for the ſake of its long Flowering: this is an abiding Plant, and ſhould be managed as was directed for the third Sort; and if guarded from Froſt will continue to produce Flowers all the *Winter* Seaſon: it ripens Seeds very well, from which the Plants may be eaſily propagated.

The fifth Sort is preſerv'd as a Curioſity in *England:* but in the *Weſt-Indies* it is frequenly planted by the Sides of Alleys in Gardens, to form a Hedge, where they will laſt many Years without decaying; and will thrive on barren Land which has been worn out, where ſcarcely any thing elſe will proſper, and produce a great Quantity of Fruit, which are ſometimes eaten by the Inhabitants; but their chief Uſe is to feed Pigeons, from whence this Plant had its Name. The Branches, with the ripe Peas and Leaves, are given to Hogs, Horſes, and moſt other Cattle, which fattens them very much. In *England* it is preſerv'd in Stoves, being too tender to be kept without artificial Heat in this Climate: it may be propagated from Seeds, (which are generally brought from the *Weſt-Indies* every Year in great Plenty;) and when the Plants come up, they ſhould be planted into Pots fill'd with light ſandy Earth, and plunged into a Hot-bed, to promote their Growth: but when they have acquired ſtrength, they ſhould be gradually inured to the open Air, into which they may be removed in *July*, and may remain abroad until the Beginning of *September*, when they muſt be removed into the Stove, placing them where they may have a moderate Heat, obſerving to refreſh them now and then with a little Water; but be very careful not to give it to them in great Quantities, (eſpecially at that Seaſon) which will be very apt to rot their Roots: the ſecond Year theſe Plants will flower early in the *Spring*, and do many times produce ripe Fruit.

There are at preſent but three Sorts of *Kidney-beans*, which are cultivated for the Table in *England:* which are;

1. The Common White *or* Dutch Kidney-bean.
2. The Leſſer Garden Kidney-bean, *commonly call'd*, The *Batterſea* Bean.
3. The Upright *or* Tree Kidney-bean.

The firſt of theſe was formerly more cultivated in *England* than at preſent; but is the chief Sort now cultivated in *Holland*, from whence, probably, it had the Name of *Dutch Kidney-bean:* This Sort riſes to a very great Height, and requires to be ſupported by tall Stakes, otherwiſe they will ſpread upon the Ground, and rot; ſo that where this Care is wanting, the Fruit ſeldom comes to good: which Trouble renders it difficult to cultivate this Sort in Plenty; and the Beans being much broader than the ſmall Sort, render them leſs valuable in the *London* Markets; which, I ſuppoſe, occaſion'd their being neglected in *England:* but this is by far the beſt Sort for Eating yet known.

The ſecond Sort is that which is moſt commonly cultivated in the Gardens near *London*, and is by far the beſt Sort we yet know; for the Plant never rambles too far, but is always of moderate Growth, ſo that the Air can eaſily paſs between the Rows, and keep them from rotting: it is alſo a plentiful Bearer, and the beſt Bean, except the laſt, for Eating.

The third Sort is alſo a plentiful Bearer, and never rambles, growing upright in form of a Shrub; but the Beans are much larger than the laſt, and are not ſo well colour'd, nor do they eat near ſo firm and criſp; for which Reaſons they are not ſo generally eſteem'd.

Theſe Plants are propagated from Seeds, which muſt be ſown in the Place where they are to remain; for they will not bear tranſplanting, except it be done while they are very young; and this being pretty troubleſome, is very ſeldom practiſed, unleſs for a few early Plants under warm Hedges or Walls; but it is not worth while for the general Crops.

The Seaſon for putting theſe Seeds in the Ground, is the latter End of *March*, or the Beginning of *April*, for an early Crop; but theſe ſhould have a warm Situation, and a dry Soil, otherwiſe they will not ſucceed: you ſhould alſo obſerve to put them into the Ground at a dry Seaſon; for Wet ſo early in the Seaſon will rot the Seeds in the Ground. The Manner of planting them, is, to draw ſhallow Furrows with a Hough, at about two Feet and an half Diſtance from each other, into which you ſhould drop the Seeds about two Inches aſunder; then with the Head of a Rake draw the Earth over them, ſo as to cover them about an Inch deep.

If the Seaſon be favourable, the Plants will begin to appear in about a Week's time after ſowing, and ſoon after will raiſe their Heads upright; therefore if the Stems thereof are pretty tall above Ground, you ſhould gently draw a little Earth up to them, obſerving to do it when the Ground is dry, which will preſerve them from being injured by ſharp Winds: but you ſhould be careful not to draw any of the Earth over their Leaves, which would rot them, or at leaſt greatly retard their Growth. After this, they will require no farther Care but to keep them clear from Weeds until they produce Fruit, when they ſhould be carefully gather'd two or three times a Week; for if they are permitted to remain upon the Plants a little too long, the Beans will be too large for eating, and the Plants wou'd be greatly weaken'd thereby.

This firſt Crop of *Kidney Beans* will continue a Month in good Order, during which time they will produce great Plenty of Beans; therefore, in order to have a Succeſſion of them throughout the Seaſon, you ſhould ſow at three different Times, *viz.* in *March* or *April*, in *May*, and toward the Latter-end of *June*; which laſt Crop will continue until the Froſt comes on, and deſtroys 'em.

There are ſome Perſons who raiſe theſe in Hot-beds, in order to have them very early: The only Care to be taken in the Management of theſe Plants, when thus rais'd, is to allow them Room, and give 'em as much Air as can be conveniently, when the Weather is mild; as alſo to let 'em have but a moderate Heat; for if the Bed be over-hot, they will either burn, or be drawn up ſo weak as never to come to good.

The Manner of making the Hot-bed being the ſame as for *Cucumbers*, &c. need not be repeated in this Place: but only obſerve, when the Dung is equally levell'd, to lay the Earth about four or five Inches thick; and let the great Steam of the Bed paſs off before you ſow the Seeds: The Time for doing this, muſt be proportion'd to the Seaſon when you would have the Beans for the Table; but the ſureſt Time for a Crop, is about a Week in *February*.

It is alſo a good Method which ſome uſe, to have *French Beans* earlier than they can be obtain'd in the common Ground, To make a gentle Hot-bed about the Middle of *March*, which may be arched over with Hoops, and cover'd with Mats; in this they ſow their *Kidney Beans* in Rows pretty cloſe together, ſo that a ſmall Bed will contain a great Number of Plants; theſe they bring up hardily, inuring 'em to the open Air by Degrees; and in the Beginning of *April*, when the Weather is ſettled, they prepare ſome warm Borders under Walls or Hedges; then they take them up from the Hot-bed, preſerving as much Earth as poſſible to their Roots, and plant them in the Borders at the Diſtance they are to remain: Theſe, if they take Root kindly, will produce Beans at leaſt a Fortnight before thoſe ſown in the common Ground.

The Manner of ſaving the Seeds of theſe Plants, is to let a few Rows of them remain ungather'd in the Height of the Seaſon; for if you gather from the Plants for ſome time, and afterwards leave the Remaining for Seed, their Pods will not bear ſo long and handſome, nor will the Seed be ſo good: In the *Autumn*, when you find they are ripe, you ſhould in a dry Seaſon pull up the Plants, and ſpread them abroad to dry; after which, you may threſh out the Seed, and preſerve it in a dry Place for Uſe.

PHILLYREA; [φιλύρα] Mock-privet.

The *Characters* are;

The Leaves grow by Pairs oppoſite to each other, and are Ever-green; the Flower conſiſts of one Leaf, is Bell-ſhap'd, and divided into four Parts at the Top; the Pointal, which riſes from the Center of the Flower-cup, afterwards becomes a ſpherical Flower containing one round Seed.

The *Species* are;

1. PHILLYREA *latifolia lævis. C. B. P.* The Broad-leav'd true *Phillyrea*.

2. PHILLYREA *latifolia ſpinoſa. C. B. P.* Ilex-leafed *Phillyrea*, vulgo.

3. PHILLYREA *folio alaterni. J. B. Phillyrea*, with an Alaternus Leaf.

4. PHILLYREA *folio liguſtri. C. B. P.* Privet-leafed *Phillyrea*.

5. PHILLYREA *anguſtifolia prima. C. B. P.* Narrow-leafed *Phillyrea*.

6. PHILLYREA *anguſtifolia ſecunda. C. B. P.* Roſemary-leafed *Phillyrea*, vulgo.

7. PHILLYREA *oleæ Epheſiacæ folio. Hort. Chelſ. Pluk. Phyt.* Olive-leafed *Phillyrea*.

8. PHILLYREA *latifolia lævis, foliis ex luteo variegatis. Cat. Plant. Hort.* The true *Phillyrea*, with ſtrip'd Leaves.

9. PHILLYREA *longiore folio, profunde crenato. H. R. Par. Phillyrea* with a longer Leaf, which is deeply crenated.

10. PHILLYREA *folio buxi. H. R. Par.* Box-leafed *Phillyrea*.

11. PHILLYREA *Hiſpanica, lauri folio ſerrato & aculeato. Inſt. R. H. Spaniſh Phillyrea*, with a prickly and ſawed Bay-leaf.

12. PHILLYREA *Hiſpanica, nerii folio. Inſt. R. H. Spaniſh Phillyrea*, with an oleander Leaf.

13. PHILLYREA *Capenſis, folio celaſtri. Hort. Elth. Phillyrea* of the *Cape of Good Hope*, with a Staff-tree Leaf, commonly called by the *Dutch*, *Lipplehout*.

14. PHILLYREA *Americana humilis, radice craſſâ luteâ, foliis acuminatis. Plum. Cat.* Dwarf *American Phillyrea*, with a thick yellow Root, and pointed Leaves.

15. PHILLYREA *Americana humilis, radice craſsâ roſeâ, foliis rotundioribus. Plum. Cat.* Dwarf *American Phillyrea*, with a thick roſe-coloured Root, and rounder Leaves.

The firſt eight of theſe Plants are moſt of them Natives of the Southern Parts of *France*, *Spain* and *Italy*, but are hardy enough to endure the Cold of our Climate in the open Air: They have been formerly in great Requeſt for Hedges, and to cover Walls, for both which Purpoſes they are very improper; becauſe they ſhoot ſo faſt in the *Spring* and *Summer* Months that it is very troubleſome to keep ſuch Hedges in Order; beſides, all theſe Sorts with broad Leaves do naturally produce their Branches ſo far aſunder, that they can never be reduced to a thick handſome Hedge; for although by frequently clipping the extreme Parts of the Shoots you force out ſome ſide Branches, which render it thick on the Outſide, yet the inner Branches are very far aſunder, and being of a pliable Nature are often diſplaced by ſtrong Winds; or if there happen to fall much Snow in *Winter*, ſo as to lie upon theſe Hedges, it often diſplaces them ſo much as not to be recovered again in ſome Years; for which Reaſons they are not ſo much in uſe for Hedges as they were ſome Years paſt: Nor are they ſo often planted to cover Walls; for it is a very difficult Taſk to keep them cloſe to the Wall; for their Branches being vigorous, do commonly grow to ſome Diſtance from the Wall, and harbour all Sorts of Inſects and Filth: Beſides, their Leaves being large, and growing pretty far aſunder upon the Branches, they appear naked, eſpecially when they are kept cloſely clipt.

But all theſe Sorts of Trees are very proper to intermix with other Ever-greens, to form Clumps, Amphitheatres, or to plant round the Sides of Wilderneſſes of Ever-green Trees, where being placed among other Trees of the ſame Growth, they will afford a pleaſing Variety.

The three firſt Sorts will grow to the Height of twenty Feet or more, and may be trained up to regular Heads; but the narrow-leafed Sorts ſeldom riſe above fourteen or ſixteen Feet high with us; ſo that they will be of a proper Size to place in a Line before the broad-leafed Sorts, where being intermixed with *Hollies*, *Alaternus's*, *Arbutus's*, and ſome other Sorts, they will make a beautiful Proſpect.

Theſe Plants are propagated either from Seeds or Layers; but the latter being the moſt expeditious Method in *England*, is chiefly preferred: The beſt Time to lay them down is in *March*, when you ſhould dig the Ground round the Plants intended to lay, making it very looſe; then making choice of a ſmooth Part of the Shoot, you ſhould make a Slit upwards (in the manner as is practiſed in laying of *Carnations*) and then bend the Branch gently down to the Ground, making a hollow Place with your Hand to receive it, and having placed the Part which was ſlit in the Ground, ſo as that the Slit may be open, you ſhould faſten it down with a forked Stick, that it may remain ſteady, covering that Part of the Branch with Earth about three Inches thick, obſerving to keep the upper Part erect. In dry Weather theſe Layers ſhould be watered, which will greatly facilitate their rooting; you muſt alſo keep them clear from Weeds, which if ſuffered to grow up amongſt them, will prevent their taking Root.

The *March* following many of theſe Plants will be rooted, at which time they may be taken off, and carefully planted in a Nurſery, where they may be trained up three or four Years in the manner you intend them to grow; during which time you ſhould dig the Ground between the Rows, and cut about the Roots of the Plants every Year, which will cauſe them to ſtrike out ſtrong Fibres, ſo as to ſupport a good Ball of Earth when they are removed; you ſhould alſo ſupport their Stems with Stakes, in order to make them ſtrait, otherwiſe they are very apt to grow crooked and unſightly.

When the Plants have been thus managed three or four
